ENCYCLOPÆDIA BRITANNICA.

EIGHTH EDITION

~~X.207.c.~~

National Library of Scotland
B000355874

EB 16

In Quarto, Cloth, Price 24s.,

ENCYCLOPÆDIA BRITANNICA.

EIGHTH EDITION. VOL. XVIII.

ILLUSTRATED BY NUMEROUS ENGRAVINGS,

AND CONTAINING, AMONGST OTHER IMPORTANT ARTICLES, THE FOLLOWING:—

PLAYFAIR (John). By Lord Jeffrey.
PNEUMATICS. By Sir John Robison, late Professor of Natural Philosophy in the University of Edinburgh.
POETRY. By George Moir, Advocate. Revised by W. Edmonstoune Aytoun, Professor of Rhetoric and Belles Lettres in the University of Edinburgh.
POISON. By Robert Christison, M.D., Professor of Materia Medica in the University of Edinburgh.
POLAND. By James Browne, LL.D. Revised.
POLAR REGIONS. By Sir John Richardson, K.B.
POLICE, and POST-OFFICE. By Edward Edwards, Author of the article "Libraries."
POLITICAL ECONOMY, and PRECIOUS METALS. By J. R. M'Culloch.
POLYNESIA. By the Rev. W. Ellis, Author of the article "Madagascar."
POOR-LAWS. By George Coode.
POPE. By Thomas de Quincey.
POPULATION. By the Rev. T. R. Malthus, late Professor of Political Economy, East India College, Hertford.
POTTERY, and PORCELAIN. By Charles Tomlinson.
PRECESSION, and PROBABILITY. By Thomas Galloway, late Secretary to the Royal Astronomical Society.
PRESBYTERIANISM. By the Rev. William H. Goold, D.D.
PRESCOTT. By William Stirling, M.P.
PRINTING. By T. C. Hansard.
PRISON DISCIPLINE. By John Hill Burton.
PRUSSIA. By Dr G. Von Bunsen.
PUNJAB. By E. B. Eastwick, Author of the article "Persia."
QUAKERS. By William Howitt, Author of "Visits to Remarkable Places," &c.
QUESNAY. By J. R. M'Culloch.
QUINTILIANUS. By Frederic W. Farrar, Fellow of Trinity College, Cambridge.
RABELAIS. By Theodore Martin.
RAILWAYS. By D. K. Clark, Author of "Mechanical Engineering of Railways," &c. &c.
REGISTRATION. By James T. Hammack.

EDINBURGH: ADAM AND CHARLES BLACK.
LONDON: SIMPKIN, MARSHALL, & Co.

MESSRS ADAM & CHARLES BLACK'S

LIST OF

NEW WORKS, AND WORKS RECENTLY PUBLISHED.

I.

MARY STUART. By ALPHONSE DE LAMARTINE. 12mo. Cloth, with Portrait and Vignette. Price 5s.

II.

NEW EXEGESIS of SHAKESPEARE. Interpretation of his Principal Characters and Plays on the Principle of Races. [*Nearly ready.*

III.

BOTANY and RELIGION; or, Illustrations of the Works of God in the Structure, Functions, Arrangement, and Distribution of Plants. By J. H. BALFOUR, A.M., Regius Keeper of the Royal Botanic Gardens, and Professor of Medicine and Botany in the University of Edinburgh. With 264 Illustrations. Crown 8vo. Price 6s. 6d.

IV.

THE THEORY OF GLACIERS. By JAMES D. FORBES, D.C.L., F.R.S., Professor of Natural Philosophy in the University of Edinburgh. With Ten Plates and Twenty-nine Wood Engravings. Demy 8vo. Price 10s. 6d.

V.

THE PRINCIPLES and PRACTICE of MEDICINE. New Edition (the Third). By J. HUGHES BENNETT, M.D., Professor of the Institutes of Medicine in the University of Edinburgh. Pp. 1005, with 500 Illustrations on Wood. 8vo. Price 30s.

VI.

Vol. II. of the NEW ILLUSTRATED EDITION of the AUTHOR'S FAVOURITE EDITION of the WAVERLEY NOVELS. Fcap. 8vo. Price 4s. 6d.

VII.

The PRACTICAL ANGLER; or, The Art of Trout-Fishing more particularly applied to Clear Water. By W. C. STEWART. Third Edition. 12mo. Price 3s. 6d.

VIII.

The ANGLER AND TOURIST'S GUIDE to the RIVERS, LAKES, and REMARKABLE PLACES in the NORTHERN COUNTIES of SCOTLAND; to which is added, Instruction to Young Anglers. By ANDREW YOUNG, Invershire, Sutherlandshire. 18mo. Price 2s.

IX.

The HORSE and the HOUND: their various Uses and Treatment; including Practical Instructions in Horsemanship and Hunting, &c. By NIMROD. Third Edition, with numerous Illustrations. Demy 8vo. Price 10s. 6d.

X.

Vol. II. of the ENCYCLOPÆDIA BRITANNICA, RE-ISSUE, from letter A to the article Anatomy. Quarto, cloth, price 24s.; half-bound russia, 30s.

XI.

ERIC; or, LITTLE BY LITTLE. A Tale of Roslyn School. By FREDERICK W. FARRAR, Fellow of Trinity College, Cambridge. Third Edition. Crown 8vo. Price 6s. 6d.

XII.

REV. DR. GUTHRIE'S DISCOURSES from EZEKIEL. Twenty-Second Thousand. Crown 8vo. Price 7s. 6d.

XIII.

REV. DR. GUTHRIE'S DISCOURSES from the EPISTLE to the COLOSSIANS. Twelfth Thousand. Crown 8vo. Price 7s. 6d.

XIV.

REV. DR. CANDLISH'S DISCOURSES on the RESURRECTION. Fourth Thousand. Crown 8vo. Price 7s. 6d.

B000355874

EB 16

BLACK'S GUIDE BOOKS.

Just published, price 8s. 6d., a New and greatly Improved Edition (the 14th) of

BLACK'S PICTURESQUE TOURIST OF SCOTLAND. Illustrated by 176 Maps, Charts, and Views, and containing all the most recent information.

BLACK'S PICTURESQUE TOURIST OF ENGLAND. With a general Travelling Map—Charts of Roads, Railroads, and interesting Localities—engraved Views of Picturesque Scenery—and a comprehensive General Index, embracing a List of Hotels and Inns. Fourth Edition, greatly enlarged and improved, Price 10s. 6d.

BLACK'S PICTURESQUE TOURIST OF IRELAND. Illustrated by a Map of Ireland and Plans of the principal Cities. Second Edition. Price 5s.; or in Four Parts, at 1s. 6d. each.

BLACK'S GUIDE TO THE LAKES OF CUMBERLAND, WESTMORELAND, and LANCASHIRE. Ninth Edition. Including an Essay on the Geology, by JOHN PHILLIPPS, M.A., F.R.S., F.G.S. With 12 Outline Views by Mr Flintoft, and numerous Illustrations. Price 5s. Extra Illustrated Edition, 7s. 6d. Cheap Edition, 1s. 6d.

BLACK'S GUIDE TO WALES (NORTH AND SOUTH) AND MONMOUTHSHIRE. Illustrated by Maps, Charts, and Views of Scenery. Eighth Edition. Price 5s.

NORTH WALES separately, price 3s. 6d.

ANDERSON'S GUIDE TO THE HIGHLANDS AND ISLANDS OF SCOTLAND, including ORKNEY and ZETLAND, descriptive of their Scenery, Statistics, Antiquities, and Natural History. Third Edition. Price 10s. 6d.

BLACK'S COUNTY GUIDES:—DERBYSHIRE, 2s. HAMPSHIRE, 2s.

DEVON AND CORNWALL. 2s.

GLOUCESTER AND HEREFORD. [*In the Press.*

YORKSHIRE. 2s. 6d.; Cloth, 3s.

THE TROSACHS, PERTHSHIRE, ARGYLESHIRE, STAFFA, IONA, AND GLENCOE, ABERDEEN and BRAEMAR, MOFFAT, each, 1s. and 1s. 6d.

GLASGOW AND ENVIRONS. 1s. and 2s. 6d.

EDINBURGH AND ENVIRONS. 1s. and 3s. 6d.

TRAVELLING MAPS.

ENGLAND AND WALES. 4s. 6d., 2s. 6d., and 1s.

ENGLISH LAKES. 2s. 6d. and 8d.

WALES (NORTH AND SOUTH). 1s. 6d. each.

SCOTLAND. 4s. 6d., 2s. 6d., and 1s.

IRELAND. 2s. 6d.

COUNTIES OF SCOTLAND. 1s. each.

TOURIST'S AND SPORTSMAN'S COMPANION TO THE COUNTIES OF SCOTLAND. A Series of 31 Maps, showing all the Roads, Railways, Villages, Country Seats, Rivers, and Lakes, &c. &c. In a portable volume, price 10s. 6d.

EDINBURGH: ADAM & CHARLES BLACK.

~~X 207 c~~

GARDENING, BOTANY, AND GEOLOGY.

In 12mo, sewed, price 1s.,

THE COTTAGE GARDEN. By Robert Adamson, Gardener, Balcarres, Colinsburgh, Fifeshire.

In foolscap 8vo, price 3s. 6d., with illustrated Frontispiece and Title,

THE AMATEUR GARDENER'S YEAR BOOK. A Guide for those who Cultivate their Own Gardens in the Principles and Practice of Horticulture. By Rev. Henry Burgess, LL.D. and Ph.D., &c.

> "This is, beyond compare, the best work of its class that has come under our notice. It is really popular."—*Critic.*

Fifth Edition, improved, with Additions, price 3s. 6d.,

NEILL'S FRUIT, FLOWER, AND KITCHEN GARDEN.

> "In Horticultural literature no book has acquired a higher reputation than the late Dr Neill's concise and popular treatise on Practical Gardening. It is copiously illustrated; and no gardener, be he amateur or professional, great or small, whether he grows pines or only potatoes, should be without it."—*Morning Post.*

In One large Volume, 8vo, with 1800 Illustrations, price 31s. 6d.,

CLASS-BOOK OF BOTANY. Being an Introduction to the Study of the Vegetable Kingdom. By J. H. Balfour, A.M., M.D., F.R.SS.L. and E., F.L.S., Regius Keeper of the Royal Botanic Garden, and Professor of Medicine and Botany in the University of Edinburgh.

The same may also be had in Two Parts:—

PART I.—STRUCTURAL and MORPHOLOGICAL BOTANY. 8vo, 10s. 6d.

PART II.—COMPRISING the ELEMENTS of VEGETABLE PHYSIOLOGY, CLASSIFICATION, BOTANICAL GEOGRAPHY, and FOSSIL BOTANY, with a GLOSSARY OF TERMS. 8vo, 21s.

> "In Dr Balfour's 'Class-Book of Botany,' the Author seems to have exhausted every attainable source of information. Few, if any, works on this subject contain such a mass of carefully collected and condensed matter, and certainly none are more copiously or better illustrated."—*Hooker's Journal of Botany.*

By the same Author,

In foolscap 8vo, 7s. 6d., illustrated by 595 Wood Engravings,

OUTLINES OF BOTANY. Being an Introduction to the Study of the Structure, Functions, Classification, and Distribution of Plants, with a Glossary and copious Index.

> "The book is admirably fitted for a text-book in teaching the science. It is beautifully illustrated, and is the cheapest botanical work of merit which has appeared."—*Scottish Guardian.*

In Crown 8vo, price 8s. 6d.,

THE STUDENT'S MANUAL OF GEOLOGY. By J. B. Jukes, M.A., F.R.S., Local Director of the Geological Survey of Ireland, and Lecturer on Geology to the Museum of Irish Industry.

> "Undoubtedly one of the most valuable aids to the practical study of Geology that has appeared of late years."—*Mining Journal.*
>
> "The whole idea of this 'Manual' indicates great clearness of thought; and a perusal shows us that the Author is not only perfectly acquainted with his subject, but that his soul is in the study of his science."—*Athenæum.*

In 12mo, cloth, price 5s.,

ELEMENTS OF MINERALOGY: Containing a General Introduction to the Science, with Descriptions of the Species. By James Nicol, F.G.S., Professor of Natural History in Marischal College and University, Aberdeen.

> "We cannot say more in favour of Professor Nicol's book, than that it professes to afford precisely the information which every practical man should possess, and that it accomplishes as much as it professes."—*Mining Journal.*

ENCYCLOPÆDIA BRITANNICA.

PLATOMETER (πλατυς, *broad*, *μέτρον*, *a measure*) is the name of an instrument invented by Mr John Sang, Kirkcaldy, 24th December 1851, the principal feature of which is the employment of a cone acting on an index-wheel, from which is read off the area of any figure whose outline has been followed by the tracer of the instrument. It has the peculiar advantage of giving the areas of the most irregular figures with the same accuracy that it gives the areas of the most regular, and with the same facility. It will be found described and figured in the *Transactions of the Royal Scottish Society of Arts*, vol. iv.

PLATON, a celebrated archbishop of Moscow, whose family name was *Leoshin*, was born 24th June 1737. He was the son of a priest near Moscow, and while yet a student at the university there, he was made teacher of poetry and rhetoric at the convent. He shortly afterwards entered the church; and after various stages of advancement, he was, in 1762, made rector and professor of theology. The visit of Queen Catherine II. to the St Sergius Lavra was made after her coronation in 1762, and Platon preached a discourse before her remarkable for its eloquence. So favourable was the impression, that he was at once appointed court preacher and preceptor in matters of religion to the Grand Duke, for whose instruction he drew up the *Orthodox Faith, or Outlines of Christian Theology*, esteemed the best of his works. He was created archbishop of Tver in 1770; and after a four years' residence at St Petersburg he was removed. During his residency at his new office he established a number of minor schools for religious instruction, and wrote two separate treatises, one for teachers, and the other for pupils. He had also entrusted to him the education of the Princess of Würtemberg-Stuttgart, Maria Pheodorovna, in the tenets of the Græco-Russian church. He was advanced to the see of Moscow in 1775; and in 1785 he erected a convent in Bethania, where he afterwards resided. As metropolitan of the Russian church he enjoyed the privilege of placing the crown on the Emperor Alexander at Moscow 1801. He died at Bethania during the following year, 1802. His works, printed at different times, amount in all to 20 volumes. A selection from them, consisting of the finest passages, was published in 2 volumes in 1805.

PLATTSBURG, a town of the United States of North America, state of New York, on both sides of the Saranac, at its mouth in a wide and beautiful bay on Lake Champlain, 160 miles N. by E. of Albany. It contains many good edifices, among which are the county buildings, several churches, an academy and other schools, two banks, &c. There are also saw-mills, cotton factories, and manufactories of leather, machinery, &c. Plattsburg is a military post, and a large stone barracks was recently erected in the neighbourhood, but it is not at present garrisoned. An extensive and active trade is carried on, the town being connected by railway with Montreal, and by steamers with the various other ports on the lake. The tonnage of the port, enrolled and licensed, June 30, 1852, was 6259; of which, sailing-vessels 4558 tons, steamers 1701 tons. Pop. (1850) 5618.

PLAUEN, a walled town of the kingdom of Saxony, circle of Zwickau, is built on uneven ground in a beautiful valley on the W. bank of the White Elster, 61 miles S.W. of Leipsic. On an elevated spot stands the old castle which was anciently the residence of the stewards of the empire (*Voigte des Reichs*), Plauen having been the capital of the *Voigtland*. Among the buildings of the town are several churches, hospitals, and schools. Plauen is one of the most important manufacturing towns in the kingdom, producing cotton goods, muslins, cambrics, lace, hosiery, leather, watches, philosophical instruments, and other articles. Pop. 13,812.

PLAUTUS, the greatest of the Roman comic dramatists, is almost unknown to us except by his writings. As his personal history was a matter of indifference to his contemporaries, it is not until the writings of a later period that we find even a casual reference to it. Our endeavour to reach the truth is moreover impeded by the many attributes which are generally ascribed to a comic poet, such as humble origin and personal deformity. This may account in some measure for the conflicting statements on almost every point of his life. Until the investigations of Ritschl (*De Plauti poetæ nominibus*) the poet's name was supposed to be *Marcus Accius Plautus;* but on the discovery of the palimpsest manuscript at Milan, his real name was found to be *Titus Maccius Plautus;* the one name *Maccius* having been divided into the two, *M. Accius.* The word Plautus meant in the Umbrian dialect "flat-footed." Hence perhaps the idea of deformity. In some of the manuscripts the cognomen *Asinius* is added to his name. Some have supposed that *Asinus* was the name really given him on account of his having been employed in grinding corn, a work generally performed by asses. Ritschl, however, has proved satisfactorily that Asinius is a corruption of Sarcinas, the ethnic name of the poet. Plautus is generally supposed to have been born at Sarcina, a village in Umbria, on the river Sapis (*Savio*), according to Ritschl (*De ætate Plauti*), in the year 254 B.C. As to his parentage there are two conjectures; either that he was born of slaves, and, going early to Rome, had an opportunity of associating with learned men, or that he was born of free parents who gave him a good education. For the little we know of his life we are indebted to a passage of Varro, preserved by Aulus Gellius (*Noctes Atticæ*, iii. 3.) Plautus while yet young went to Rome, where he was employed working for the actors on the stage ("in operis artificum scenicorum," a passage which does not mean, as supposed by Lessing, that he wrote plays). With the money which he gained by this means he made some commercial speculations. These failed, and Plautus was utterly ruined. He returned to Rome, where his difficulties were probably increased by the great scarcity of corn then prevailing. To support himself, he entered the service of a baker, who employed him in grinding corn with a hand-mill. At this time he composed the *Saturio*, the *Addictus*, and another play whose name is unknown. Ritschl supposes this to have been about the year 224 B.C., Plautus being thirty years of age. By these plays, and by his employment, he gained a sufficient sum to enable him to leave his master, and to continue at Rome writing for the stage. Of the rest of his life nothing is known. It is even doubtful whether he ever obtained the Roman franchise. The date of his death is differently stated by St Jerome and by Cicero. The former (*Chronicles of Eusebius*) names as the time of his death the 145th Olympiad,—that is, between the years 200 and 196 B.C.; while the latter (Brutus, 15), who is more exact, informs us that he died in the consulship of P. Claudius and L. Porcius, while Cato was censor,—that is, 183 B.C. Thus we find that he flourished during the second Punic war, and was contemporary with Cato.

It is difficult, if not impossible, to ascertain how many comedies Plautus actually wrote. Even in the time of Varro, as we see by the chapter in Aulus Gellius already quoted, it was a matter of dispute. Varro, it seems, wrote a book on the subject, entitled *Quæstiones Plautinæ.* At that time no less than 130 plays claimed Plautus as their author. Of these, Varro chose out 21 as being undoubtedly authentic, which, from this circumstance, were called Varronianæ. Among these were the 20 now extant, the *Vidularia*, which is lost, being the 21st. Varro, however, considered others besides these the work of Plautus; and L. Ælius fixes the number at 25. According to Gellius, several plays, which bore the names of other writers, had internal evidence of their having been written by Plautus (*Plautinissimi*). Such were the *Bœotia*, the *Nervolaria*, and the *Fretum*. The remaining plays attributed to Plautus are accounted for in two ways; either there was another comic poet of the name of Plautius, whose works (*Plautianæ*) were confounded with those of Plautus (*Plautinæ*), from the similarity of the two words; or they were the work of contemporaries, which were retouched (*retractatæ et expolitæ*) by Plautus. Probably both conjectures are true.

It is supposed that the extant comedies were arranged in their present order by Priscian the grammarian, who is also thought to have written the acrostic argument prefixed to each. The comedies follow one another, with one exception, in the alphabetical order:—1. The *Amphitryon* is the history of the birth of Hercules, in which his father Jupiter appears in a very questionable light. This play, in its ridicule of the gods, approaches the old Greek comedy more nearly than any of the other productions of Plautus. He himself called it a tragic comedy. So popular was it among the Romans that, as Arnobius tells us, it continued to be acted at Rome in the reign of Diocletian. The *Amphitryon* of Molière, and the *Two Socias* of Dryden, are both imitations of this play. 2. The *Asinaria* is a translation of a comedy written, according to Lessing, by Diphilus, a Greek comic poet. It is the story of a father and son in love with the same mistress. It contains much that is amusing, together with a great deal that is obscene. 3. The *Aulularia* is the story of a miser who discovers in his house a hidden treasure. Unfortunately the end of this play is lost. From the acrostic argument of Priscian, however, Antonius Codrus Urceus, a professor at Bologna, has attempted to supply the deficiency. On it Molière has founded his *Avare;* and Shadwell and Fielding their *Miser.* 4. The *Captivi* is generally acknowledged to be the masterpiece of Plautus. For it Lessing has an unbounded admiration, and even pronounces it "the best piece which has ever come upon the stage." He tells us that, though he had repeatedly read it, with a view to discovering some fault, far from doing so, on each perusal he had found more reason to admire it. It has an excellent plot, abounds with humour, and, far from having any taint of ribaldry, has a decidedly moral tendency. 5. The *Curculio.* 6. The *Casina*, copied from the Greek of Diphilus, is not a play of much merit. The prologue was evidently written long after its first representation, and after the death of Plautus. 7. The *Cistellaria* is a short piece, containing much that is obscene, and little that is interesting. 8. The *Epidicus*, a good play, was a great favourite with Plautus himself. 9. The *Bacchides*, a most ribald farce, is the only case in which the alphabetical arrangement of the plays is not kept. This is accounted for by the fact that, in the 215th line, the *Epidicus* is mentioned, thereby proving that it was written before the *Bacchides.* 10. The *Mostellaria* has been imitated by Reynard in his *Unexpected Return*, and also by Fielding in his *Intriguing Chambermaid.* 11. The *Menœchmi* is very clever and amusing. It has been imitated by Shakspeare in his *Comedy of Errors*, and by Reynard. 12. The *Miles Gloriosus* is one of the best dramas of Plautus. The subject is the outwitting of a braggart. 13. The *Mercator*, a play of small merit, is founded upon the 'Εμπορὸς of Philemon. 14. The *Pseudolus.* This play, and the *Truculentus*, we are told by Cicero (*De Senectute*), were considered by Plautus himself as his two best. The *Pseudolus* certainly is very good; but of the *Truculentus* we cannot say so much. In our opinion, it is the very worst of all the plays, being deficient in plot and filled with obscenity. 15. The *Pœnulus* is remarkable for containing some Carthaginian words, almost the only relics of that language. 16. The *Persa.* 17. The *Rudens*, a pleasing play, but with an unsatisfactory conclusion. 18. The *Stichus.* 19. The *Trinummus* is considered by Lessing to be the best production of its author, next to the *Captivi.* 20. *Truculentus.* 21. *Vidularia.* This play is supposed to have followed the *Truculentus*, and completed the 21 Varronianæ, from the fact, that in an old manuscript (*Codex* of Camerarius), at the end of the *Truculentus*, are the words "Incipit Vidularia," and that at the end of the palimpsest manuscript there are a few sentences of this play.

Horace, in his *Ars Poetica* (270), has the following severe criticism upon Plautus:—

> "At vestri proavi Plautinos et numeros et
> Laudavere sales, nimium patienter utrumque
> Ne dicam stulte, mirati, si modo ego et vos
> Scimus inurbanum lepido seponere dicto,
> Legitimumque sonum digitis callemis et aure."

Lessing has tried to prove that Horace does not mean by these words the unqualified condemnation of Plautus which they seem to imply at first sight, but that he merely condemns his verses. However this may be, we cannot wonder that the polished ear of Horace should have been offended by some of the coarse jokes and irregular lines of Plautus. But, at the same time, Horace ought to have remembered that 150 years had passed since Plautus flourished, and that taste and feeling had much changed in the interval. Such was not, however, the universal opinion of the learned men of the Augustan age. For Cicero (*De Officiis*, 29) says:—"Comedy is of two very different kinds,—the one illiberal, quarrelsome, shameless, and obscene; the other of great elegance, refinement, genius, and wit; to which latter class belong not only our Plautus and the ancient comedy of the Athenians, but also the books of the Socratic philosophers;" thus placing Plautus on a level with the Athenian philosophers and the writers of the Old Comedy. Quintilian (x. 1) also tells us that L. Ælius Stilo used to have so great an admiration for the works of Plautus as to say that, "If the Muses were to speak Latin, they would adopt the language of Plautus."

If the wit of Plautus sometimes seems to us insipid, and his jokes coarse, we must keep in mind how entirely the force of comedy depends upon the circumstances and manners of the age in which it is produced. As Plautus wrote exclusively for the stage, to gain the applause of the lower classes, he was obliged to have recourse to that low buffoonery which was most attractive to them. Sometimes, indeed, Plautus may have intended, by exposing, to check the immoralities of his day. But if such were his object, he ought not throughout to have made the courtezan the only female who had any attractions in the way of wit or conversation, while the lawful wife is generally a mute or else an intolerable scold, who is to be ridiculed and outwitted. Deducting, however, from Plautus all that is low and disgusting, there still remains a fund of real humour for which no one can refuse him admiration. The comedies of Plautus belong to the Comœdia Palliata. His works, and those of Terence, are indeed the only means we have of judging of the New Comedy of the Greeks. For the writings of Menander, Diphilus, Philemon, and the other writers of the New Comedy are, with the exception of a few stray sentences, entirely lost. From this fact, we are unable to ascertain how far they were actually copied by Plautus; but from the Roman tone which pervades his characters, their actions, and their jokes, no one can for a moment suppose that he was a servile copyist. Terence probably imitated his Greek models far more exactly than Plautus; for though Terence is certainly the more elegant and refined writer, Plautus is by far the more original and truly Roman. The comedies of Plautus are not perhaps so interesting to us as those of Aristophanes and the writers of the Old Comedy. For Aristophanes rakes up for us the skeleton closets, and shows us the weak points of those ancients whom we worship almost as demigods; whereas the New Comedy is only a transition between the old and that of modern times, without the piquancy belonging to personality, and with none of the polish and fine discrimination of character which marks the comedy of our days. The text of Plautus is very corrupt. Much of the original has been lost, and the text has been filled with interpolations. This is principally owing to all the manuscripts which we had having been copied from one which was itself corrupt. Some years ago, however, there was discovered in the Ambrosian Library at Milan the palimpsest manuscript, which is as old as the fifth century. This is much purer, though even in it are found some interpolations. Ritschl has already produced six of the plays, with their text, founded on this manuscript.

The oldest edition of the entire works of Plautus which we have is that of Georgius Merula, which was produced at Venice in the year 1472. The best of the earlier editions are those of Taubman, Frankfort, 1605; Wittenburg, 1612 and 1621; Grovonius, Leyden, 1664 and 1669; and at Amsterdam, 1684, the text of which was got by the comparison of six different manuscripts. The best modern editions of the entire works are those of Bothe, Berlin, 1809; and, last, at Leipsic, 1834; and of Weise, Quedlinburg, 1837–38. Ritschl's edition, when completed, will surpass all those previous to it.

The best books we have on Plautus are Lessing's Essay *Von dem Leben und den Werken des Plautus*, to which we are deeply indebted; and Ritschl's *Parergon Plautinorum Terentianorumque.*

Plautus has been translated into almost every European language. The best English translation is that of Bonell Thornton, vols. i. ii. (1767); and Richard Warner, vols. iii. iv. (1773), into familiar blank verse. (C. H. C.)

PLAYFAIR, John, a mathematician and philosopher of great eminence and celebrity, and so peculiarly a benefactor to this publication, as would have made it fit that some memorial of him should be preserved in these pages, even if it could have been surmised that it might not have been found in any other place. There are few names, however, in the recent history of British science that are more extensively or advantageously known, or of which the few particulars that remain to be recorded will be more generally interesting. His life, like most others that have been dedicated to the silent pursuits of learning and science, does not abound in incidents or adventures; but it is full of honour, both for the individual and the studies to which he was devoted, and may be read with more profit than many more ambitious histories.

He was the eldest son of the Reverend James Playfair, minister of Benvie in Forfarshire, in which place he was born on the 10th of March 1748. He resided at home, under the domestic tuition of his father, until the age of fourteen, when he entered at the university of St Andrews; and was almost immediately distinguished not merely for his singular proficiency in mathematical learning, but for the extent of his general knowledge, the clearness of his judgment, and the dignity and propriety of his conduct. A remarkable testimony to this effect has been made public in an early letter of Principal George Hill, who was at this time one of his fellow-students, and was himself so remarkable for early talent that we find it recorded of him that he had privately composed an excellent sermon in the tenth year of his age. A youth of this description cannot be supposed to have been very indulgent in his estimate of the merits of his competitors; and it could therefore have been no ordinary measure of ability that called forth the following ingenuous avowal, in a confidential letter to his mother: "Playfair has very great merit, and more knowledge and a better judgment than any of his class-fellows. I make *no* exceptions; my parts might be more showy, and the kind of reading to which my inclination led me was calculated to enable me to make a better figure at St Andrews; but in judgment and understanding I was greatly inferior to him." (Dr Cook's *Life of Principal Hill.*) It is scarcely a stronger, though undoubtedly a very different proof of his rare attainments, that when the professor of natural philosophy, Wilkie, the once celebrated author of the *Epigoniad*, was prevented by indisposition from delivering the regular lectures, he used generally to delegate the task of instruction to his youthful pupil. Wilkie, besides being a scholar and philosopher of no mean note, was a man of primitive benevolence and integrity, and of great vivacity in conversation; and the friendship which, in spite of the disparity of their years, was speedily formed between him and young Playfair, speaks as much for the social and moral character of the latter, as his substitution of him in the class-room does for his early proficiency in science. On this last subject we shall mention but one fact more. In 1766, when only eighteen years of age, he offered himself, with the approbation of his instructors at St Andrews, as candidate for the professorship of mathematics in Marischal College, Aberdeen, and sustained, with the most distinguished credit, an examination or comparative trial which lasted eleven days, and embraced nearly the whole range of the exact sciences. Out of the six competitors who entered the lists against him, two only were judged to have excelled him, the Reverend Dr Trail, who was appointed to the office, and Dr Hamilton, who afterwards succeeded to and long filled it with much reputation.

In 1769 he removed to Edinburgh, where his merit and modesty very soon introduced him to the friendship of Dr Robertson, Adam Smith, Dr Matthew Stewart, Dr Black, and Dr Hutton; with all of whom he continued on terms of the utmost cordiality during the whole period of their lives. In 1772 he was a candidate for the professorship of natural philosophy at St Andrews, vacant by the death of his friend Dr Wilkie. There was no comparative trial on this occasion; and he was again unsuccessful, under circumstances which have led one of the most dutiful sons of that university (Dr Cook, in his *Life of Principal Hill*) to remark "how much it suffered in thus losing a man by whose talents its reputation would have been so highly promoted." In the course of the same year, the death of his father suddenly devolved upon him the burden of supporting the family, and admonished him no longer to delay the final election of a profession. He had been educated with a view to the church, and was every way qualified to accept a living on the Establishment; but his decided predilection for science had hitherto made him hesitate about engaging in a vocation, the duties of which, he felt, if conscientiously discharged, would necessarily interfere to a great extent with the studies he was loath to abandon. In this emergency, however, he thought himself no longer entitled to indulge in those predilections, and accordingly made application to Lord Gray, the patron, for a presentation to the livings of Liff and Benvie, which had been filled by his father. His lordship was too well aware of his merits to hesitate about conferring so great a benefit on his parishioners; and immediately issued a presentation in his favour, although, from some challenge of his right to the patronage, induction was not obtained until late in the year 1773.

From this period until 1782 Playfair was constantly resident at Liff, and occupied almost exclusively with the pastoral duties of his office. In this retreat his leisure hours were dedicated to the education of his younger brothers, and to a very close and intimate correspondence with Robertson (afterwards Lord Robertson), the son of the illustrious historian, to whom he seems to have confined the remarks that occurred to him upon the different authors he perused, and the subjects of speculation which they suggested. We cannot help hoping that some selection from this correspondence may one day be given to the public. In the year 1779 he contributed to the *Transactions of the Royal Society of London* a paper on the "Arithmetic of Impossible Quantities," which exhibits, within a very small compass, a striking example of the rare and admirable talent of detaching the sound spirit of science from what may be termed its mysticism, and circumscribing, by the most precise and luminous boundaries, the vague and unlimited inquiries into which many mathematicians had been seduced by the nature of the instruments they employed.

In the year 1782 he was induced, by very advantageous offers, to resign his charge, and to superintend the education of Ferguson of Raith, and his brother Sir Ronald; an arrangement which restored him in a great measure to the literary and scientific society of Edinburgh, and enabled him to gratify himself by a personal introduction to several of the most eminent cultivators of science in London. He had repeatedly visited Dr Maskelyne, astronomer-royal, whilst that ingenious mathematician was busied, in 1774, in making a series of observations in Perthshire on the attraction of mountains; and, whilst sharing the shelter of his tent on the side of Schehallien, contracted with him a cordial friendship, which continued unbroken for the remainder of their lives. Under these honourable auspices he made his first appearance in London in 1782, and was speedily introduced to all those in whom he was likely to take most interest. He seems to have kept a pretty full and correct journal of all that he observed during this journey to the metropolis; and a portion of it, which is prefixed to the late collection of his works, is, in our judgment, one of the most interesting parts of that publication. It is not only written with great elegance and accuracy, but affords, in the free, candid, and pointed observations which it contains on the different individuals with whom he comes in contact, a very remarkable proof of his quick and sagacious perception of character, and his power of selecting and turning to account, even in the fever and distraction of a first visit to such a scene, all that was really worthy of careful observation or permanent remembrance.

In 1785 he was received into the university of Edinburgh, in consequence of an arrangement between his two illustrious associates, Dr Adam Ferguson and Mr Dugald Stewart. Mr Stewart exchanged the chair of mathematics, in which he had succeeded to his father, for that of moral philosophy, which had been long filled by Dr Ferguson, who, finding that the delicate state of his health would prevent him from discharging the active duties of the mathematical professor, immediately devolved them upon Playfair, for whom he procured the appointment of joint professor in that department.

In 1788 he published, in the *Transactions of the Royal Society of Edinburgh*, a biographical account of Dr Matthew Stewart, which is remarkable, not only for the ease and purity of the style, but also as containing a singularly clear and interesting account of the labours of Dr Simson in the restoration of the ancient geometry, and of the success both of him and Dr Stewart in adapting the elegant simplicity of the Greek methods of investigation to problems which had previously been regarded as insoluble except by the aid of the modern analysis. He also published, in the same year, a paper "On the Causes which affect the Accuracy of Barometrical Measurements," which is written with all the perspicuity, caution, and sagacity that constitute the great excellence and the great difficulty of such disquisitions, where scientific principles are employed to give precision to physical observations.

In 1790 he published in the same *Transactions* a paper of still greater interest and delicacy, "On the Astronomy of the Brahmins,"—a subject which had been recently recommended to the notice of the European scientific world by the curious and learned observations of M. Bailly, in his *General History of Astronomy*, but had never met with so minute and scrupulous an investigation as it now received at the hands of Mr Playfair. The whole treatise is written with a beautiful perspicuity, in an admirable spirit of candour and ingenuity, and in a style more elegant and spirited than had yet lent its attraction to subjects so recondite and abstruse. The publication accordingly attracted very general notice, both in Europe and in Asia; and gave rise to much discussion and research, the final value and result of which does not seem yet to be ascertained. This was followed in 1794 by a learned and very beautiful treatise on the *Origin and Investigation of Porisms*, in which the obscure nature of the very comprehensive and indefinite theorems to which this name was applied by the ancient geometers, is explained with the most lucid simplicity; and the extraordinary merits of Dr Simson, in deducing their true theory from the very vague and scanty notices of them which had come down to his time, are commemorated with a noble spirit of emulation.

In 1795 he published his *Elements of Geometry*, for the use of the pupils attending his class,—a work which has since been held in such estimation by the public as to have gone through numerous editions of a thousand copies each. In 1797 he composed a sequel to his first paper on the Indian Astronomy, in the shape of *Observations on the Trigonometrical Tables of the Brahmins;* and also a masterly collection of *Theorems on the Figure of the Earth.* It is also understood that he occupied himself a good deal at this time in the preparation of an *Essay on the Accidental Discoveries made by Men of Science while in Pursuit of some other Object*, although we find no portion of this curious discussion in the collection of his works.

His excellent and ingenious friend Dr Hutton died in the year last mentioned; and Playfair, having undertaken to draw up a biographical account of him for the Royal Society, was first led to study his ingenious but somewhat crude speculations on the *Theory of the Earth*, and afterwards to lend them the assistance of his own powerful pen in his *Illustrations of the Huttonian Theory.* This work, upon which he bestowed more time and labour than on any of his other productions, did not appear till 1802; and it was not till 1803 that he presented to their associates his admirable memoir of their departed friend.

Whatever opinion may be formed, now or hereafter, of the truth or soundness of the suppositions by which Dr Hutton endeavoured to explain the actual state and condition of our globe, it is impossible to doubt that Playfair's illustration of that theory must always be ranked amongst the most brilliant aad powerful productions of philosophical genius. The beautiful clearness and captivating eloquence with which the system itself is unfolded and explained, the spirit and force of reasoning with which all the objections to it are combated, the skill with which the infinite variety of facts which it brought into view are combined into one grand and legitimate introduction, and the judgment and extent of learning by which so many large and profound views of nature are brought to bear upon the points in discussion, and blended into one large and discursive argument, uniting the utmost logical precision with the richest variety of topics and the highest graces of composition,—are merits which have been universally acknowledged in this performance, even by those who have not been convinced by its reasonings; and have extorted, even from the fastidious critics of France, the acknowledgment that "Mr Playfair writes as well as Buffon, and reasons incomparably better."

The biographical account of Dr Hutton is by far the best of Playfair's productions in this line, and contains not only an eloquent and luminous account of the speculations in which he was engaged, but, what is too often forgotten in this species of biography, a charming portrait of the individual, drawn, no doubt, by a favourable hand, but gaining far more in grace and effect than it can possibly have lost in correctness, from the softening colours of affection.

In 1805 he quitted the chair of mathematics to succeed Professor Robison in that of natural philosophy. The appointment of Leslie as his successor in the chair of mathematics was opposed at the time by a majority of the Presbytery of Edinburgh, and made the subject of very angry discussion, as well in various publications as in the General Assembly of the Church of Scotland. From both these fields of contention the opponents of Leslie retired discomfited, and, in the opinion, we believe, of many of the lookers on, disgraced. Amongst the heaviest blows they had to sustain were those that parted from the hand of Mr Playfair. He first addressed a Letter to the Lord Provost, in which, after asserting, with infinite spirit and freedom, the dignity of the science in question, he openly imputes the new-sprung zeal for orthodoxy, which had prompted the attack on Leslie, to a wish or design on the part of some of the clergymen of Edinburgh to obtain for themselves a number of the chairs in that university, which had hitherto afforded sufficient occupation to the undistracted industry of laymen. And when this denunciation brought upon him a series of acrimonious and unhandsome attacks, he replied to them all in a pamphlet of greater bulk, written in a style of which the high polish and elegance only serve to give a keener edge to the unsparing severity of the exposures which it conveys.[1] We do not know, indeed, where to find a more perfect model of polemical or controversial writing; and much as it was to be regretted that an occasion should have arisen for employing such a pen and such a mind as Playfair's on any temporary or personal theme, it is impossible not to admire the extraordinary talent and vigour with which, when the occasion did arrive, he could turn talents, exercised in far other studies, to the purposes suggested by the emergency.

In 1807 he was elected a fellow of the Royal Society of London, and soon afterwards presented to that learned body his *Lithological Survey of Schehallien.* In 1809 he contributed to the *Edinburgh Transactions* an excellent paper on "Solids of the greatest Attraction," and in 1812 another on the "Progress of Heat in Spherical Bodies."

In 1814 he published, in 2 vols. 8vo, for the use of his class, an elementary work of great value, under the title of *Outlines of Natural Philosophy.* For some years before this, he had been much occupied in digesting the plan and collecting the materials for a greatly enlarged edition of his *Illustrations of the Huttonian Theory;* with a view to which, he had not only carefully perused and extracted a vast body of voyages and travels, but had made various journeys, and very minutely examined almost all the places in the British dominions the structure of which promised to throw any light on the subject of his researches. No part of the work, however, was actually written, when the preparation for it was suspended by his being induced to draw up for this publication an introductory *Dissertation on the Progress of Mathematical and Physical Science;* a treatise which, though its author had written nothing else, would itself suffice to carry down his name with distinction to the latest posterity. The soundness of judgment, the beauty of the writing, the extent of knowledge, the candour and precision of the estimates of character, and the noble spirit of liberality and generous admiration for genius which breathes throughout the whole performance, give it an attraction which is rarely to be found in works of the same erudition, and render it not only one of the most instructive, but one of the most interesting publications that philosophy has ever bestowed on the world.

---

[1] This piece is entitled *Letter to the Author of the Examination of Mr Stewart's Short Statement of Facts relative to the Election of Professor Leslie*, 8vo, Edin. 1806. It has not been reprinted in the collection of his works.

In 1815 he drew up for the Royal Society of Edinburgh a very interesting memoir of his distinguished predecessor Dr John Robison, a philosopher in whose early life there was more adventure, and in his later days more political prejudice, than we usually find to diversify the history of men of science. Nothing can be more spirited and interesting than Playfair's account of the former; nothing more manly and tender than his reluctant but decided protestation against the excesses of the latter.

After the general peace in 1815 had at last opened the Continent to British inquirers, Playfair, at the age of sixty-eight, undertook a long journey through France and Switzerland into Italy, and did not return for a period of nearly eighteen months. His principal attention was directed to the mineralogical and geological phenomena of the different regions which he visited; and he made many notes with a view to the great object which he was not destined to accomplish, namely,—the extension and new-modelling of his *Illustrations of the Huttonian Theory.* Every object of liberal curiosity, however, had for him an attraction as fresh as in his earliest youth; and the social simplicity and benevolence of his character and manners insured him a favourable reception in every new society to which he was introduced.

On his return from this expedition, he employed himself chiefly in preparing the second part of the Dissertation to which we have alluded; and he also drew up a Memoir on the Naval Tactics of Clerk of Eldin, which was published after his death in the *Philosophical Transactions*, though only a fragment of a projected life of Clerk, which he did not live to complete. His health had been occasionally broken for several years by the recurrence of a painful affection of the bladder, which appeared with increased severity in the early part of 1819, but was so far got under as to enable him to complete his course of lectures in the spring. It returned, however, in a still more distressing form in the summer, and at last put a period to his life on the 19th of July. Though suffering great pain during the last part of his confinement, he retained not only his intellectual faculties quite unimpaired, but also the serenity and mildness of his spirit, and occupied himself till within a few days of his death in correcting the proof-sheets of the Dissertation, the printing of the second part of which had commenced some time before his last illness.[1]

Before concluding these notices of Playfair's scientific and literary labours, we have still to mention that, from the year 1804, he was a frequent contributor to the *Edinburgh Review;* and that though most of his articles were of a scientific description, he occasionally diverged into the field of general literature, or indulged in the refinements of metaphysical speculation. Many of his scientific articles attracted great attention on the Continent as well as at home; and several of them are written with a force and beauty that might well entitle them to a higher place than the pages of a periodical publication. There is no general account of the great facts and principles of astronomy so clear, and comprehensive, and exact, nor half so beautiful or majestic in the writing, as his account of Laplace's *Mécanique Céleste*, in the eleventh volume of the publication just mentioned.

In this brief sketch of the events of Playfair's life we have purposely omitted any general account, either of his personal character, or of the distinguishing features of his intellectual powers and habits, thinking it better to give those by themselves, in the words in which they were recorded, to the satisfaction, we believe, of most of those who knew him intimately, in a periodical journal wherein they appeared a short time after his death. The portrait there given has been pronounced by one of the earliest and most illustrious of his surviving friends, "a faithful and perfect resemblance;"[2] and has accordingly been allowed a place in the prefatory memoir which his nephew has prefixed to the collection of his works.

"It has struck many people, we believe, as very extraordinary that so eminent a person as Playfair should have been allowed to sink into his grave in the midst of us, without calling forth almost so much as an attempt to commemorate his merit, even in a common newspaper; and that the death of a man so celebrated and so beloved, and at the same time so closely connected with many who could well appreciate and suitably describe his excellences, should be left to the brief and ordinary notice of the daily obituary. No event of the kind certainly ever excited more general sympathy; and no individual, we are persuaded, will be longer or more affectionately remembered by all the classes of his fellow-citizens; and yet it is to these very circumstances that we must look for an explanation of the apparent neglect by which his memory has been followed. His humbler admirers have been deterred from expressing their sentiments by a natural feeling of unwillingness to encroach on the privilege of those whom a nearer approach to his person and talents rendered it more worthy to speak of them; whilst the learned and eloquent amongst his friends have trusted to each other for the performance of a task which they could not but feel to be painful in itself, and not a little difficult to perform as it ought to be; or perhaps have reserved for some more solemn occasion that tribute for which the public impatience is already at its height.

"We beg leave to assure our readers that it is merely from anxiety to do *something* to gratify this natural impatience that we presume to enter at all upon a subject to which we are perfectly aware that we are incapable of doing justice; for of Mr Playfair's scientific attainments, of his proficiency in those studies to which he was peculiarly devoted, we are but slenderly qualified to judge. But we believe we hazard nothing in saying that he was one of the most learned mathematicians of his age, and among the first, if not the very first, who introduced the beautiful discoveries of the later continental geometers to the knowledge of his countrymen, and gave their just value and true place, in the scheme of European knowledge, to those important improvements by which the whole aspect of the abstract sciences has been renovated since the days of our illustrious Newton. If he did not signalize himself by any brilliant or original invention, he must at least be allowed to have been a most generous and intelligent judge of the achievements of others, as well as the most eloquent expounder of that great and magnificent system of knowledge which has been gradually evolved by the successive labours of so many gifted individuals. He possessed, indeed, in the highest degree, all the characteristics both of a fine and a powerful understanding,—at once penetrating and vigilant, but more distinguished perhaps for the caution and sureness of its march, than for the brilliancy or rapidity of its movements; and guided and adorned through all its progress by the most genuine enthusiasm for all that is grand, and the justest taste for all that is beautiful, in the truth or the intellectual energy with which he was habitually conversant.

---

[1] Besides the Dissertation, Mr Playfair contributed the valuable biographical account of ÆPINUS, and the still more valuable articl on PHYSICAL ASTRONOMY.

[2] Letter from Mr Dugald Stewart to Dr Playfair, in the Appendix to the Biographical Account of Professor Playfair, prefixed to the collection of his works, published at Edinburgh in 1822, in 4 vols. 8vo.

"To what account these rare qualities might have been turned, and what more brilliant or lasting fruits they might have produced, if his whole life had been dedicated to the solitary cultivation of science, it is not for us to conjecture; but it cannot be doubted that they added incalculably to his eminence and utility as a teacher, both by enabling him to direct his pupils to the most simple and luminous methods of inquiry, and to imbue their minds, from the very commencement of the study, with that fine relish for the truths it disclosed, and that high sense of the majesty with which they were invested, that predominated in his own bosom. Whilst he left nothing unexplained or unreduced to its proper place in the system, he took care that they should never be perplexed by petty difficulties, or bewildered in useless details, and formed them betimes to that clear, masculine, and direct method of investigation by which, with the least labour, the greatest advances might be accomplished.

"Mr Playfair, however, was not merely a teacher; and has fortunately left behind him a variety of works, from which other generations may be enabled to judge of some of those qualifications which so powerfully recommended and endeared him to his contemporaries. It is perhaps to be regretted that so much of his time, and so large a proportion of his publications, should have been devoted to the subjects of the Indian astronomy, and the Huttonian theory of the earth. For though nothing can be more beautiful or instructive than his speculations on those curious topics, it cannot be dissembled that their results are less conclusive and satisfactory than might have been desired; and that his doctrines, from the very nature of the subjects, are more questionable than we believe they could possibly have been on any other topic in the whole circle of the sciences. To the first, indeed, he came under the great disadvantage of being unacquainted with the eastern tongues, and without the means of judging of the authenticity of the documents which he was obliged to assume as the elements of his reasonings; and as to the other, though he ended, we believe, with being a very able and skilful mineralogist, we think it is now generally admitted that that science does not yet afford sufficient materials for any positive conclusion, and that all attempts to establish a theory of the earth must, for many years to come, be regarded as premature. Though it is impossible, therefore, to think too highly of the ingenuity, the vigour, and the eloquence of those publications, we are of opinion that a juster estimate of Mr Playfair's talent, and a truer picture of his genius and understanding, is to be found in his other writings—in the papers, both biographical and scientific, with which he has enriched the *Transactions* of our Royal Society; his account of Laplace, and other articles, which he is understood to have contributed to the *Edinburgh Review;* the Outlines of his Lectures on Natural Philosophy; and, above all, his Introductory Discourse to the Supplement to the Encyclopædia Britannica, with the final correction of which he was occupied up to the last moments that the progress of his disease allowed him to dedicate to any intellectual exertion.

"With reference to these works, we do not think we are influenced by any national or other partiality when we say that he was certainly one of the best writers of his age; and even that we do not now recollect any one of his contemporaries who was so great a master of composition. There is a certain mellowness and richness about his style which adorns without disguising the weight and nervousness, which is its other great characteristic,—a sedate gracefulness and manly simplicity in the more level passages, and a mild majesty and considerate enthusiasm where he rises above them, of which we scarcely know where to find any other example. There is great equability, too, and sustained force, in every part of his writings. He never exhausts himself in flashes and epigrams, nor languishes into tameness and insipidity; at first sight you would say that plainness and good sense were the predominating qualities, but by and by this simplicity is enriched with the delicate and vivid colours of a fine imagination, the free and forcible touches of a most powerful intellect, and the lights and shades of an unerring and harmonizing taste. In comparing it with the styles of his most celebrated contemporaries, we would say that it was more purely and peculiarly a *written* style, and therefore rejected those ornaments that more properly belong to oratory. It had no impetuosity, hurry, or vehemence,—no bursts or sudden turns or abruptions like that of Burke; and though eminently smooth and melodious, it was not modulated to a uniform system of solemn declamation like that of Johnson; nor spread out in the richer and more voluminous elocution of Stewart; nor still less broken into that patchwork of scholastic pedantry and conversational smartness which has found its admirers in Gibbon. It is a style, in short, of great freedom, force, and beauty; but the deliberate style of a man of thought and of learning, and neither that of a wit throwing out his extempores with an affectation of careless grace, nor of a rhetorician thinking more of his manner than his matter, and determined to be admired for his expression, whatever may be the fate of his sentiments.

"His habits of composition, as we have understood, were not perhaps exactly what might have been expected from their results. He wrote rather slowly, and his first sketches were often very slight and imperfect, like the rude chalking for a masterly picture. His chief effort and greatest pleasure was in their revisal and correction; and there were no limits to the improvement which resulted from this application. It was not the style merely, or indeed chiefly, that gained by it,—the whole reasoning, and sentiment, and illustration were enlarged and new-modelled in the course of it, and a naked outline became gradually informed with life, colour, and expression. It was not at all like the common finishing and polishing to which careful authors generally subject the first draught of their compositions, nor even like the fastidious and tentative alterations with which some more anxious writers assay their choicer passages. It was, in fact, the great filling in of the picture, the working up of the figured *weft* on the naked and meagre *woof* that had been stretched to receive it; and the singular thing in his case was, not only that he left this most material part of his work to be performed after the whole outline had been finished, but that he could proceed with it to an indefinite extent, and enrich and improve as long as he thought fit, without any risk either of destroying the proportions of that outline, or injuring the harmony and unity of the design. He was perfectly aware, too, of the possession of this extraordinary power; and it was partly, we presume, in consequence of this consciousness that he was not only at all times ready to go on with any work in which he was engaged, without waiting for favourable moments or hours of greater alacrity, but that he never felt any of those doubts and misgivings as to his being able to get creditably through with his undertaking to which we believe most authors are occasionally liable. As he never wrote upon any subject of which he was not perfectly master, he was secure against all blunders in the substance of what he had to say; and felt quite assured that, if he was only allowed time enough, he should finally come to say it in the very best way of which he was capable. He had no anxiety, therefore, either in undertaking or proceeding with his task, and intermitted and resumed them at his convenience, with the comfortable certainty that all the time he bestowed on them was turned to good account, and that what was left imperfect at one sitting might be finished with equal ease and advantage at another. Being thus perfectly sure both of his end and his means, he experienced, in the course of his compositions, none of that little fever of the spirits with which that operation is so apt to be accompanied. He had no capricious visitings of fancy, which it was necessary to fix upon the spot or to lose for ever; no casual inspiration to invoke and to wait for; no transitory and evanescent lights to catch before they faded. All that was in his mind was subject to his control, and amenable to his call, though it might not obey at the moment; and whilst his taste was so sure that he was in no danger of overworking anything that he had designed, all his thoughts and sentiments had that unity and congruity that they fell almost spontaneously into harmony and order; and the last added, incorporated, and assimilated with the first, as if they had sprung simultaneously from the same happy conception.

"But we need dwell no longer on qualities that may be gathered hereafter from the works he has left behind him. They who lived with him mourn the most for those which will be traced in no such memorial; and prize far above those talents which gained him his high name in philosophy, that personal character which endeared him to his friends, and shed a grace and a dignity over all the society in which he moved. The same admirable taste which is conspicuous in his writings, or rather the higher principles from which that taste was but an emanation, spread a similar charm over his whole life and conversation, and gave to the most learned philosopher of his day the manners and deportment of the most perfect gentleman. Nor was this in him the result merely of good sense and good temper, assisted by an early familiarity with good company, and a consequent knowledge of his own place and that of all around him. His good breeding was of a higher descent; and his powers of pleasing rested on something better than mere companionable qualities. With the greatest kindness and generosity of nature he united the most manly firmness and the highest principles of honour, and the most cheerful and social dispositions with the gentlest and steadiest affections. Towards women he had always the most chivalrous feelings of regard and attention, and was, beyond almost all men, acceptable and agreeable in their society, though without the least levity or pretension unbecoming his age or condition; and such, indeed, was the fascination of the perfect simplicity and mildness of his manners, that the same tone and deportment seemed equally appropriate in all societies, and enabled him to delight the young and the gay with the same sort of conversation which instructed the learned and the grave. There never, indeed, was a man of learning and talent who appeared in society so perfectly free from all sorts of pretension or notion of his own importance, or so little solicitous to distinguish himself, or so sincerely willing to give place to every one else. Even upon subjects which he had thoroughly studied he was never in the least impatient to speak, and spoke at all times without any tone of authority; whilst, so far from wishing to set off what he had to say by any brilliancy or emphasis of expression, it seemed generally as if he had studied to disguise the weight and originality of his thoughts under the plainest form of speech and the most quiet and indifferent manner; so that the profoundest remarks and subtlest observations were often dropped, not only without any solicitude that their value should be observed, but without any apparent consciousness that they possessed any. Though the most social of human beings, and the most disposed to encourage and sympathise with the gaiety and joviality of others, his own spirits were in general rather cheerful than gay, or at least never rose to any turbulence or tumult of merriment; and whilst he would listen with the kindest indulgence to the more extravagant sallies of his younger friends, and prompt them by the heartiest approbation, his own satisfaction might generally be traced in a slow and temperate smile, gradually mantling over his benevolent and intelligent features, and lighting up the countenance of the sage with the expression of the mildest and most genuine philanthropy. It was wonderful, indeed, considering the measure of his own intellect, and the rigid and undeviating propriety of his own conduct, how tolerant he was of the defects and errors of other men. He was too indulgent, in truth, and favourable to his friends, and made a kind and liberal allowance for the faults of all mankind; except only faults of baseness or of cruelty, against which he never failed to manifest the most open scorn and detestation. Independently, in short, of his high attainments, Mr Playfair was one of the most amiable and estimable of men: delightful in his manners, inflexible in his principles, and generous in his affections, he had all that could charm in society or attach in private; and whilst his friends enjoyed the free and unstudied conversation of an easy and intelligent associate, they had at all times the proud and inward assurance that he was a being upon whose perfect honour and generosity they might rely with the most implicit confidence, in life and in death,—and of whom it was equally impossible that, under any circumstances, he should ever perform a mean, a selfish, or a *questionable* action, as that his body should cease to gravitate or his soul to live.

"If we do not greatly deceive ourselves, there is nothing here of exaggeration or partial feeling, and nothing with which an indifferent and honest chronicler would not concur. Nor is it altogether idle to have dwelt so long on the personal character of this distinguished individual. For we are ourselves persuaded that this personal character has done almost as much for the cause of science and philosophy amongst us as the great talents and attainments with which it was combined; and has contributed in a very eminent degree to give to the better society of Edinburgh that tone of intelligence and liberality by which it is so honourably distinguished. It is not a little advantageous to philosophy that it is in fashion; and it is still more advantageous, perhaps, to the society which is led to confer on it this apparently trivial distinction. It is a great thing for the country at large,—for its happiness, its prosperity, and its renown,—that the upper and influencing part of its population should be made familiar, even in its untasked and social hours, with sound and liberal information, and be taught to know and respect those who have distinguished themselves for great intellectual attainments. Nor is it, after all, a slight or despicable reward for a man of genius to be received with honour in the highest and most elegant society around him, and to receive in his living person that homage and applause which is too often reserved for his memory. Now, those desirable ends can never be effectually accomplished unless the manners of our leading philosophers are agreeable, and their personal habits and dispositions engaging and amiable. From the time of Hume and Robertson, we have been fortunate in Edinburgh in possessing a succession of distinguished men, who have kept up this salutary connection between the learned and the fashionable world; but there never perhaps was any one who contributed so powerfully to confirm and extend it, and that in times when it was peculiarly difficult, as the lamented individual of whom we are now speaking; and they who have had the best opportunity to observe how superior the society of Edinburgh is to that of most other places of the same size, and how much of that superiority is owing to the cordial combination of the two aristocracies of rank and of letters (of both of which it happens to be the chief provincial seat), will be best able to judge of the importance of the service he has thus rendered to its inhabitants, and, through them, and by their example, to all the rest of the country." (F. J.)

PLAYHOUSE. See THEATRE.

PLEBEIAN, or PLEBS, connected etymologically with the root PLEO, and with πλῆθος, a term applied by the more correct among the Greek writers on Roman history to the commonalty of Rome. It thus stands contrasted with *patrician;* and the two great divisions of the Roman people thus indicated give to the earliest periods of Roman history its peculiar character and interest. The ancients themselves do not agree about the time at which the distinction arose between the plebeians and the patricians. They are generally believed to have formed two distinct classes so early as the time of Romulus; while a recent writer (Dr W. Ihne's *Forschungen auf dem Gebiete der Röm. Verfassüngsgeschichte*, Frankfort, 1847) endeavours to prove that the plebeians were originally identical with the clients. The time when they first appear as a distinct class in contrast to the patricians is in the reign of Tullus Hostilius. The plebeian order, recently increased by the Alban conquest, was, in the days of Ancus Martius, far superior in point of numbers to the *populus Romanus.* They were excluded, however, from the senate, the comitia, and from all civil and priestly offices of state. In all matters connected with the army the plebeians had to shed their blood, if need were, in defence of their fellow-citizens. In judicial affairs they had to succumb to the patricians. They continued to have their own sacra; and they were free landowners, and had their own gentes.

The population of Rome thus consisted of two opposing elements. The plebeian order stood in no definite relation to the patricians; and it had no means of protecting itself against any arbitrary proceeding of the ruling class. Such a state of things could not last. Tarquinius Priscus was the first to conceive the idea of ameliorating the condition of the plebeians; but he only effected the admission of the noblest among the old plebeian families into the three old tribes. It remained for others to effect their enlargement. This was reserved for Servius Tullius. He divided the city into four parts; the plebeians into twenty-six tribes; and each plebeian received, according to Niebuhr, seven jugera of land. Each tribe had its own sacra, festivals, and meetings, which were convoked by their tribunes.

The next king that ruled over Rome the plebeians lost all they had gained. A third of the plebeians lost their estates in the war with Porsenna, became impoverished, and were perhaps for a time subject to the Etruscans. After the first secession, however, B.C. 494, the plebeians gained several great advantages. These advantages continued to progress until, in B.C. 286, Hortensius succeeded in successfully and permanently reconciling the two orders, and procuring for the *plebescita* of the plebeians the full power of *leges* binding upon the whole nation. Thus, after many generations, the government of Rome had passed from an oppressive oligarchy to a moderate democracy, in which each party had its proper influence, and the power of checking the other if it should venture to assume more than it could legally claim.

PLECTRUM (πλῆκτρον, *an instrument to strike with*), was a little stick made of various materials, such as wood, horn, ivory, and metal, with which the player struck the chords of a stringed instrument.

PLEDGE (*plegius*), in common law, a surety or gage, either real or personal, which the plaintiff or demandant is to find for his prosecuting the suit.

PLEIADES, in fabulous history, the seven daughters of Atlas, King of Mauritania, and of Pleïone, who were changed into the constellation which bears their name. They were Maia, Electra, Taygete, Sterope, Merope, Halcyone, and Celæno, who were also called *Atlantides*, from their father Atlas.

PLEIADES, an assemblage of seven stars, in the neck of the constellation Taurus. These stars are so called from the Greek πλέω, *to sail*, as being terrible to mariners, by reason of the rains and storms which frequently rise with them. The Latins called them *vergiliæ*, from *ver*, spring; because of their rising about the time of the vernal equinox.

PLEONASM (πλεονασμός, *excess*), a figure by which we may use words seemingly superfluous to express a thought with the greater energy; such as, "I saw it with my own eyes," "I heard it with my own ears," and the like.

PLESCHEN, or PLESZEW, a town of Prussia, in the province and government of Posen, and 54 miles S.E. of that town. It is not far from the Polish frontier; and has a considerable trade in horses and cattle which come from Poland. There are manufactured here shoes, cloth, tobacco, and potash. Pop. 4955.

PLETHORA (πληθώρη, *fulness*), in *Medicine*, is when the vessels are too much loaded with fluids. A plethoric state is marked by plumpness, fulness of countenance, a high colour, frequent dimness of sight, and ringing of the ears. It is often accompanied by corpulency, and a great accumulation of fat about the belly. It is generally the consequence of high living, of indolence, with much indulgence in sleep and luxury. Plethoric people are liable to a long train of dangers and inconveniences. They are apt to lose breath, to perspire on the slightest exertion, to headache, to vertigo, to palsy, to apoplexy, to bluntness of faculties, to stomach complaints, to low spirits, and a variety of other uncomfortable sensations. Bleeding is not considered good for plethora. In addition to regimen and the care of the general health, frequent purgatives are proper; and a course of mineral waters is frequently very salutary.

PLICA POLONICA, or PLAITED HAIR, is a disease in which the hairs are thicker than usual, and so entangled that it is impossible to separate them. It is peculiar to Poland, Lithuania, Hungary, and some neighbouring countries. Baron Larrey carefully investigated the nature of this disease when at Warsaw with the French army, and was perfectly satisfied that it is a local and factitious complaint, produced by dirt and neglect, and that it may be cured with safety. The head is to be shaved, and an ointment applied made of equal parts of sulphur ointment and pitch ointment, and the head is to be frequently washed with soap and water. Mercury, rubbed in with hair powder, is good for destroying the vermin. Internal remedies, such as Plummer's pill, or slight doses of calomel, may in some cases be necessary.

PLINIUS SECUNDUS, CAIUS, a Roman writer on natural history and other subjects, was born A.D. 23, in the tenth year of Tiberius, and died August 25, A.D. 79, in the first year of Titus. His birth-place has been the subject of considerable discussion; but the weight of testimony is thought to incline in favour of *Novum Comum*, now Como, in Cisalpine Gaul, in preference to Verona or (as suggested by Hardouin) Rome. His earlier years were passed probably at his native place; but while a youth he was enabled, by the affluence of his family, to remove to Rome, and attend the lectures of the grammarian Apion and other teachers of eminence. It was in his early life, probably, that he visited the provinces of Africa, Egypt, and Greece. In about his twenty-third year he served in Germany, under the *legatus* Pomponius Secundus, in command of a troop of cavalry. At this period he travelled over a great part of that country, visiting the sources of the Danube, the country of the Chauci (modern Oldenburg and Hanover), Belgic Gaul, and the shores of the German Ocean. It was in Germany, too, that he wrote his first work, a treatise, now lost, *On the Use of the Javelin by Cavalry*. In A.D. 52 he returned to Rome, and for a short time turned his attention to forensic pursuits,—a vocation in which he probably gained little or no distinction. On the death of Pomponius, who was equally celebrated as a general and as a poet, Pliny wrote his *Life*, in two books. During the earlier years of Nero's reign, he lived in retirement, and devoted the whole of his time probably to literary pursuits.

It was at this period, or somewhat earlier, that he completed a *History of the Wars in Germany*, in twenty books, which he had commenced while in that country (in obedience, the younger Pliny says, to the injunctions of a vision), and which, like his *Life of Pomponius Secundus*, is no longer extant. His next composition was a voluminous work, entitled *The Student*, in three books, and which, like most of his other works, has perished. It purported to be a manual for the training of an orator from infancy to his entrance upon public life. In the latter part of Nero's reign he wrote a treatise, in eight books, of which some fragments still survive, *On Ambiguities of Language*,—a work which, he informs us (*Hist. Nat.*, b. i.), made a great sensation among certain Stoics, logicians, and grammarians, but the doctrines of which they had not hitherto attempted to refute. Towards the close of the same reign, Pliny was appointed imperial *Procurator* in Nearer Spain, and, not improbably, at the same period was raised to equestrian rank. About A.D. 70 or 71 he returned to Rome, and, having been previously acquainted with the Emperor Vespasianus, was soon admitted into the number of his most intimate friends, and honoured with an appointment near his person, the nature of which is now unknown. During this reign, he completed his *Continuation of the Roman History of Aufidius Bassus*, in thirty-one books,—a work which he had previously commenced, but the publication of which, he says (*Hist. Nat.*, b. i.), he had determined to postpone until after his decease. No portion of it, unfortunately, has survived. It was in A.D. 77, probably, that he published his most important work, and the only one that has come down to us, his *Historia Naturalis*. From a remark in b. xix., c. 19, it would appear that he contemplated writing another work,—an intention probably which he did not live to realize.

In A.D. 73 or 74 Pliny had been appointed *Præfectus* of the Roman fleet stationed at Misenum, on the western coast of Italy; and to this he owed, remotely, his singular death, the details of which we learn from a letter of his nephew, the younger Pliny, to Tacitus the historian (b. vi., Ep. 16). Being at Misenum, and having his attention drawn to a cloud of unusual appearance arising from Mount Vesuvius, Pliny ordered a light vessel to be got ready, and, taking his tablets with him, embarked. Amid showers of ashes and pumice, he made his way into the midst of the danger, observing and noting down every change in the appearance of the phenomenon. It being found impossible to land at Retina, a village near Herculaneum, and the pilot advising him to return to Misenum, "Fortune favours the bold" was his answer; and he gave orders to steer for Stabiæ, in order to join Pomponianus there. On his arrival at Stabiæ, where for the moment the danger was not so imminent, he found his friend on the point of setting sail. Pliny prevailed upon him, however, to forego his intention, and requested the servants to conduct him to the bath. He then took his place at table, and dined, to all appearance without the least apprehension of danger. After again encouraging his friends and soothing their fears, he retired to rest, and soon fell asleep. Pomponianus, however, and the others, who in the meantime had sat up, finding the peril becoming more and more imminent, ordered him to be aroused; which done, they betook themselves to the open fields, tying pillows upon their heads to protect themselves from the falling stones. The sea being too tempestuous to allow of their embarking, Pliny now lay down upon a sail. Alarmed afresh, however, by the nearer approach of the flames, and making an effort to rise, he fell to the ground and expired, suffocated by the vapours no doubt, his chest being naturally contracted and his lungs weak. It was this eruption also which overwhelmed Herculaneum and Pompeii.

Of Pliny's habits, an interesting account has been preserved by his nephew in a letter addressed to Macer (b. iii., Ep. 5); from which we learn that but few moments of his life were left unemployed in literary pursuits. In summer he was in the habit of sitting up to a late hour at his studies; while in winter he would set to work at one or two in the morning, and sometimes at midnight even. After waiting upon the Emperor before daybreak, and executing his commissions, it was his practice to return home and resume his studies. Taking an early meal, he would, in summer, recline for a few moments in the sun, some book being read to him, and he making extracts in the meanwhile. Indeed this was his constant practice, for it was a favourite maxim with him, that "There was no book so bad but that some good might be got out of it." He would then take a cold bath, and, after a slight refreshment of food and rest, continue his literary pursuits till the evening meal. During this repast as well, some book was usually read to him, he making comments from time to time. Such was his mode of life when at Rome; and in the country there was no relaxation from his application to study. When on a journey his secretary was always by his side, ready to take down what he might dictate. By this economy of his time he amassed 160 volumes of notes, closely written on both sides; and for a portion only of which, when in Spain, one Largius Licinius offered him 400,000 sesterces. Pliny died unmarried.

For an insight into Pliny's sentiments upon religion and philosophy, virtue and vice, men and manners, we must have recourse to his *Natural History*, as our only source of information; and here even, not unfrequently, we are precluded from coming to any satisfactory conclusion, owing to the contradictions and obscurities that, equally from the compilatory nature of the work, the curtness of his style, the corruptness of the text, and the unsettled state of his opinions, so frequently present themselves. We have every reason to believe, however, that he was a man of high moral principles, and a lover, so far as his light extended, of virtue for its own sake. Impressed with great and noble sentiments, expressing his horror of bloodshed, debauchery, and drunkenness, and detesting that falsehood, meanness, and profligacy which so fearfully characterized imperial Rome, he loses no opportunity—to the extent of prejudice even—of proclaiming himself a *laudator temporis acti*, of extolling the simplicity of the olden times, and of leading us to suppose that he looked upon the elder Cato as his ideal of perfection, and considered his precepts to be little short of oracular. His religious and philosophical opinions were evidently of an unsettled character. In common with Lucretius and the Epicureans, he denies the existence of a Providence and the immortality of the soul; while, on the other hand, he adopts the Pythagorean notion of the harmony of the spheres, and agrees with the Stoics in considering the universe, or Nature, to be identical with the Deity, and in the belief that the world will ultimately be destroyed by fire. Pliny, it is evident, was not a rigid adherent of any sect of philosophy; but we may feel assured that he was a decided pantheist, and least unfavourable perhaps, as a whole, to the tenets of Epicurus. He appears, however, to have taken but a gloomy view of human existence and the dealings of God with man; so much so, that did we not learn from other sources that he had experienced no want of success in life, was in affluent circumstances, and enjoyed ample means for gratifying his literary tastes and caprices, we should have concluded that he was an eminently disappointed man, and that hence arose the dissatisfaction, which he omits no opportunity of expressing, with the terms upon which life has been granted to us. At the very earliest moment that the plan of his work will admit of his expressing the opinion (b. vii., c. 1), "It is far from easy to determine," says he, "whether Nature has proved to man a kind parent or a merciless stepmother,"—a complaint which is immediately followed up by repinings at the sad lot of man,—"The only tearful animal," he says.

Then, again (b. vii., c. 51), man's liability to disease is a blemish in the economy of Nature; and life is too short, and its tenure too uncertain. So sensitive is he upon the injustice of man being born to sorrow, that he expresses it as his conviction (b. vii., c. 41) that "no pleasure whatever can possibly compensate for the slightest grief." As life has not been granted on his own terms, he thinks it unworthy of his acceptance, and the sooner it is got rid of the better. Nature, in his opinion, has bestowed no greater blessing on man than a short life; sudden death he regards as a singular phænomenon, and as the supreme happiness of the human race; and the highest privilege that has been conferred upon us is the power that has been given to every one of putting an end to his own existence (b. xxviii., c. 2). "After burial," says he (b. vii., c. 56), "come the quiddities about the Manes (*Manium ambages*). All men, after their last day, return to what they were before the first; and after death there is no more sensation left in the body or in the soul than there was before birth." The doctrines of the immortality of the soul, of transmigration, and of a place for departed spirits, find equally little favour with him.

The faults presented by his work, valuable as it is, are of two kinds,—the one, the natural result of his own unsettled opinions on most matters of a speculative nature; the other, the consequence of his determination to embrace every subject included in the "*encyclopædia*" of the Greeks (b. i.), his want of discrimination, his ignorance of many of the subjects upon which he treats, his imperfect acquaintance probably with the language of his originals, and his unconscious prepossession for all that is strange, startling, and marvellous. Prone to censure credulity in others; equally averse, as he professes to be, to superstition and to scepticism; and a disbeliever, as he says, in omens, astrology, and magic,—there is nothing, it would appear, in some instances, that he is not ready, with a most astounding credulity, to believe; while, again, on other occasions, with an equally singular waywardness, he refuses to give credit where there is nothing in reality that ought in any way to stagger belief. Induced probably by the example of the elder Cato, his great prototype, he loses no opportunity of manifesting the strongest aversion to the Greeks, and brings repeated charges against them of viciousness, vanity, and lying; and yet to these same Greeks is he avowedly indebted for the larger and by far the more valuable part of his information upon most of the subjects of which he treats! A hater, too, of servility in others, he makes no scruple of falling in with the adulation of the day, whenever his subject leads him to mention his friend and patron the Emperor Vespasianus, and his sons Titus and Domitianus. Compiled, as his work is, from upwards of 2000 volumes, some errors might naturally be expected, and would be as readily forgiven; but so anxious is he for a large accumulation of facts, and those of as singular a nature as possible, that he inserts statements which a moment's consideration would have convinced the most credulous even must be destitute of all reasonable foundation. The result, too, of his own ignorance of many of his subjects is, that he is incapable of correcting the errors of those from whom he has borrowed, or of determining the relative value of the facts which he selects and of those which he omits. Much must have been left to his amanuenses, no doubt; and it is either to their carelessness and ignorance, or, what is equally probable, to his own imperfect knowledge of the language, that we must attribute his numerous incorrect translations from the Greek,—the works of Theophrastus in particular.

Pliny, in short, appears to have been actuated by a thirst for acquiring knowledge, from books, from oral information, and from personal observation, as ardent perhaps as that which influenced either Aristotle or our Lord Bacon, but without a particle of their genius, their powers of discernment, or their capacity for turning their acquisitions to practical account. The result is, that his *Historia Naturalis* cannot be viewed as a "Natural History" in our sense of the term, but as a vast compilation merely of asserted facts in meteorology, geography, zoology, botany, mineralogy, and therapeutics, and in the various arts more or less remotely connected with them. His work, however, is of inestimable value in many respects, and Cuvier, a man better qualified perhaps than any one else to give an opinion on the subject, while fully sensible of its imperfections, has awarded it a high rank among the most valuable productions of antiquity (*Biogr. Univers.*, vol. xxxv.) "This great work," he says, "is one of the most precious monuments left to us by antiquity, and a proof of the astonishing learning of a warrior and a statesman. To appreciate with justice this vast and celebrated composition, we must consider the plan, the facts, and the style. The plan is immense: it is his object to write, not merely a Natural History in our present restricted sense of the term—not a treatise, more or less detailed, on animals, plants, and minerals; but a work which embraces astronomy, physics, geography, agriculture, commerce, medicine, and the fine arts, in addition to natural history properly so called; while at the same time he continually interweaves with his narrative information relative to man considered metaphysically, and the history of nations,—so much so, indeed, that in many respects this work may be called the Encyclopædia of its age. It was impossible that, in treating, however cursorily, of such a prodigious number of subjects, the writer should not have recorded a multitude of remarkable facts; which to us are the more valuable as he is the only author extant who mentions them. Unhappily, the manner in which he has collected and arranged them causes them to lose much of their value; from his mixture of truth and fable, and more especially from the difficulty, and in some cases the impossibility, of discovering exactly of what objects he is speaking. Pliny was not an observer, like Aristotle; still less was he a man of genius, capable, like that philosopher, of seizing the laws and relations according to which Nature has regulated her productions. In general, he is only a compiler, and, indeed, mostly a compiler who, having no idea himself of the subjects on which he collects the testimonies of others, cannot appreciate the truth of those testimonies, nor even always understand what they mean. A comparison of his extracts with the original authors still extant, and especially with Aristotle, shows us that he was far from selecting either what was most important or most exact. In general, he prefers whatever is singular and marvellous, or what may help him in establishing the contrasts in which he so much delights, or the reproaches he is so fond of uttering against Providence. It is true that he does not give the same degree of faith to everything that he mentions, but it is quite by chance that he believes or doubts; and it is by no means the most childish stories that always provoke his incredulity. But if Pliny possesses little merit as a critic and a naturalist, it is far otherwise with his talent as a writer, and the immense treasury which he opens to us of Latin terms and forms of expression: these, from the very abundance of the subjects upon which he treats, render his work one of the richest repositories of the Roman language. Wherever he finds it possible to give expression to general ideas or to philosophical views, his language assumes considerable energy and vivacity, and his thoughts present a certain novelty and boldness which greatly tend to relieve the dryness of his enumerations, and, with the majority of his readers, excuse the deficiencies of his scientific information. He is always grave and noble, and everywhere shows a love of justice and virtue, a horror of that cruelty and baseness of which he had such frightful examples before his eyes, and a contempt for that unbridled luxury which in his time had so deeply corrupted the Roman people. For these great merits Pliny cannot be too highly praised; and, in spite of the faults which we cannot but recognise in him when viewed as a naturalist, we must nevertheless allow that he is one of the most meritorious of the Roman writers, and among the most worthy to be ranked in the number of the classics after the reign of Augustus."

The style of Pliny is often harsh, and always elliptical; so much so, that the brevity and conciseness which he seems more particularly to aim at not unfrequently degenerate into obscurity; relieved, however, by his general elevation of tone, his fondness for point and contrast, and touches of keen irony every now and then. With wit or genuine humour he seems to have had but little acquaintance, and we have but two or three faint traces of them throughout the work. Occasionally the context has the appearance of being little more than rough notes, hastily put together by himself, or left to the mercy of his scribes, and subjected to no revision before publication. This, combined with the corruptness of the text, renders it next to impossible, in some instances, to divine his meaning.

The following is a brief outline of the thirty-seven books into which the *Historia Naturalis* is divided:—The first contains the dedication to Titus, with a sketch of the plan proposed, and concludes with a summary of the contents of the other thirty-six, and a list of the authorities consulted in each. The second treats of the Deity, the universe, the earth, sun, moon, stars, and elements. In the next four books we have a geographical description (in most instances a bare recital of names) of the earth as known to the ancients; the sixth book, more particularly, being valuable for a detailed account of India, including *Taprobane*, the modern Ceylon. The seventh treats of man,—his organization, generation, and destiny; his virtues and vices, and his progress in the various arts and inventions. An account of beasts, fishes, birds, reptiles, and insects, with a sketch of human and comparative anatomy, forms the subject of the next four books. Botany is the main subject of the next sixteen books, which, though inartistically put together, are made to include a large amount of interesting information upon numerous subjects,—among them, perfumes, wines, oils, resins, fruits, trees, cabinet-woods, grafting, the culture of the vine and of the cereals, prognostics derived from various sources, flax, tissues, vegetables, garden-plants, chaplets, and chaplet-flowers; with an elaborate account, in books xxii.–xxvii., of the remedies derived from every portion of the vegetable world, and a description of the various diseases then known. In b. xxviii. he treats—and with much revolting detail—of the medicaments derived from the human body. In the next two books he describes the remedies derived from other living creatures, branching off into an account of the history of medicine and magic (which last he looks upon as an offshoot of the medical art), with some notices of the more current superstitions of the day. B. xxxi. and b. xxxii. are devoted to an account of medicinal waters, and the remedies derived from fish and other aquatic animals and productions. In b. xxxiii. and b. xxxiv. he gives a description of the various metals, with a large amount of miscellaneous information more or less remotely connected with them; his digressions embracing money, jewels, plate, bronzes, statues, and statuaries of all nations, with a correct table of their dates. B. xxxv. contains an account of mineral pigments and the art of painting, with copious notices of the more eminent painters, and of the various eras of the art. In b. xxxvi. he passes on to a description of stone and the other materials employed in building, the use of marble for the purposes of sculpture, the history of that art and of the more eminent sculptors and their works, the most remarkable buildings and works of art at Rome and elsewhere, concluding with a history of the invention and manufacture of glass. In b. xxxvii. he gives an account of gems, murrhine, amber, and precious stones; and concludes the work with a patriotic eulogium upon Italy, her productions, her fertility, her beauties, and her elevated rank among nations.

The earliest edition of the *Historia Naturalis* was published by J. De Spira, at Venice, 1469. The first edition of critical merit is that by Hardouin (Paris, 1685 and 1723). The most valuable critical edition is that by Sillig (Hamburg and Gotha, 1851–55, 6 vols. 8vo), the last six books being rendered additionally valuable by the new readings of a manuscript of the tenth or eleventh century, discovered at Bamberg, which has been admirably collated by M. Jan. In many passages previously looked upon as hopelessly corrupt, or else not at all suspected of being so, this manuscript supplies words and sentences which greatly tend to alter or elucidate the meaning; and by the aid of them Sillig has been enabled to *re-write* these books in a great degree. Twenty-two lines have also been added, from this manuscript, at the end of the work; before the discovery of which, both Jan and Sillig had expressed it as their opinion that the proper termination was wanting; and even now, notwithstanding the comparative completeness of the restored text, Bernhardy (*Grundriss d. Röm. Lit.*, p. 644, 2d ed.) is of opinion that there is still something wanting. From a perusal of these new readings, we may feel assured that the text of the earlier books is defective in the extreme; and much, no doubt, of the alleged obscurity of Pliny's style may be attributed to this cause. The best illustrated editions of the text are those published by Lemaire (Paris, 1827–33, 10 vols. 8vo), under various editors; and by Panckoucke (Paris, 1829–33, 20 vols. 8vo), with a French translation by Ajasson de Grandsagne, and notes by Cuvier, Fée, Parisot, and other learned men.

There are English translations of this work, by Philemon Holland (London, 1601, 2 vols. folio); and by Dr Bostock and H. T. Riley (London, 1855–57, 6 vols. 8vo), with copious illustrations of the text. (H. T. R.)

Plinius Cæcilius Secundus, *Caius*, commonly known as the "Younger Pliny," was the son of Caius Cæcilius, a person of equestrian rank, and of Plinia, the sister of the elder Pliny. His native place was probably *Novum Comum*, now Como; though Verona has been suggested. He was born A.D. 61 or 62; for we learn, from a letter of his to Cornelius Tacitus (b. vi., Ep. 20), that he was in his eighteenth year at the decease of his uncle, in A.D. 79. The time of his death is not known, but it is thought to have been towards the close of the reign of Trajanus, who died A.D. 117. Losing his father in early life, he was adopted by his uncle, then in Spain; upon whose return to Rome, A.D. 70 or 71, he was, with his mother, received under his roof. His education was conducted under the supervision of his uncle and his guardian Verginius Rufus, a person of consular rank, and of whom (b. ii., Ep. 1) he speaks in terms of grateful remembrance. In his fourteenth year he wrote a Greek tragedy, of which he does not speak in very flattering terms in after life (b. vii., Ep. 4). At Rome, he studied eloquence under Quintilianus and Nicetes Sacerdos. With his mother, he was residing with the elder Pliny at Misenum at the period of the great eruption of Vesuvius, and his death. At the age of nineteen he appeared as an advocate in the Forum, and was frequently employed in a similar capacity in the court of the *Centumviri*; as also in prosecutions before the Roman senate. While young he served as military tribune in Syria, where he met with Euphrates, the Stoic philosopher, and Artemidorus. After his return to Rome, he was appointed *Quæstor Cæsaris*, and was *Prætor* about A.D. 93. Towards the end of the reign of Domitianus, he drew upon himself the resentment of that emperor for his support of the cause of Helvidius, who was put to death. In A.D. 100 he was appointed Consul, upon which occasion he composed his Panegyric upon the Emperor Trajanus. In A.D. 103 he became *Pro-prætor* of the province of Pontica. He filled other offices also; and it is inferred from his letters (b. iii., Ep. 20; b. iv., Ep. 25) that he attained senatorial rank. His latter years were probably spent in retirement in Italy, his constitution being weak and his health delicate. He was twice married; his first wife dying about A.D. 96, the following year he married Calpurnia, who was considerably younger than himself,—a highly accomplished woman, and a member of an illustrious family. He had no children by either wife, born alive.

His character may be inferred from his letters. Somewhat credulous and superstitious, he was evidently an amiable man,—frugal, temperate, and in general humane; a promoter of learning, and on terms of intimacy with most of the literary men of his day. Possessing several villas on the banks of the Lake of Como, he was in the enjoyment of affluence; and he spent his money liberally, for the benefit of others as well as the improvement of his estates. He has been accused, however, of being jealous of the reputation of some of his friends; and that he was somewhat vain of his own acquirements, there is reason to believe.

The only extant works of Pliny are his *Panegyric upon Trajanus*, and his *Epistles*, in ten books. Very different estimates have been put upon the former. By some scholars it has been styled a work of surpassing excellence, and a model of eloquence; while by others it is stigmatized as a fulsome composition, and of little merit. Indeed, we are bound to admit that, in point of flattery, it oversteps modern notions of propriety, and that its style is too studied and formal: its chief value probably consists in what little information it gives us about the author and his times. The first nine books of the *Epistles* are addressed to various persons, and furnish the chief materials for Pliny's Life, with much interesting information about his contemporaries. The tenth book contains his letters to Trajanus during his government in Asia Minor, together with the Emperor's answers; an interesting series, which, it has been suggested, though on insufficient grounds, was not the genuine production of Pliny. Be this as it may, the collection forms a valuable accession to ancient literature, the merits of which are well described by Erasmus.—"The letters of Pliny," he says, "are redolent of wit, elegant, and appropriate: in them we read nothing but what pertains to everyday life, and everything is purely Latin, chaste, and ably described."

The two letters descriptive of the death and literary habits of the elder Pliny, and those addressed to Trajanus, with the answers, form the most interesting portions of the work. From the time of Tertullian, peculiar interest has been attached by the Christian world to Pliny's name, from the testimony which he bears (b. x., Ep. 97) relative to the character and tenets of the early Christians of his day,—the followers, as he calls them, of "a perverse and extravagant superstition." The conduct of Pliny, who was otherwise a humane man, towards the Christians of Bithynia, seems to have been cruel and intolerant; and his object is to ask the Emperor's advice as to his future proceedings, more particularly with the view of putting down their secret meetings. The Emperor's answer (b. x., Ep. 98), advising him to be lenient, and not too searching in his inquiries, is tempered with a spirit of mercy and justice, which unfortunately has not at all times characterized professing Christians themselves in their differences upon religion.

The first edition of the *Epistolæ* is that of Naples, 1476, folio; and of the *Panegyricus* and *Epistolæ*, that of Venice, 1485, 4to. The best edition of the entire works is that of Gierig (Leipsic, 1806, 2 vols. 8vo). The edition of the *Epistolæ* by Cortius and Longolius (Amst., 1734, 4to) is highly commended. There is also a very elaborate Life of Pliny by Masson (Amst., 1709, 8vo). There are two English translations of the *Epistolæ*,—one by Lord Orrery, the other by W. Melmoth; the latter probably the more meritorious of the two. (H. T. R.)

PLINTH. See Glossary to ARCHITECTURE.

PLOCK (Russian *Plozk*), a government of the Russian empire, in the kingdom of Poland, lying between N. Lat. 52. 15. and 53. 30., E. Long. 18. 45. and 22. 35.; and bounded on the E. by the government of Augustovo, S. by those of Lublin and Warsaw, W. and N. by Prussia; area, 6742 square miles. The Bug and the Vistula bound it on the S. and W., and the Narew, an affluent of the former river, flows through it from N. to S. A large part of the country is occupied with woods and marshes; but some parts of it consist of fine meadows and rich arable land. The government is divided into six circles. Pop. (1851) 548,406, including 30,803 Germans.

PLOCK, the chief town of the above government, on the right bank of the Vistula, 50 miles N.W. of Warsaw. It is well built on a hill in a fertile region; and contains an ancient cathedral with many interesting monuments, other Roman Catholic churches, and a Reformed church, several convents, an episcopal palace, schools of various kinds, an orphan hospital, lunatic asylum, and a theatre. A trade in corn, hides, &c., is actively carried on with Dantzic and other places. Pop. (1854) 12,728.

PLOËRMEL, a town of France, capital of an arrondissement, in the department of Morbihan, on the lake and river Duc, 25 miles N.E. of Vannes. The town is well built, and has wide, clean streets, two squares, and a public green. The parish church is a low, heavy building, containing interesting monuments of two of the dukes of Brittany. There are also here a college, hospital, and court-house. The inhabitants trade in hempen yarn, iron, cattle, woollen and linen stuffs, &c. The climate is very healthy. Pop. (1856) 4868.

PLÖN, a town of Denmark, in the duchy of Holstein, on a narrow neck of land separating the two lakes of Great and Little Plön, 17 miles S.E. of Kiel. The situation is very pleasant and picturesque. On a hill, rising steeply out of the lake, stands the castle, occasionally the residence of the Danish monarchs. It commands an extensive view over one of the most fertile regions of Holstein, consisting of hill and dale, wood and water, meadows and corn-fields. The town itself is very ancient, having been a celebrated place as early as the time when the Vandals held this country; but except the usual public buildings it has no structures of any importance. Pop. 3000. The great lake, irregular in form, 7 miles long and 4 broad, the largest in Holstein, is fringed with wood and studded with several islets.

PLOT, ROBERT, a learned antiquary and philosopher, was born at Sutton-Barne, in the parish of Borden, Kent, in the year 1641. He studied in Magdalen Hall, and afterwards in University College, Oxford. In 1682 he was elected secretary of the Royal Society, and published the *Philosophical Transactions* from No. 143 to No. 166 inclusive. The next year Elias Ashmole appointed him first keeper of his museum; and about the same time the vice-chancellor nominated him primarius professor of chemistry in the university of Oxford. In 1687 he was made secretary to the earl marshal; and the following year received the title of historiographer to James II. In 1690 he resigned his professorship of chemistry, and likewise his place of keeper of the museum, to which he presented a very large collection of natural curiosities, which he had described in his Histories of Oxfordshire and Staffordshire; the former published at Oxford in 1677, folio, and reprinted, with additions and corrections, in 1705, and the latter printed of the same size in 1686. In January 1694–5

Henry Howard, earl marshal, nominated him Mobray-herald extraordinary; two days after which he was constituted register of the Court of Honour; and, on the 30th of April 1696, he died of the stone, at his house at Borden.

As Dr Plot delighted in natural history, the above works were designed as essays towards a Natural History of England; and he had actually formed a design of travelling through England and Wales for that purpose. He accordingly drew up a plan of his scheme, in a letter addressed to Bishop Fell, which is inserted at the end of the second volume of Leland's *Itinerary*, in the edition of 1744. Amongst several manuscripts which he left behind him were large materials for the Natural History of Kent, Middlesex, and the city of London. Besides the above works, he published *De Origine Fontium Tentamen Philosophicum*, 8vo, and nine papers in the *Philosophical Transactions*.

PLOTINUS, the most celebrated writer and teacher of the Neo-Platonic school. He was born at Lycopolis, a city of Egypt, in A.D. 204, and began very early to show a great singularity both in his taste and in his manners. At the age of twenty-eight he had a strong desire to study philosophy, on which occasion he was recommended to the most famous professors of Alexandria. He was not satisfied with their lectures; but upon hearing those of Ammonius, he confessed that this was the man he wanted. He studied for eleven years under that excellent master, and then went to hear the Persian and Indian philosophers. In A.D. 243, when the Emperor Gordianus intended to wage war against the Persians, he followed the Roman army, but probably repented of it; for it was with difficulty he could save his life by flight after the emperor had been slain. He was then thirty-nine. The year following he went to Rome, and read philosophical lectures in that city; but avoided following the example of Erennius and Origen, his fellow-pupils, who having, like him, promised not to reveal some hidden and excellent doctrines which they had received from Ammonius, had nevertheless broken their pledge. Plotinus continued ten years in Rome without writing anything; but in his fiftieth year he obtained as his scholar Porphyry, who being of an exquisitely fine genius, was not satisfied with superficial answers, but required to have all difficulties thoroughly explained; and therefore Plotinus, to treat things with greater accuracy, was obliged to write more books. He had previously written twenty-one books, and during the six years of Porphyry's sojourn with him he wrote twenty-four, and nine after Porphyry left Rome, making in all fifty-four. The Romans had a high veneration for him; and he passed for a man of such judgment and virtue that many persons of both sexes, when they found themselves dying, entrusted him, as a kind of guardian angel, with the care of their estates and children. He was the arbiter of numberless lawsuits; and constantly behaved with such humanity and rectitude that he did not create a single enemy during the twenty-six years he resided in Rome. He did not meet with the same justice, however, from all of his own profession; for Olympias, a philosopher of Alexandria, being envious of his glory, used his utmost endeavours, though in vain, to ruin him. The Emperor Gallienus and the Empress Salonina had a very high regard for him; and if it had not been for the opposition of some jealous courtiers, they would have caused the city of Campania to be rebuilt, and given it to him, with the territory belonging to it, to establish a colony of philosophers, and to govern it according to the ideal laws of Plato's commonwealth. He laboured under various disorders during the last year of his life, which obliged him to leave Rome, when he was carried to Campania, to the heirs of one of his friends, who furnished him with everything necessary: and he died there, A.D. 270, at the age of sixty-six, in the noblest manner that a heathen philosopher could expire. "I am labouring with all my might," said he, "to return the divine part of me to the Divine Whole which fills the universe."

We have already remarked that the ideas of Plotinus were singular and extraordinary; and we shall now show that they were so. He was ashamed of being lodged in a body, for which reason he did not care to tell the place of his birth or family. The contempt he had for all earthly things was the reason why he would not permit his picture to be drawn; and when his disciple Amelius urged him to do so, "Is it not enough," said he, "to drag after us, whithersoever we go, that image in which nature has shut us up? Do you think that we should likewise transmit to future ages an image of that image, as a sight worthy of their attention?" On the same principle, he refused to attend to his health; for he never made use of preservatives or baths, and did not even eat the flesh of tame animals. He ate but little, and often abstained from bread; which, joined to his intense meditation, prevented him from sleeping. In short, he thought the body altogether below his notice, and had so little respect for it that he considered it as a prison, from which it would be his supreme happiness to be freed. When Amelius, after his death, inquired of the oracle of Apollo about the state of his soul, he was told that it was gone to the assembly of the blessed, where charity, joy, and a love of the union with God prevail. And the reason given for this, as related by Porphyry, is, "that Plotinus had been peaceable, gracious, and vigilant; that he had perpetually elevated his spotless soul to God; that he had loved God with his whole heart; that he had disengaged himself, to the utmost of his abilities, from this wretched life; that, elevating himself with all the powers of his soul, and by the several gradations taught by Plato, towards that Supreme Being which fills the universe, he had been enlightened by him, had enjoyed the vision of him without the help or interposition of ideas, and, in short, had often been united to him." This is the account of Porphyry, who also tells us that he himself had once been favoured with the vision. Plotinus had his familiar spirit as well as Socrates; but, according to Porphyry, it was not one of those called *demons*, but of the order of those who are called *gods;* so that he was under the protection of a spirit superior to that of other men. When Amelius desired him to share in the sacrifices which he used to offer up on solemn festivals, "It is their business," replied Plotinus, "to come to me; not mine to go to them."

Porphyry put the fifty-four books of Plotinus in order, and divided them into six *Enneades*. The greater part of them turn on the most high-flown ideas in metaphysics; and this philosopher seems, in certain points, to differ but little from Spinoza. He wrote two books to prove that all being is one and the same; which is, in fact, the very doctrine of Baruc Spinoza. He inquires, in another book, whether there are many souls, or only one. His manner of composing partook of the singularity of his nature. He never read over his compositions after he had written them; he wrote a bad hand, and was not exact in his orthography; he stood in need, therefore, of a faithful friend to revise and correct his writings; and he chose Porphyry for this purpose in preference to Amelius, who had been his disciple twenty-four years, and was very much esteemed by him. Marsilius Ficinus, at the request of Cosmo de' Medici, executed a Latin version of the works of Plotinus, with a summary and analysis of each book, which was printed at Basil, first by itself in 1559, and afterwards with the Greek in 1580, folio. His Life was written by Porphyry, the most illustrious of his disciples. A beautiful edition of the works of Plotinus, in 3 vols. 4to, has been published at the Oxford university press, with this title, *Plotini Opera Omnia Edidit Fredericus Creuser, Oxon. e typographeo*

Academico, 1835. There is also an English translation of *Select Works of Plotinus*, by Taylor.

PLOUGH. See Agriculture.

PLOWDEN, Edmund, sergeant at law, descended from an ancient family in Shropshire, was born in 1517, and was first a student of the university of Cambridge, where he spent three years in the study of philosophy and medicine. He then removed to Oxford, where having continüed his former studies about four years more, he was in 1552 admitted to the practice of physic and surgery; but probably finding the practice of the healing art less agreeable than the study of physic, he entered himself of the Middle Temple, and began to read law. Wood says that in 1557 he was summer reader to that society, and Lent reader three years afterwards, being then sergeant and oracle of the law. He died in the year 1584, aged sixty-seven; and was buried in the Temple church. He wrote *Commentaries or Reports of divers Cases in the reigns of Edward VI., Mary, and Elizabeth*, London, 1571, 1578, 1599, and 1613, written in the old Norman language; and *Queries, or a Moot-Book of Cases, translated, methodized, and enlarged*, by H. B. of Lincoln's Inn, London, 1662, in 8vo.

PLUCHE, Noel Antoine, a celebrated French writer, was born at Rheims in 1688; and having distinguished himself by his engaging manners and proficiency in the belles lettres, was appointed professor of humanity in the university of that city. Two years afterwards he obtained the chair of rhetoric, and was admitted into holy orders. The Bishop of Leon, informed of his talents, conferred upon him the direction of the college of his episcopal city. By his industry and superior knowledge, a proper order and subordination were soon established in it; but some peculiar opinions respecting the affairs of the time disturbed his tranquillity, and obliged him to resign his office. The intendant of Rouen, at the request of the celebrated Rollin, intrusted him with the education of his son. He published *Le Spectacle de la Nature*, in 9 vols. 12mo; *Histoire du Ciel*, or History of the Heavens, in 2 vols. 12mo (Voltaire called this work *Fable du Ciel*); *De Linguarum Artificio*, a work which he translated under the title of *Le Mécanique des Langues*, in 12mo; *Harmony of the Psalms and the Gospel*, or a translation of the Psalms and Hymns of the Church, with notes relative to the Vulgate, the Septuagint, and Hebrew Text, printed at Paris in 1764, in 12mo. In 1749 Abbé Pluche retired to Varenne St Maure, where he gave himself up entirely to devotion and study. He died of apoplexy, on the 20th of November 1761, at the age of seventy-three years.

PLUMB-LINE, or Plummet, an instrument used by carpenters, masons, and others, in order to judge whether walls or beams be upright planes, horizontal, or the like. It is so called from a piece of lead fastened to the end of a cord, which usually constitutes this instrument. Sometimes the string descends along a wooden ruler, raised perpendicularly on another, in which case it becomes a level.

PLUNKET, William Conyngham, *Baron*, Lord Chancellor of Ireland. This eminent lawyer, orator, and statesman, was the second son of the Rev. Thomas Plunket, a minister of the Church of Scotland in Ireland, and was born in the county of Fermanagh in July 1765. He was educated in boyhood by his father, who was a man of considerable abilities and reputation; and in 1779 he became a student of Trinity College, Dublin, having failed at his entrance in obtaining the humble honour of a sizarship. Though well versed in regular academic studies, as his writings and speeches abundantly prove, he was most conspicuous in his university career as the acknowledged leader of the Historical Society, the debating club of Trinity College, at this time full of young men of remarkable promise. In this arena, according to the tradition of his contemporaries, he showed from the first the powers of a great speaker; and he held an admitted superiority in an assembly among whose members were several orators of great future eminence.

Having entered Lincoln's Inn in 1784, Plunket was called to the Irish bar in 1787. His talents, acquirements, character, and station in life were calculated to insure him success in the profession of the law. If somewhat deficient in ready dexterity, his intellect was exactly that of a jurist or a great master of equity—not too refining or overprone to speculation, and yet capable of the highest legal generalizations, and of applying them to masses of fact, however tedious and complicated. His power of close and rapid argument was very remarkable, his memory equally capacious and exact, and he had enriched an ample store of professional learning with the fruits of assiduous general study. In addition, he was sedate and persevering in his disposition, his promise of eloquence was already acknowleged, and his fortune was sufficiently scanty to coerce him to submit to drudgery. Accordingly, although at first his progress at the bar was not rapid, he gradually obtained a considerable practice in equity; became known as a logical pleader and powerful advocate; and after an apprenticeship of eleven years as a junior, was raised to the rank of king's counsel in 1798.

In 1798 he entered the Irish Parliament as member for Charlemont. His political faith was already settled, and was only slightly modified in after life, at least as regards its cardinal tenets. He was an anti-Jacobin Whig of the school of Burke, not ungracefully filled with a fervent Irish patriotism. Having but little turn for speculation, he disliked the principles of the French Revolution, and its ferocious excesses made such an impression upon him that he always showed the greatest antipathy to merely democratic movements. But he was a sincere admirer of the constitutional government of England as established in 1688; he reverenced the predominance it secures to law and to the play of social forces; and he naturally loved its parliamentary and municipal institutions. He even justified the ascendancy it had given to the established church, although he thought that the time had at length arrived for extending toleration to Roman Catholics and Dissenters. To transfer it to Ireland as thus modified, and under an independent legislature, was, even in his youth, the only reform he sought for his country; and although he opposed the Union with all his power, this was only because he thought it incompatible with this object.

When Plunket became a member of Parliament, the Irish Whig party was almost extinct, and Mr Pitt was feeling his way to accomplish the Union. In this he was seconded ably by Lord Castlereagh, by the panic caused by a wild insurrection, and by the secession of Mr Grattan from politics. When, however, the measure was actually brought forward, it encountered a vehement opposition; and among the ablest and fiercest of its adversaries was Plunket, whose powers as a great orator were now universally recognised. His speeches in these debates show all the force of reasoning, the admirable arrangement, and the grasp of facts which characterize his later efforts; but they are somewhat disfigured by personal invective, and here and there betray an indecent acrimony. They raised him, however, immediately to the front rank of his party; and when Mr Grattan re-entered the moribund senate in which even his genius had been displayed in vain, he took his seat next to Plunket, thus significantly recognising the place he had attained.

After the union of Great Britain and Ireland Plunket returned to the practice of his profession, and became at once a leader of the equity bar. In 1803, after the outbreak of Emmet's rebellion, he was selected as one of the crown lawyers to prosecute the unfortunate enthusiast, and at the trial, in summing up the evidence, delivered a speech of remarkable power, which shows his characteristic dislike of revolutionary outbursts. For this speech he was exposed to much unmerited obloquy, and more especially to the libellous abuse of Cobbett, who could not endure his antipathy to democratic violence, and against whom he brought a successful action for damages. In 1804, in Mr Pitt's second administration, he became solicitor, and then attorney-general for Ireland; and he continued in office when Lord Grenville came into power at the head of the ministry of all the talents. Plunket held a seat in Parliament during this period; and when there, made several able speeches in favour of Catholic emancipation, and of continuing the war with France; but when the Grenville cabinet was dissolved, he returned once more to professional life, and for some years devoted himself exclusively to it.

In 1812, having amassed a considerable fortune, he re-entered Parliament as member for Trinity College, and identified himself thoroughly with the Grenville or anti-Gallican Whigs. He was now in the full maturity of his powers, and very soon was acknowledged one of the first, if not the first, orator of the House of Commons. His political tenets and his great abilities combined to secure him respect and admiration. His peculiar reverence for the English constitution in church and state, his strong dislike of French principles, his steady advocacy of the war with Napoleon, and his antipathy to anything like democracy, made him popular with the Tory party. On the other hand, he was the zealous and most able supporter of Catholic emancipation; he was not averse to some measure of parliamentary reform; and, as generally he was on the side of constitutional progress, he was reckoned a principal ornament of one of the sections of the Whigs. During the period between 1812 and 1822 his speeches on the Catholic question, on the renewal of the war in 1815, and on the "Peterloo massacre," as it was called, will alike indicate his position as a statesman, and give an idea of his oratorical abilities.

In 1822 Plunket was once more attorney-general for Ireland, with Lord Wellesley as lord-lieutenant. One of his first official acts was to prosecute for the "bottle riot;" an attempt on his part to put down the Orange faction in Ireland. But, though always the advocate of the Catholic claims, he strenuously opposed the Catholic Association, which about this time, under the guidance of Mr O'Connell, began its extraordinary and successful agitation. He struggled vehemently to extinguish it, and in 1825 made a powerful speech against it; and thus the curious spectacle was seen of the ablest champion of an oppressed sect doing all in his power to check its efforts to emancipate itself. And yet in this conduct it cannot be denied that Plunket was quite consistent with his principles of politics.

In 1827 Plunket was made master of the rolls in England; but, owing to the professional jealousy of the bar, who not unnaturally thought him an intruder, he was obliged to abandon this office. Soon afterwards he became chief justice of the common pleas in Ireland, and was then created an English peer. He was thus no longer a member of the House of Commons when the great measure of 1829 at length threw it open to the misgoverned sect of whom he had for many years been the chief advocate. In 1830 he was appointed lord chancellor of Ireland, and held the office, with an interval of a few months only, until 1841, when he finally retired from public life. During this period he made some able speeches in favour of parliamentary reform; but they were scarcely equal to his earlier efforts; and his reputation as a judge, though far from low, was not so eminent as might have been expected. He died in 1854, in his ninetieth year; and at his death the bar of Ireland held a general meeting to acknowledge their sense of his great qualities, and to devise a monument to his memory.

The eloquence of Lord Plunket is his best title to fame. It was remarkable for a felicitous exposition of principles not too recondite for the general hearer, and yet broad, deep, and comprehensive; for close, rapid, and vigorous reasoning; for perspicuous and well-arranged narrative; and for a diction, chaste, severe, and idiomatic—very rarely adorned with metaphor or antithesis, yet occasionally enriched with the most admirable illustrations, and frequently enlivened with a caustic and powerful satire. If it was wanting in anything, it was in passion; unlike that of Mr Fox, it never *subdued* the hearer; but it convinced him by a mingled display of argument, exposition, and irony, scarcely equalled even in the age of Brougham, Canning, and Lyndhurst. (W. O'C. M.)

PLURAL. See GRAMMAR.

PLUTARCH, one of the most celebrated writers of antiquity, was a native of Chæroneia in Bœotia. The exact date of his birth and death is unknown; but as he tells us that he studied philosophy under Ammonius at Delphi, when Nero made a tour through Greece, and as we know this circumstance to have taken place A.D. 66, we may place the birth of Plutarch towards the latter years of the reign of Claudius (A.D. 48–53). He was sprung from an honourable family, which had often been invested with the highest offices of the magistracy. He speaks of having seen his great-grandfather Nicarchus, from whom he learned, as from an eye-witness, the miseries which his country had suffered from the oppressions of Antony. His grandfather Lamprias was distinguished for his eloquence and imagination; and his father is praised for his modesty, his acquaintance with the theology of his time, and his knowledge of the works of the poets. Plutarch had two brothers, Timon and Lamprias; of the former of whom he says that he has no obligations to fortune so great as the enjoyment of his brother Timon's invariable friendship and kindness. Under Ammonius, of whom we know little more than what his pupil has told us, he acquired the doctrines of that humane and rational philosophy for which he was afterwards so distinguished. Upon what occasion he visited Italy is uncertain, but it is supposed to have been on some public business of the Chæroneians. Whilst he remained at Rome, he found his house resorted to by all the principal citizens, and his lectures on philosophy attended by the most illustrious of the Romans. Sossius Senecio, who was four times consul, once under Nerva and thrice under Trajan, was his most intimate friend. To him he addresses his *Lives*, except that of Aratus, which is inscribed to Polycrates of Sicyon, the grandson of Aratus. Whether he remained in Italy till all philosophers were banished from that country by a decree of Domitian, is a point of which we have no means of determining; but we know that he spent the greater part of his time in his native city. Here he devoted himself to the discharge of such humble duties as the magistrates of Chæroneia were required to perform; and we find that he also joined to his magisterial character the office of priest of Apollo. Suidas states that he was preceptor to Trajan; but he was so nearly contemporary with that emperor that little credit is due to this assertion. Plutarch was married to a lady of his native city, called Timoxena, and in his matrimonial connection he seems to have been particularly fortunate. By her he had five children, four sons and a daughter, who died young; and on this occasion he addressed a beautiful letter of consolation to his wife, which is highly honourable to both parties. Two only of his sons survived, Plutarch and Lamprias, the latter of whom appears to have been a philosopher; and it is to him that we are indebted for a catalogue of his father's writings. His nephew Sextus was of considerable eminence, and taught the Greek language to Marcus Antoninus. We have no particular account either as to the manner or the time of his death, only it is evident that he lived to a good old age. The most probable conjecture is that of Fabricius, who says he died in the fifth year of Hadrian, at the age of seventy.

His works have been divided, and they admit of a pretty equal division, into Lives and Morals,—the former of which, in his own estimation, were to be preferred, as more noble than the latter. His style has been excepted to with some reason. He has also been criticised for some mistakes in Roman antiquities, and for a partiality to the Greeks. On the other hand, he has been justly praised for the copiousness of his fine sense and learning, for his integrity, and for a certain air of goodness which appears in all he wrote. His business was not to please the ear, but to instruct and charm the mind; and in this none ever excelled him. The work which has immortalized Plutarch is his *Lives* of forty-six Greeks and Romans. The latest and best edition of the Greek text is that of C. Sintenis, Leipsic, 1839–46, 4 vols. 8vo. The translations are numerous. They have been done into French by Amyot, 1559, of which there is an English translation by Sir Thomas North, London, 1612, but unfortunately it does not always follow the French. Dryden's was by numerous hands, he having written only the dedication, and the Life of Plutarch attached. The English version of John and William Langhorne has frequently been printed. There is a good German translation by Kaltwasser, Magdeburg, 10 vols. 8vo, 1799–1806. The other writings of Plutarch, above sixty in number, are classed under the general name *Moralia*, or ethical works. The best edition of the Greek text is that of Wyttenbach, Oxford, 8 vols., 1795–1821. It has been done into French by Amyot, into German by Kaltwasser, and into English by various hands, 5 vols. 1684–94; but a good English translation of the *Morals* is still wanted.

PLUTO. See HADES.

PLUTUS, in Pagan worship, the god of riches, is frequently confounded with Pluto. He was represented as appearing lame when he approached, but provided with wings at his departure, to show the difficulty of amassing wealth and the uncertainty of its enjoyment. He was also represented blind, to show that he often bestowed his favours on the most unworthy, and left in necessity those who had the greatest merit.

PLYMOUTH, a town at the western extremity of the county of Devon, on the southern shore of England, 216 miles by road, and 247 by railway (*via* Bristol and Exeter) from the metropolis. It is situated at the head of the sound of the same name, and on the small river Plym, from which circumstance the prefix of its name is undoubtedly derived. It is a place which has grown to its present importance from the natural advantages of maritime access, and the capability of defence arising from local circumstances, which have been extended by liberal expenditure under the direction of men of the most scientific attainments.

The entrance to the harbour, or more properly harbours, of Plymouth, is not without its dangers, consisting of rocks and shoals. Of the former are the *Mewstone*, the *Shagstone*, and the *Renny;* and of the latter the *Tinker*, the *Shovel*, the *Knap*, and the *Panther;* but their position is so well known, and so accurately pointed out by buoys, that in all but the most tempestuous and foggy weather they are easily avoided. The first object deserving notice in the water-access to Plymouth is that part called the *Sound*, a most capacious anchoring place, capable of affording shelter and protection to 100 sail of the line. The Sound has been rendered secure by that prodigious display of human labour known by the name of the *Breakwater*. As a full and scientific description of that work has been given in a former volume (see vol. v., p. 306), we refer to it; only adding, that since the trial of the storms of 1816 and 1817, the strength as well as the utility of the work has been proved by a storm which took place on the 23d of November 1824, when the whole southern coast of England was bestrewed with wreck and desolation. The tide then rose to the frightful height of 26 feet 2 inches, whilst the mean rise of the water at spring-tides is usually only 18 feet. The greater part of the surface of the Breakwater was on that occasion completely overturned, and huge stones of from two to five tons each were carried from the outer and deposited on the inner slope. It need scarcely be remarked, that those liabilities to injury to which such a work as the breakwater is subject whilst in progress, will not exist in an equal degree when the work is completed. Thus, in a hurricane of January 1828 not a single stone of the finished part of the work was removed from its position. (See BREAKWATER.)

Within the breakwater there are many indentations, the mouths of which terminate in the *Sound*, and form excellent harbours, some of them adapted for the largest class of ships. The easternmost of these inlets is at first called Catwater, and extends to the Lake of Saltram, being crossed by the Lary Bridge, an elegant work, erected between the years 1824 and 1827, about 500 feet in length. The small river Plym rises in the Dartmoor Mountains, and empties itself into the Lake of Saltram. The next to Catwater is a capacious harbour, called Sutton Pool, which is capable of receiving a thousand sail. It is used chiefly by the largest class of merchant ships, and by the steam-packets; and it has several yards for repairing or building merchant vessels. The next harbour is called Mill Bay; it is chiefly used for commercial purposes, and has some good quays, some ship-building yards, and good moorings for steamboats. Beyond that, at the extreme west, which separates it from Cornwall, is that indentation which is of the most importance to the British navy. It is the harbour of Hamoaze, one of the finest in the world. It is open to the full force of the tide, but receives the stores of fresh water which fall into it from the rivers Tavy, Tamar, Lynher, and St Germains. It is the place where the men-of-war in ordinary are moored; and on its border are the extensive dock-yard, the gun-wharf, and the powder-magazine, which, with other objects, will hereafter be noticed. In Hamoaze, the admiral commanding the port has his flag displayed on his ship; and when surrounded, as he commonly is, by a hundred sail of vessels, a most impressive spectacle is presented to view afloat, whilst the picturesque objects on the shore tend to increase the effect.

Within the breakwater is Drake's or St Nicholas' Island. It is surrounded with rocks, has a strong castle and other fortifications, and is provided with furnaces for heating balls, and with other means of defence. It is of great importance, as commanding the entrance into Hamoaze, Catwater, and the other harbours.

Little is known of Plymouth prior to the time of the Norman conquest, when it was called *South Town* or *Sutton*, although under the Saxon dynasty it was called *Tamerweorth*. In the reign of Edward I. it was called *Sutton Prior* and *Sutton Valletort*, the northern parts being built on the lands of the prior of Plympton, and the southern parts on the estates of the Valletorts. At that period it was chiefly inhabited by fishermen. Under the fostering care of the priors the place made considerable advances, and the more appropriate name of *Plym-mouth* was given to it. The growing prosperity of the town excited the jealousy of France; and in 1339 a force from thence landed, and attempted to burn it. They succeeded in burning a portion, but were ultimately repulsed, with the loss of 500 men, by Hugh Courtenay, Earl of Devon, aided by a number of "knights and men of the countrie." A similar attempt was made in 1377, but with no great result; and after each, the fortifications were extended and strengthened. In 1335 the Black Prince embarked from Plymouth for France, and on his return to England he landed here with his prisoner, King John of France, who had been captured at the famous battle of Cressy. At the threatened invasion of England by the Spanish Armada, Plymouth was not behind the neighbouring maritime towns in providing for the defence of the kingdom, as we learn it contributed to the fleet "seven ships and one fly-boat." During the civil war between Charles I. and the Parliament, Plymouth was held by the troops of the latter party, who, though besieged, and almost reduced by famine, resisted for three years every effort of the royalists. After the restoration the citadel was erected; and in the reign of William III. the dockyard and the naval arsenal were established towards the west, upon the eastern shore of Hamoaze. Since that time it has gone on increasing; but the greatest progress has been made during the present century, in which it has assumed a new character, in the intelligence and wealth of the inhabitants, as well as in the architectural style of its buildings both public and private. The buildings collectively called Plymouth are comprehended in three divisions, now known, the first by that name, the second by that of Stonehouse, and the third by that of Devonport. The name of the last was, till August 1824, Plymouth Dock, when, on an application from the inhabitants, the present name was given by royal authority.

The population of the three ports, at the respective decennial enumerations, has been as follows:—

Ports.	1801.	1811.	1821.	1831.	1841.	1851.
Plymouth...	16,040	20,803	21,591	31,080	36,527	52,221
Stonehouse..	3,407	5,174	6,043	9,571	9,711	11,979
Devonport...	23,747	30,083	33,578	34,883	33,820	38,180
Total......	43,194	56,060	61,212	75,534	80,058	102,380

Plymouth was incorporated a borough by Henry VI. in the year 1439, and by that charter, and subsequent alterations of a trifling nature, was governed till 1835, when, by the law made to reform municipal corporations, it was divided into six wards, each choosing six councillors, who elect twelve aldermen, one of whom is appointed mayor. The borough returns two members to the House of Commons. The town is in the hundred of Roborough, and consists of two parishes, which are within the deanery of Plympton and the archdeaconry of Totness, in the diocese of Exeter. The church of the parish of St Andrews is interesting to the admirers of ancient architecture. It formerly belonged to a monastery; and many alterations having been made since its erection in 1440, various styles are exhibited in the building, which thus as a whole appears incongruous; and though handsome in parts, it wants, as regards the body of the church, that altitude which is the most essential ingredient of Gothic architecture. It consists of a nave of considerable dimensions, with aisles, and a chancel of great extent. The windows are mostly of the pointed style, and the tower, containing a fine peal of eight bells, must be admitted to be of good general proportions, and it is crowned by a pinnacled compartment of remarkable beauty.

The church of the other parish is known by the name of Charles church, probably in remembrance of the second king of that name, who divided the borough of Plymouth into two parishes, and erected this edifice. The tower and spire have an agreeable outline, but otherwise the exterior of the building can only be described as in the debased Gothic style of a degenerate period. Each of these churches has a chapel attached to it under the respective clergymen, which together contain sittings for 2700 persons. The populousness of the town has rendered the erection of several other churches imperative. The principal of the new buildings is dedicated to St James, and was erected in 1854-5, from a design by Mr St Aubyn. The several sects of Methodists, Baptists, Independents, Quakers, Roman Catholics, Unitarians, and Jews have their respective places of religious worship; but the first mentioned have by far the most numerous body of adherents. The Hoe or Howe at Plymouth is an eminence on the south side of the town. It is a healthy and pleasing promenade, stretching from Catwater to Mill Bay, on the eastern extremity of which is built the principal defence of this most important place, called the Citadel. The entrance to this work, on the side of the town, is through two gateways of a bad specimen of architecture. The buildings consist of houses for the governor and other officers, of barracks, an hospital, a magazine, an armoury, and a chapel. The fortification consists of three regular and two irregular bastions, the curtains of the regular bastions being strengthened by two ravelins and horn-works; on the east, north, and west sides are a deep ditch, counterscarp, and covered way, palisadoed, and the parapets are pierced for 120 cannon. The lower fort is connected with the citadel, and is chiefly intended to defend the Sound.

Amongst the public buildings of Plymouth, the most imposing is a noble pile, which comprehends the Royal Hotel, the assembly-rooms, and the theatre. The foundation was laid in September 1811, and the building was completed in 1818. The front is in the Ionic style, and nearly 100 yards in length. The expense of the erection, amounting to L.60,000, was defrayed partly by the corporation and partly by the institution of a tontine. The theatre is large, and is constructed with not less regard to the safety than to the accommodation of the audience.

The Athenæum is a fine building, erected by the Philosophical Institution, and completed in the year 1819. The portico exhibits four columns appropriate to the character of a building devoted to literature and art. The general style of the architecture is Doric, blended with the Grecian. In connection with the institution is a public library, which now contains a vast and well-selected collection of books.

The custom-house, erected at the commencement of the present century, is worthy of the town, and convenient for its commerce. It exhibits a front of granite, suitable, solid, and well proportioned. The interior is well arranged for business. On the ground floor are the offices of the principal surveyor, the tide-surveyor, the landing-waiter, the searchers, and others. A granite staircase leads to the long room, which is 54 feet in length, 26 in width, and 22 in height. This building was completed in 1820, at an expense of L.8000.

The Royal Baths is an elegant pile of building between Plymouth and Stonehouse. It is furnished with hot and cold baths of fresh or of sea water, of hot air, of sulphur, and of vapour. Within it has a pump-room, where a medicinal water is supplied from a spring, which is chiefly composed of muriates of soda, of magnesia, and of lime, combined with small proportions of sulphate and carbonate of lime, and a very minute portion of carbonate of iron. It is one of the best arranged institutions of its kind in England; and belongs to a joint-stock company, incorporated by charter in 1828.

An edifice was commenced in 1835 for an hospital and dispensary for South Devon and East Cornwall. At present the central part only is erected; but in the original plan it was contemplated to erect two wings, as soon as sufficient funds could be obtained for the purpose. These would double the capacity of the building as to beds, and supply other conveniences. There are in the centre part a theatre for operations and lectures, and wards for forty beds, with appropriate rooms for nurses and other attendants. Few towns have advanced so much within the last fifty years, in respect to its public buildings, as Plymouth. That advance is still progressive; and amongst the new erections may be noticed the town-hall, the gaol, the Botanical

Plymouth.

Society's hall, the mechanics' institute, and the free public library. In the first-named building is a fine portrait of the Prince Regent by Hoppner; and the latter has lately been augmented by the erection of a museum in the Ionic style, and which is well stored with curiosities. It bears the name of the Cottonian Museum, from the founder —— Cotton, Esq., F.R.S., of Plymouth. With all the improvements here noticed, it must be observed that the principal thoroughfares are irregular in their disposition, and that the most bustling street is the narrowest of the town; and though there are excellent shops of every description, some of them exhibiting fronts of chaste architectural character, yet they are incongruously to be seen among houses of very antique date and style. The northern part of the town consists of small but neat houses; but the best masses of buildings are at the west end, and they are chiefly occupied by persons in the legal, medical, or other professions.

The sanitary state of Plymouth has lately been much discussed. In 1853, in a report published by the General Board of Health, it was stated to be one of the most unhealthy towns in the kingdom; and the want of proper sewerage and drainage, combined with the impure and defective water supply, and the uncleanly state of many of the dwellings, especially those of the lower classes, have rendered the place pestilential; but lately some measures have been taken in order to stay these evils, and there is reason to hope that in the course of a few years the town will be restored to its former position as one of the most healthy in the southern part of the kingdom. The market for fish is very remarkable, both for the variety, the excellence, and the cheapness of that description of food. The market-days are Mondays, Thursdays, and Saturdays; and the market-place is spacious, comprising nearly 3 acres.

The maritime commerce of Plymouth is extensive. A great trade in timber is carried on with the Baltic, with America, and the Mediterranean; and there is a direct intercourse with the East and West Indies and Mauritius, which secures a good supply of tropical commodities. It is a bonding port for many articles, and especially for tobacco. There are also large importations of timber, hemp, tallow, and other articles, for the use of the dock-yard. The coasting trade is carried on principally with London, Newcastle, Newport in Monmouthshire, and Bristol. Great quantities of manganese are shipped to Scotland, lead to Bristol, and some wool to Hull. The docks have lately been extended at an immense cost. A great curiosity is the iron floating pier, 300 feet long and 40 feet wide. The amount of duty received at the custom-house during the past year (1857) considerably exceeded L.100,000. The number of sailing-vessels registered at Plymouth, December 31, 1857, was 425, tonnage 47,441; of steam-vessels 9, tonnage 332. In 1857 there entered 3333 sailing-vessels, tonnage 268,311; and 527 steam-vessels, tonnage 178,695: and there cleared 1771 sailing-vessels, tonnage 135,279; and 567 steam-vessels, tonnage 159,373. Besides these, there are more than fifty decked boats, called *trawlers*, employed in the extensive sea fishery, the produce of which is sent to Exeter, Bath, and even to London. The building and repairing of ships give occupation to some hundreds of persons.

Plymouth was in 1834 constituted a stannary town. The neighbouring tin and other mines are numerous and productive. The vicinity also abounds in quarries of granite, slate, and marble; the latter being highly esteemed for its veining and susceptibility of polish. The export of granite and the other stone is much facilitated by the tram-railway, 24 miles in length, which extends from the interior of Dartmoor to the quays of Catwater and Sutton Pool harbours. By the same means coal, lime, and manure are conveyed from the port to the interior. This railroad was executed by a joint-stock company formed in the year 1818, and was completed in 1820. The exchange for the merchants, erected in 1813, is near the custom-house; and amongst other institutions, it has a chamber of commerce, a marine insurance office, a steam-packet office, the oil-gas company's office, and an appropriate reading-room.

Plymouth.

Plymouth abounds with benevolent institutions, both of ancient and modern foundation. The workhouse, which is a corporate establishment, founded by several acts of Parliament, provides for a great number of paupers of both sexes and of all ages. Charles's alms-houses, founded by Charles II., Joy's alms-houses, the Household of Faith, the new alms-houses, the Mendicity Society, the Female Benevolent Society, and some others, are supported either by bequests, or by voluntary contributions, or by annual subscriptions. Most of the places of worship have schools attached to them; and there are a few endowed schools, and one grammar-school, from whose funds exhibitions are given to students at Oxford. Besides the hospital already noticed, there is a large public dispensary, and an infirmary for diseases of the eye. There is a medical society, with a professional library for the members of the healing art, embracing the entire field of medical literature. In 1815 a law library was established, the members of which consist exclusively of barristers and attorneys. The books are open for reference to any subscriber to the general library, to whose collection they have been recently united. The amusements of Plymouth are the stage, music, balls, annual races, and, what is more appropriate to the situation, regatta or marine races, in which the assistance of the Naval Yacht Club is afforded.

Stonehouse, the centre town of the group, received the name from Joel de Stonehouse, the lord of this domain in the reign of Henry III., before which it was called *Hippeston.* It has now descended to the Earl of Mount Edgecumbe, who, by granting leases on liberal terms, has assisted in that great increase of the town which the state of the population at the present time shows. These leases are granted on lives, renewable for ever at a fixed fine, and subject to an annual conventional rent. The town is joined with Plymouth by a thoroughfare street, and it occupies nearly the same level. The southern part is most on the increase, and is almost entirely occupied by genteel families, chiefly those of naval and military officers, and other persons holding situations under the government; but some other parts consist of small ill-built houses, which are occupied for the most part by the dock-yard artizans.

Stonehouse was constituted a township by the Reform Act, and exercises the elective franchise in connection with the borough of Devonport. It is divided into two wards, the east and the west, by the line of Brownlow Street. It is under the jurisdiction of a bench of magistrates. The poor are under the management of a governor, visitors, and guardians, in a workhouse, attached to which is a prison for vagrants and petty offenders, who are detained till they can be removed by the orders of the magistrates. The chief trade by water is in coals and timber; and the vessels discharge their cargoes on quays in the Pool, in which are accommodations for building ships.

The buildings devoted to public worship in connection with the Established Church are two ancient chapels dedicated to St George and St Paul, and two modern edifices, besides a chapel in connection with the Royal Naval Hospital, and which is open to the public. The Roman Catholics, Independents, both kinds of Methodists, the Baptists, Wesleyans, and others, have also places of worship; and most of them have schools for the instruction of those attending their respective public services.

An object that strikes every one in passing from Plymouth into Stonehouse is the establishment of the United Gas Company, at Mill Bay, by which the three towns in a direct line of nearly 4 miles are supplied with light.

The edifices belonging to the government are the most prominent objects in Stonehouse. One of these, the Marine Barracks, is on the western shore of Mill Bay, where there is a convenient landing-place. The buildings form an oblong square, in front of which are the apartments for the privates, whilst those of the officers are on the two sides. On the west side are the entrance-gate and a newly-erected guard-house. These barracks are handsomely and regularly built, have an hospital, and accommodate about 1000 men. The mess apartments are spacious and well furnished; and the officers have a very good library.

The Royal Naval Hospital is situated in the north-east part of Stonehouse. This important institution for the reception of sick and wounded marines and seamen was founded in 1762. It occupies a rising ground, and the area of the whole is about 24 acres, of which 13 are formed into a delightful place of exercise-ground for the convalescent patients. It consists of ten buildings, surrounding an extensive quadrangle, each containing six wards calculated to receive sixteen patients; but in cases of emergency the number can be extended to twenty. Thus as many as 1200 patients can be accommodated at one time. The superior officer is of the rank of post-captain in the navy, and has under him two lieutenants. The other officers are a physician, a surgeon, a steward, a dispenser, four hospital mates, several extra mates, and a chaplain.

The most remarkable object at Stonehouse is one only finished during the last reign, and hence bearing the name of the Royal William Victualling-Yard. It is situated close to the shore, upon which a most extensive marine terrace has been constructed, 50 feet broad, and nearly 1500 feet in length. It is entered from the land side by a magnificent gateway, under an arch surmounted by a statue of William IV., and two lateral ways. The whole of the building is of beautiful granite; and the shafts of the columns forming the internal avenue are each of one stone 36 feet high. After passing the gateway on the left are the neat granite-fronted residences of the two principal resident officers. On the right is the baking establishment, comprising a quadrangular range of buildings 250 by 200 feet, inclosing an architectural chimney-shaft of granite 150 feet in height. Further on is the Melville quadrangle, 240 feet square, with its rusticated granite archway (28 feet high), and the clock-chamber, of the same material, making together an elevation of 95 feet, and forming a magnificent centre-piece 61 feet in width. Opposite to this is the basin, 250 by 200 feet in extent, surrounded by quays of granite, save where an iron swing-bridge vaults over an opening of 45 feet into Stonehouse Pool. Answering the great bake-house, on the opposite of the basin, is the brew-house, similar in dimensions and in external character to the former, and having a corresponding chimney-shaft. Passing onwards in a direct line from the entrance, the irregular quadrangle of the cooperage is on the left, and beyond that the Clarence stores, which run along the quay of that name, 340 feet. There is also a reservoir for fresh water, elevated above most of the buildings, being 50 feet in height, neatly finished with granite and an iron railing, which contains 7000 tons. The Melville quadrangle includes the offices of the establishment, and, with the Clarence stores, are used as depôts for wet and dry provisions, and for slops for the seamen. In the brew-house a steam-engine is used in the operation of grinding malt, in mashing, and pumping. Two similar engines are employed in the bake-house, where there are twenty-five pair of millstones, affording the means of grinding a thousand bushels of meal in ten hours. In the same period flour is converted in the bake-house into ship biscuit, to the extent of 2450 lb. weight. The entire premises of this establishment occupy an extent of about 13 acres, of which one-half has been recovered from the sea, and the remainder excavated from the rock, the stone taken from which has been made use of to build a strong wall to defend the whole against the sea. The cost of this enormous establishment was above L.1,500,000.

Devonport, the third town of the group, is divided from Stonehouse by an arm of the sea, or inlet, over which there is now a bridge. It is in the parish of Stoke Damerel; and the ground on which it stands is for the most part the property of the St Aubyn family, whose steward holds a court-leet and a court-baron annually at Michaelmas, when a jury is sworn in, to prevent nuisances, and to appoint and swear in constables. Having been constituted a borough by the Reform Act, it now returns two members to Parliament; but the right of voting for them is also extended to the householders of Stonehouse. The town is locally governed by a mayor, twelve aldermen, and thirty-six councillors. It has also a bench of justices independent of the magistracy of Plymouth and Stonehouse.

The town of Devonport is supplied with water by a company established by act of Parliament 33 George III., which, by means of pipes, have brought from the Dartmoor Hills a stream of water which winds amongst the hills for thirty-seven miles, when it reaches a reservoir on the higher part of the town, whence it is distributed to the several streets and houses. The streets of the town are clean, and the whole has an appearance of great neatness; and two or three of these streets are of very handsome architecture. Several of the public buildings, though upon a small scale, are distinguished for the classical elegance of their architectural designs. The town-hall is distinguished by a Doric portico, in which the depth of the pronaos, and the elevation of the entrance-door upon a second internal landing, are features exciting great admiration. The columns are 27 feet 6 inches in height, and the lower diameters 5 feet 6 inches. The hall is 75 feet in length, 40 feet in width, and 31 feet in height. On the walls are portraits of Georges I., II., III., also of William IV., and of Queens Charlotte and Caroline. Within the building are cells for prisoners, offices for parochial purposes, and apartments occupied by the mechanics' institute. The library is an elegant erection, executed in 1823. The celebrated Denon, on seeing the design for this *façade*, pronounced it the best attempt to appropriate Egyptian architecture to domestic purposes that had ever come under his notice. The institution is designated the Civil and Military Library. It has a news-room, committee-room, and spacious library, already containing between 6000 and 7000 volumes, constantly augmenting; and besides, it possesses a comprehensive and valuable collection of minerals, presented by Sir John St Aubyn.

When the name of Devonport was given to this town, a column was erected to commemorate the grant, which now forms one of its chief architectural ornaments. This noble monument is of Devonshire granite, fluted, and of Doric proportions; measuring 65 feet 4 inches from the bottom of the shaft to the top of the capital, and making, with its inferior and crowning pedestals, a total altitude of 101 feet. Its height above the street, including the rock on which it stands, is 124 feet. A staircase of 140 steps leads to the gallery, the prospect from which will well repay the labour of ascending to it. Its cost of erection was L.2750.

The church of Stoke Damerel, the mother church of this very populous parish, being small, several chapels of ease have been erected. The principal of these is St Mary's, a neat structure of brick and stone, in the middle-pointed style of architecture, erected in 1851, from a design by St Aubyn: it presents a picturesque appearance; and consists of nave and chancel, with aisles, porch, and tower; above the tower rises a handsome spire to the height of 122 feet. The interior length of the edifice is about 110 feet. Mount Zion chapel, belonging to the Calvinists, exhibits an ingenious adaptation of Mohammedan architecture to Christian purposes. Though it has a strange, it has also a picturesque appearance; and the interior is capacious and commodious. St Aubyn's chapel is distinguished by its stone spire. It was built by subscription, under an act of Parliament, in 1771. St John's chapel was built in the same way, eight years later, at a cost of L.7700. The arrangement of the interior is curiously amphitheatrical. The roof embraces a clear span of 70 feet, the length of the chapel being 90 feet. Besides these episcopal chapels, a large one was built in the dock-yard by government in 1821. It was chiefly intended for the accommodation of the officers, civil, naval, and military, together with the operatives and soldiers belonging to the yard; but it is also open to the public. Besides the established churches, the Calvinist and Arminian Methodists, and the Independents and Baptists, have their places of worship, as well as the smaller sects of the Moravians and the Unitarians.

The government-house, on Mount Wise, near the grand parade, commands a southern view of much beauty. It contains every accommodation for carrying on the military government, and for the family of the governor. The front extends 200 feet. A large brass cannon, at the principal entrance, was taken from the Turks in the engagement of the Dardanelles. The port-admiral's house is near to it, on the north-west side, and comprises all the offices for the transaction of naval business, except that of courts-martial, which are always held on board the flag-ship in Hamoaze. At a short distance from it, on the top of the hill, is the *semaphore*, by which a constant communication is maintained between the office and the flag-ship, and which forms the first of a chain of telegraphs communicating with the Admiralty in London. The parade with its martial pomp and music, and Mount Wise with its charming walks and prospects, form a great source of pleasure to the inhabitants. To these may be added Richmond Walk, at the foot of Mount Wise, which leads to the public baths constructed at the joint expense of the navy and ordnance departments, and to the king's stairs, erected for access to the shore in 1820.

The most important object in Plymouth and its vicinity is the dock-yard. In the eighth volume of this work, under the article Dock-Yards, is a general description of this establishment, to which the reader is referred. To what is there stated we may add, that the whole dock-yard extends over 75 acres of land, of which about one-sixth is the property of the crown, and the remainder of Sir John St Aubyn, under a lease for twenty-one years, renewable every seven years with a fine of L.534, 4s. 6d., and an annual ground-rent of thirty shillings per acre.

The operations carried on within the yard give employment to upwards of 2000 men in time of peace, and the number of individuals depending on it for subsistence exceeds 7000. The chapel of the dock-yard is a fine building, the foundation of which was laid in 1814. The interior is elegantly fitted up. It is 100 feet in length and 75 in breadth, and has a tower with a set of bells. The erection is said to have cost L.24,000. In the year 1834 a police force was established as a civil guard to the dock-yard, consisting of a director, three inspectors, three sergeants, and forty constables.

The gun-wharf is an important part of this naval arsenal, on the north side of the dock-yard. It covers five acres of land. It contains storehouses filled with the various instruments of destruction; vast quantities of muskets, pistols, and cutlasses are deposited in chests or arranged in racks, or on the walls in the form of stars, circles, and crescents. Near these storehouses is the blacksmith's shop, and other buildings used as depositories for gun-carriages and the implements of the field-train. The intervals between the different edifices are occupied by piles of ordnance belonging to the ships in the harbour, with their respective names painted on the cannon. There are also large quantities of shot arrayed in pyramidical heaps, marked with the number contained in each pile. The vast portion of stores seen here, together with the armoury, form a sight worthy of attention.

Visitors, who are not foreigners, are permitted to inspect the whole of the dock-yard premises; they are, however, always accompanied by a constable. Foreigners must obtain an order for admission from the Admiralty.

Plymouth, a seaport of the United States of North America, state of Massachusetts, on Plymouth Bay, 35 miles S.E. of Boston. It is built chiefly of wood, and entirely in modern style, there being not a single antique building to remind the visitor that this is the oldest town of New England. The Pilgrim's Hall is a plain massive granite building, erected in 1824 by the Pilgrim Society, who meet annually here to commemorate the arrival here of the 101 pilgrim fathers, as they are called, in the Mayflower, December 22, 1620. In the hall there are several historical paintings and a cabinet of curiosities; and in front of the building is placed a part of the rock on which the emigrants first set foot. Some of the churches are handsome; and one occupies the site of that originally built by the pilgrims. Plymouth contains county buildings, banks, newspaper offices, cotton factories, &c. The inhabitants are largely engaged in the fisheries. The total tonnage of the port, June 30, 1852, was 3368 registered, and 9365 enrolled and licensed; the latter including 2538 tons employed in the coasting trade, 5169 in cod-fishing, and 1495 in mackerel-fishing. Pop. (1850) 6024.

PLYMPTON, two adjoining towns of England, county of Devon, on the left bank of the Plym, 4 miles N.E. of Plymouth, and 213 W.S.W. of London. Plympton St Mary, which lies to the N.W. of the other, contains no notable building, except the old lichen-tinted church, standing with its demons' heads and other grotesque ornaments in a lawn-like churchyard. Pop. of the parish (1851) 2815. Plympton Earle, or Plympton St Maurice, contains the ruins of a castle famous in the wars of King John and of the Commonwealth, crowning a knoll, near which stand the old granite church and the quaint grammar school with its high roof and piazza. The town contains many old houses, some of them raised on arches; and a venerable guildhall, bearing the date 1671. Plympton Earle was the birthplace of Sir Joshua Reynolds. Pop. (1851) 833.

PLYNTERIA (πλυντήρια, from πλύνειν, *to wash*), a Grecian festival in honour of Athena, who received from the daughter of Cecrops the name of Aglauros. During the solemnity they undressed the statue of the goddess and washed it. The day on which it was observed the people regarded as unfortunate and inauspicious; and therefore no person was permitted to appear in the temples, which were purposely surrounded with ropes. It was customary at this festival to bear in procession a cluster of figs, thus intimating the progress of civilization amongst the primitive inhabitants of the earth.

PNEUMATICS.

Air.

ACCORDING to the present usage of our language, this term is restricted to that part of natural philosophy which treats of mechanical properties of elastic fluids. The word, in its original meaning, expresses a quality of air, or more properly of breath.

Extent of the science.

We have extended the term PNEUMATICS to the study of the mechanical properties of all elastic or sensibly compressible fluids,—that is, of fluids whose elasticity and compressibility become an interesting object of our attention; as the term HYDROSTATICS is applied to the study of the mechanical properties of such bodies as interest us by their fluidity or liquidity only, or whose elasticity and compressibility are not familiar or interesting, though not less real or general than in the case of air and all vapours.

No precise limit to the different classes of bodies.

There is no precise limit to the different classes of natural bodies with respect to their mechanical properties. There is no such thing as a body perfectly hard, perfectly soft, perfectly elastic, or perfectly incompressible. All bodies have some degree of elasticity intermixed with some degree of ductility. Water, mercury, oil, are compressible; but their compressibility need not be attended to in order perfectly to understand the phenomena consequent on their materiality, fluidity, and gravity. But if we neglect the compressibility of air, we remain ignorant of the cause and nature of its most interesting phenomena, and are but imperfectly informed with respect to those in which its elasticity has no share; and it is convenient to attend to this distinction in our researches, in order to understand those phenomena which depend solely or chiefly on compressibility and elasticity. This observation is important; for here elasticity appears in its most simple form, unaccompanied with any other mechanical affection of matter (if we except gravity), and lies most open to our observation, whether employed for investigating the nature of this very property of bodies, or for explaining its mode of action. We shall even find that the constitution of an avowedly elastic fluid, whose compressibility is so very sensible, will give us the distinctest notions of fluidity in general, and enable us to understand its *characteristic appearances*, by which it is distinguished from solidity,—namely, the *equable* distribution of pressure through all its parts in every direction, and the horizontality which its surface assumes by the action of gravity; phenomena which have been assumed as equivalent to the definition of a perfect fluid, and from which all the laws of hydrostatics and hydraulics have been derived. And these laws have been applied to the explanation of the phenomena around us; and water, mercury, oil, &c., have been denominated fluid only because their appearances have been found to tally exactly with these consequences of this definition, while the definition itself remains in the form of an assumption, unsupported by any other proof of its obtaining in nature.

Air the most familiar compressible fluid.

Of all the sensible compressible fluids, air is the most familiar, was the first studied, and has been the most minutely examined. It has therefore been generally taken as the example of their mechanical properties, whilst those mechanical properties which are peculiar to any of them, and therefore characteristic, have usually been treated as an appendix to the general science of pneumatics.

Different properties of air.

But although the mechanical properties are the proper subjects of our consideration, it will be impossible to avoid considering occasionally properties which are more of a chemical nature; because they occasion such modifications of the mechanical properties as would frequently be unintelligible without considering them in conjunction with the other; and, on the other hand, the mechanical properties produce such modifications of the properties merely chemical, and of very interesting phenomena consequent on them, that these would often pass unexplained unless we give an account of them in this place.

Air.

Mechanical properties.

By mechanical properties we mean such as produce, or are connected with, sensible changes of motion, and which indicate the presence and agency of moving or mechanical powers. They are therefore the subject of mathematical discussion; admitting of measure, number, and direction. We shall therefore begin with the consideration of air.

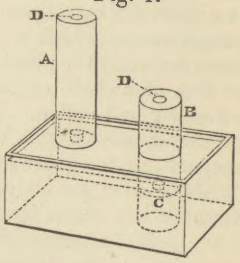
What is air?

It is by no means an idle question to put, What is this air of which so much is said and written? We see nothing, we feel nothing of it. We find ourselves at liberty to move about in any direction without any obstacle or hinderance. Whence, then, the assertion, that we are surrounded with a matter called air? A few very simple observations and experiments will show us that this assertion is well founded.

Proofs that it is matter

We are accustomed to say, that a vessel is empty when we have poured out of it the water which it contained. Take a cylindrical glass jar, having a small hole in its bottom; and having stopped this hole, fill the jar with water, and then pour out the water, leaving the glass empty, in the common acceptation of the word. Now, throw a bit of cork, or any light body, on the surface of water in a cistern; cover this with the glass jar A held in the hand with its bottom upwards, and move it downwards, as at B, keeping it all the while in an upright position. The cork will continue to float on the surface of the water in the inside of the glass, and will most distinctly show whereabouts that surface is. It will thus be seen, that the water within the glass has its surface considerably lower at C than that of the surrounding water; and however deep we immerge the glass, we shall find that the water will never rise in the inside of it so as to fill it. If plunged to the depth of 32 feet, the water will only half fill it; and yet the acknowledged laws of hydrostatics tell us, that the water would fill the glass if there were nothing to hinder it. There is therefore something already within the glass which prevents the water from getting into it; manifesting in this manner the most distinctive property of matter, viz. the hindering other matter from occupying the same place at the same time.

Fig. 1.



Possessed of impulsive force

While things are in this condition, pull the stopper D out of the hole in the bottom of the jar, and the water will instantly rise in the inside of the jar, and stand at an equal height within and without. This is justly ascribed to the escape through the hole of the matter which formerly obstructed the entry of the water; for if the hand be held before the hole, a puff will be distinctly felt, or a feather held there will be blown aside; indicating in this manner that what prevented the entry of the water, and now escapes, possesses another characteristic property of matter, *impulsive force*. The materiality is concluded from this appearance, in the same manner that the materiality of water is concluded from the impulse of a jet from a pipe. We also see the mobility of the formerly pent up, and now liberated substance, in consequence of external pressure, viz. the pressure of the surrounding water.

Impenetrability,

Also, if we take a smooth cylindrical tube, shut at one end, and fit a plug or cork to its open end, so as to slide along it, but so tightly as to prevent all passage by its sides; and if the plug be well soaked in grease, we shall find that no force whatever can push it to the bottom of the tube. There is therefore something within the tube preventing by its impenetrability the entry of the plug, and therefore possessing this characteristic of matter.

Elasticity,

In like manner, if, after having opened a pair of common bellows, we shut up the nozzle and valve hole, and try to bring the boards together, we find it impossible. There is something included which prevents this, in the same manner as if the bellows were filled with wool; but on opening the nozzle we can easily shut them, viz. by expelling this something; and if the compression be forcible, the something will issue with considerable force, and very sensibly impel any thing in its way.

Inertia, and mobility.

It is not accurate to say, that we move about without *any* obstruction: for we find, that if we endeavour to move a large fan with rapidity, a very sensible hinderance is perceived, and a sensible wind is produced, which will agitate the neighbouring bodies. It is therefore justly concluded that the motion is possible only in consequence of having driven this obstructing substance out of the way; and that this impenetrable, resisting, moveable, impelling substance, is matter. We perceive the perseverance of this matter in its state of rest when we wave a fan, in the same manner that we perceive the inertia of water when we move a paddle through it. The effects of wind in impelling our ships and mills, in tearing up trees, and overturning buildings, are equal indications of its perseverance in a state of motion. To this matter, when at rest, we give the name air; and when it is in motion we call it wind.

Air a material fluid.

Air, therefore, is a material fluid; a fluid, because its parts are easily moved, and yield to the smallest inequality of pressure. Air possesses some others of the very general, though not essential, properties of matter. It is heavy. This appears from the following facts.

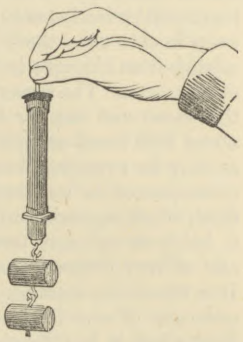
1. It always accompanies this globe in its orbit round the sun, surrounding it to a certain distance, under the name of atmosphere, which indicates the being connected with the earth by its general force of gravity. It is chiefly in consequence of this that it is continually moving round the earth from east to west; forming what is called the trade-wind, to be more particularly considered afterwards. All that is to be observed on this subject at present is, that, in consequence of the disturbing force of the sun and moon, there is an accumulation of the air of the atmosphere, in the same manner as of the waters of the ocean, in those parts of the globe which have the moon near their zenith or nadir: and as this happens successively, going from the east to the west, by the rotation of the earth round its axis in the opposite direction, the accumulated air must gradually flow along to form the elevation. This is chiefly to be observed in the torrid zone; and the generality and regularity of this motion are greatly disturbed by the changes which are continually taking place in different parts of the atmosphere from causes which are not mechanical.

2. It is in like manner owing to the gravity of the air that it supports the clouds and vapours which we see constantly floating in it. We have even seen bodies of no inconsiderable weight float, and even rise, in the air. Soap bubbles, and balloons filled with inflammable gas, (hydrogen or gas obtained from oil or coal,) rise and float in the same manner as a cork rises in water. This phenomenon proves the weight of the air, in the same manner that the swimming of a piece of wood indicates the weight of the water which supports it.

Familiar proofs of its weight.

3. But we are not left to these refined observations for the proof of the air's gravity. We observe many familiar phenomena, which must be immediate consequences of the supposition that air is a heavy fluid, and, like other heavy fluids, presses on the outsides of all bodies immersed in or surrounded by it. Thus, for instance, if we shut the nozzle and valve hole of a pair of bellows after having squeezed the air out of them, we shall find that even some hundred pounds, are necessary for separating the boards. They are kept together by the pressure of the heavy air which surrounds them in the same manner as if they were immersed in water. In like manner, if we stop the end of a syringe after its piston has been pressed down to the bottom, and then attempt to draw up the piston, we shall find a considerable force necessary, viz. about fifteen or sixteen pounds for every square inch of the section of the syringe. Exerting this force, we can draw up the piston to the top, and we can hold it there; but the moment we cease acting, the piston rushes down and strikes the bottom. It is called a suction, as we feel something as it were drawing in the piston; but it is really the weight of the incumbent air pressing it in. And this obtains in every position of the syringe; because the air is a fluid, and presses in every direction. Nay, it presses on the syringe as well as on the piston; and if the piston be hung by its ring on a nail, the syringe requires force to draw it down, just as much as to draw the piston up; and if it be let go, it will spring up unless loaded with at least fifteen pounds for every square inch of its transverse section. See fig. 2.

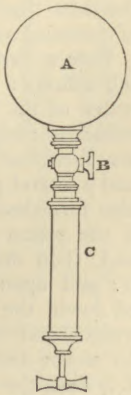
Fig. 2.



It may even be weighed.

4. But the most direct proof of the weight of the air is had by weighing a vessel empty of air, and then weighing it again when the air has been admitted; and this, as it is the most obvious consequence of its weight, has been asserted as long ago as the days of Aristotle. If we take a very large and limber bladder, and squeeze out the air very carefully, and weigh it, and then fill it till the wrinkles just begin to disappear, and weigh it again, we shall find no difference in the weight. But this is not Aristotle's meaning: because the bladder, considered as a vessel, is equally full in both cases, its dimensions being changed. We cannot take the air out of a bladder without its immediately collapsing. But what would be true of a bladder would be equally true of any vessel. Therefore, take a round vessel A, (fig. 3,) fitted with a stopcock B, and syringe C. Fill the whole with water, and press the piston to the bottom of the syringe. Then keeping the cock open, and holding the vessel upright, with the syringe undermost, draw down the piston. The water will follow it by its weight, and leave part of the vessel empty. Now shut the cock, and again push up the piston to the bottom of the syringe, the water escapes through the piston valve, as will be explained afterwards; then opening the cock, and again drawing down the piston, more water will come out of the vessel. Repeat this operation till all the water have come out. Shut the cock, unscrew the syringe, and weigh the vessel very accurately. Now open the cock, and admit the air, and weigh the vessel again, it will be found heavier than before, and this additional weight is the weight of the air which fills it; and it will be found to be 523 grains, about an ounce and a fifth avoirdupois, for every cubic foot that the vessel contains. Now since a cubic foot of water would weigh 1000 ounces, this experiment would show that water is about 840 times heavier than

Fig. 3.



air. The most accurate judgment of this kind of which we have met with an account, is that recorded by Sir George Shuckburgh, in the sixty-seventh volume of the Philosophical Transactions, (p. 560.) From this it follows, that when the air is of the temperature 53, and the barometer stands at 29¼ inches, the air is 836 times lighter than water. But the experiment is not susceptible of sufficient accuracy for determining the exact weight of a cubic foot of air. Its weight is very small; and the vessel must be strong and heavy, so as to overload any balance that is sufficiently nice for the experiment.[1]

The most convenient method of doing this.

To avoid this inconvenience, the whole may be weighed in water, first loading the vessel so as to make it preponderate an ounce or two in the water. By this means the balance will be loaded only with this small preponderancy. But even in this case there are considerable sources of error, arising from changes in the specific gravity of the water and other causes. The experiment has often been repeated with this view, and the air has been found at a medium to be about 840 times as light as water, but with great variations, as may be expected from its very heterogeneous nature, in consequence of its being the menstruum of almost every fluid, of all vapours, and even of most solid bodies; all which it holds in solution, forming a fluid perfectly transparent, and of very different density according to its composition. It is found, for instance, that perfectly pure air of the temperature of our ordinary summer is considerably denser than when it has dissolved about half as much water as it can hold in that temperature; and that with this quantity of water the difference of density increases in proportion as the mass grows warmer, for damp air is more expansible by heat than dry air. We have had occasion to consider this subject when treating of the connection of the mechanical properties of air with the state of the weather.

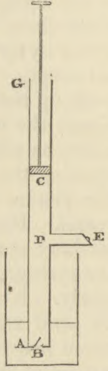
This property of air denied by the Peripatetics.

Such is the result of the experiment suggested by Aristotle, evidently proving the weight of the air; and yet the Peripatetics uniformly refused it this property. It was a matter long debated among the philosophers of the last century. The reason was, that Aristotle assigns a different cause to many phenomena which any man led by common observation would ascribe to the weight of the air. Of this kind is the rise of water in pumps and syphons. Aristotle had asserted that all nature was full of being, and that nature abhorred a void. He adduces many facts, in which it appears, that if not absolutely impossible, it is very difficult, and requires great force, to produce a space void of matter. When the operation of pumps and syphons came to be known, the philosophers of Europe, found in this fancied horror a ready solution of the phenomena. We shall state the facts that every reader may see what kind of reasoning was received not two centuries ago.

Construction of pumps in the last century.

Pumps were then constructed in the following manner: A long pipe GB was set in the water of the well A. This was fitted with a sucker or piston C, having a long rod CF, and was furnished with a valve B at the bottom, and a lateral pipe DE at the place of delivery, also furnished with a valve. The fact is, that if the piston be thrust down to the bottom, and then drawn up, the water will follow it; and upon the piston being again pushed down, the water shuts the valve B by its weight, and escapes or is expelled at the valve E; and on drawing up the piston again the valve E is shut, the water again rises after the piston, and is again expelled at its next descent.

Fig. 4.



The Peripatetics explain all this by saying, that if the water did not follow the piston there would be a void between them. But nature abhors a void; therefore the water follows the piston; this reasoning is overturned by one observation. Suppose the pipe shut at the bottom, the piston can be drawn up, and thus a void produced.

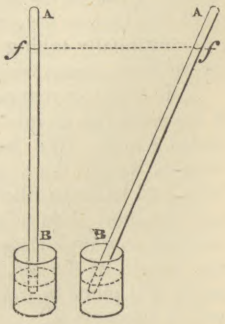
Galileo first predicted the height to which water would rise.

Galileo seems to have been the first who seriously ascribed this to the weight of the air. Many had supposed air heavy; and thus explained the difficulty of raising the board of bellows, or the piston of a syringe, &c. But he distinctly applies to this allowed weight of the air all the consequences of hydrostatical laws; and he reasons as follows. The heavy air rests on the water in the cistern, and presses it with its weight. It does the same with the water in the pipe, and therefore both are on a level: but if the piston, after being in contact with the surface of the water, be drawn up, there is no longer any pressure on the surface of the water within the pipe; for the air now rests on the piston only, and thus occasions a difficulty in drawing it up. The water in the pipe, therefore, is in the same situation as if more water were poured into the cistern, that is, as much as would exert the same pressure on its surface as the air does. In this case we are certain that the water will be pressed into the pipe, and will raise up the water in it, and follow it till it is equally high within and without. The same pressure of the air shuts the valve E during the descent of the piston. He did not wait for the very obvious objection, that if the rise of the water was the effect of the air's pressure, it would also be its measure, and would be raised and supported only to a certain height. He directly said so, and adduced this as a decisive experiment. If the horror of a void be the cause, says he, the water must rise to any extent however great; but if it be owing to the pressure of the air, it will only rise till the weight of the water in the pipe is in equilibrio with the pressure of the air, according to the common laws of hydrostatics. And he adds, that this is well known; for it is a fact, that pumps will not *draw* water much above forty palms, although they may be made to *propel* it, or to *lift it* to any height. He then makes an assertion, which, he says, if true, will be decisive. Let a very long pipe, shut at one end, be filled with water, and let it be erected perpendicularly with the close end uppermost, and a stopper in the other end, and then its lower orifice immersed into a vessel of water; the water will subside in the pipe upon removing the stopper, till the remaining column is in equilibrio with the pressure of the external air. This experiment he proposes to the curious; saying, however, that he thought it unnecessary, there being already such abundant proofs of the air's pressure.

His prediction verified.

It is probable that the cumbersomeness of the necessary apparatus protracted the making of this experiment. Another equally conclusive, and much easier, was made in 1642 after Galileo's death, by his zealous and learned disciple Toricelli. He filled a glass tube, close at one end, with mercury; judging, that if the support of the water was owing to the pressure of the air, and was the measure of this pressure, mercury would in like manner be supported by it, and this at a height which was also the measure of the air's pressure, and therefore thirteen times less than water. He had the pleasure of seeing his expectation verified in the completest manner; the mercury descending in the tube AB, and finally settling at the height

Fig. 5.



---

[1] This method as here stated requires a strong vessel, and consequently overloads a delicate balance; but the objection does not apply when water is not used, and the flask weighed, first when full of air, and again when the air has been exhausted by the air-pump to a known amount; in this way the specific gravity of any gas may be determined.

*f*B of $29\frac{3}{4}$ Roman inches: and he found, that when the tube was inclined, the point *f* was in the same horizontal plane with *f* in the upright tube, according to the received laws of hydrostatical pressure. The experiment was often repeated, and soon became famous. About three years afterwards the same experiment was published, at Warsaw in Poland, by Valerianus Magnus, as his own discovery: but it appears from the letters of Roberval, not only that Toricelli was prior, and that his experiment was the general topic of discussion among the curious; but also highly probable that Valerianus Magnus was informed of it when at Rome, and daily conversant with those who had seen it. He denies, however, even having heard of the name of Toricelli.

Origin of the Royal Society.

This was the era of philosophical ardour; and we think that it was Galileo's invention and immediate application of the telescope which gave it vigour. Discoveries of the most wonderful kind in the heavens, and which required no extent of previous knowledge to understand them, were thus put into the hands of every person who could purchase a spy-glass; whilst the high degree of credibility which some of the discoveries, such as the phases of Venus and the rotation and satellites of Jupiter, gave to the Copernican system, immediately set the whole body of the learned in motion. About the years 1642 and 1644 we find clubs of gentlemen associated in Oxford and London for the cultivation of knowledge by experiment; and before 1655 all the doctrines of hydrostatics and pneumatics were familiar there, and established by experiment. Mr. Boyle procured a coalition of these clubs under the name of the Invisible and Philosophical Society. In May 1658 Mr. Hooke finished for Mr. Boyle an air-pump, which had employed him a long time, and occasioned him several journeys to London for things which the workmen of Oxford could not execute. He speaks of this as a great improvement on Mr. Boyle's own pump, which he had been using some time before. Boyle therefore must have invented his air-pump, and was not indebted for it to Schottus's account of Otto Guerické's, published in the *Mechanica Hydraulo-pneumatica* of Schottus in 1657, as he asserts *Technica Curiosa.* The Royal Society of London arose in 1656 from the coalition of these clubs, after fifteen years' co-operation and correspondence. The Montmorine Society at Paris had subsisted nearly about the same time; for we find Pascal in 1648 speaking of the meetings in the Sorbonne College, from which we know that society originated. Nuremberg, in Germany, was also a distinguished seminary of experimental philosophy. The magistrates, sensible of its valuable influence in many manufactures, the source of the opulence and prosperity of their city, and many of them philosophers, gave philosophy a professed and munificent patronage, furnishing the philosophers with a copious apparatus, a place of assembly, and a fund for the expence of their experiments; so that this was the first academy of sciences out of Italy under the patronage of government. In Italy, indeed, there had long existed institutions of this kind. Rome was the centre of church-government, and the resort of all expectants for preferment. The clergy was the majority of the learned in all Christian nations, and particularly of the systematic philosophers. Each, eager to recommend himself to notice, brought forward every thing that was curious; and they were the willing vehicles of philosophical communication. Thus the experiments of Galileo and Toricelli were rapidly diffused by persons of rank, the dignitaries of the church, or by the monks their obsequious servants.

Toricellian experiment, repeated in various forms.

All now agree in giving Toricelli the honour of the first invention; and it universally passes by the name of the Toricellian Experiment. The tube is called the Toricellian tube; and the space left by the mercury is called the Toricellian Vacuum, to distinguish it from the Boylean Vacuum, which is only an extreme rarefaction. The experiment was repeated in various forms, and with apparatus which enabled philosophers to examine several effects which the vacuum produced on bodies exposed to it. This was done by making the upper part of the tube terminate in a vessel of some capacity, or communicate with such a vessel, in which were included along with the mercury bodies on which the experiments were to be made. When the mercury had run out, the phenomena of these bodies were carefully observed.

An objection to the conclusion drawn from it obviated.

An objection was made to the conclusion drawn from Toricelli's experiment, which appears formidable. If the Toricellian tube be suspended on the arm of a balance, it is found that the counterpoise must be equal to the weight both of the tube and of the mercury it contains. This could not be, say the objectors, if the mercury were supported by the air. It is evidently supported by the balance; and this gave rise to another notion of the cause different from the Peripatetic *fuga vacui.* A suspensive force, or rather attraction, was assigned to the upper part of the tube.

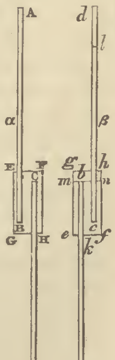
But the true explanation of the phenomena is most easy and satisfactory. Suppose the mercury in the cistern and tube to freeze, but without adhering to the tube, so that the tube could be freely drawn up and down. In this case the mercury is supported by the base, without any dependence on the pressure of the air; and the tube is in the same condition as before, and the solid mercury performs the office of a piston to this kind of syringe. Suppose the tube thrust down till the top of it touches the top of the mercury. It is evident that it must be drawn up in opposition to the pressure of the external air, and it is precisely similar to the syringe in fig. 2. The weight sustained therefore by this arm of the balance is the weight of the tube and the downward pressure of the atmosphere on its top.

Galileo's original experiment performed.

The curiosity of philosophers being thus excited by this very manageable experiment, it was natural now to try the original experiment proposed by Galileo. Accordingly Berti in Italy, Pascal in France, and many others in different places, made the experiment with a tube filled with water, wine, oil, &c., and all with the success which might be expected in so simple a matter: and hence the doctrine of the weight and pressure of the air was established beyond contradiction or doubt. All this was done before the year 1648. A very beautiful experiment was exhibited by Auzout, which completely satisfied all who had any remaining doubts.

A decisive experiment by Auzout.

Fig. 6.



A small box or vial EFGH, had two glass tubes, AB, CD, three feet long, inserted into it in such a manner as to be firmly fixed in one end, and to reach nearly to the other end. AB was open at both ends, and CD was close at D. This apparatus was completely filled with mercury, by unscrewing the tube AB, filling the box and the tube CD; then screwing in the tube AB, and filling it; then holding a finger on the orifice A, the whole was inverted and set upright in the position represented in the figure β, immersing the orifice A (now *a* of fig. β,) in a small vessel of quicksilver. The result was, that the mercury ran out at the orifice *a*, till its surface *m n* within the phial descended to the top of the tube *b a*. The mercury also began to descend in the tube *d c* (formerly DC,) and run over into the tube *b a*, and run out at *a*, till the mercury in *d c* was very near equal in a level with *m n*. The mercury descending in *b a* till it stood at *k*, $29\frac{1}{2}$ inches above the surface *o p* of the mercury in the cistern, just as in the Toricellian tube.

The rationale of this experiment is very easy. The whole apparatus may first be considered as a Toricellian tube of an uncommon shape, and the mercury would flow out at *a*. But as soon as a drop of mercury comes out, leaving a space above *m n*, there is nothing to keep up the mercury in the tube $d\,c$. Its mercury, therefore, descends also; and running over into $b\,a$, continues to supply its expence till the tube $d\,c$ is almost empty, or can no longer supply the waste of $b\,a$. The inner surface therefore falls as low as it can, till it is level with b. No more mercury can enter $b\,a$, yet its column is too heavy to be supported by the pressure of the air on the cistern below; it therefore descends in $b\,a$, and finally settles at the height $k\,o$, equal to that of the mercury in the Toricellian tube.

The prettiest circumstance of the experiment remains. Make a small hole g in the upper cap of the box. The external air immediately rushes in by its weight, and now presses on the mercury in the box. This immediately raises the mercury in the tube $d\,c$ to l, $29\frac{1}{2}$ inches above $m\,n$. It presses on the mercury at k in the tube $b\,a$, balancing the pressure of the air in the cistern. The mercury in this tube therefore is left to the influence of its own weight, and it descends to the bottom. Nothing can be more apposite or decisive.

The gravity of the air a statical principle.

And thus the doctrine of the gravity and pressure of the air is established by the most unexceptionable evidence; and we are entitled to assume it as a statical principle, and to affirm *a priori* all its legitimate consequences.

And in the first place, we obtain an exact measure of the pressure of the atmosphere. It is precisely equal to the weight of the column of mercury, of water, of oil, &c. which it can support; and the Toricellian tube, or others fitted up upon the same principle, are justly termed *baroscopes* and *barometers* with respect to the air. Now it is observed that water is supported at the height of 32 feet nearly: the weight of the column is exactly 2000 avoirdupois pounds on every square foot of base, or $13\frac{9}{10}$ on every square inch. The same conclusion very nearly may be drawn from the column of mercury, which is nearly $29\frac{1}{2}$ inches high when in equilibrium with the pressure of the air. We may here observe, that the measure taken from the height of a column of water, wine, spirits, and the other fluids of considerable volatility, as chemists term it, is not so exact as that taken from mercury, oil, and the like. For it is observed, that the volatile fluids are converted by the ordinary heat of our climates into vapour when the confining pressure of the air is removed; and this vapour, by its elasticity, exerts a small pressure on the surface of the water, &c. in the pipe, and thus counteracts a small part of the external pressure; and therefore the column supported by the remaining pressure must be lighter, that is, shorter. Thus it is found, that rectified spirits will not stand much higher than is competent to a weight of 13 pounds on an inch, the elasticity of its vapour balancing about $\frac{1}{13}$ of the pressure of the air. We shall afterwards have occasion to consider this matter more particularly.

A difficulty solved.

As the medium height of the mercury in the barometer is $29\frac{1}{2}$ inches, we see that the whole globe sustains a pressure equal to the whole weight of a body of mercury of this height; and that all bodies on its surface sustain a part of this in proportion to their surfaces. An ordinary sized man sustains a pressure of several thousand pounds. How comes it then that we are not sensible of a pressure which one should think enough to crush us together? This has been considered as a strong objection to the pressure of the air; for when a man is plunged a few feet under water, he is very sensible of the pressure. The answer is by no means so easy as is commonly imagined. We feel very distinctly the effects of removing this pressure from any part of the body. If any one will apply the open end of a syringe to his hand, and then draw up the piston, he will find his hand sucked into the syringe with great force, and it will give pain; and the soft part of the hand will swell into it, being pressed in by the neighbouring parts, which are subject to the action of the external air. If one lays his hand on the top of a long perpendicular pipe, such as a pump filled to the brim with water, which is at first prevented from running out by the valve below; and if the valve be then opened, so that the water descends, he will then find his hand so hard pressed to the top of the pipe, that he cannot draw it away. But why do we only feel the *inequality* of pressure? There is a similar instance wherein we do not feel it, although we cannot doubt of its existence. When a man goes slowly to a great depth under water in a diving-bell, we know unquestionably that he is exposed to a new and very great pressure, yet he does not feel it. But those facts are not sufficiently familiar for general argument. The human body is a bundle of solids, hard or soft, filled or mixed with fluids, and there are few or no parts of it which are empty. All communicate either by vessels or pores; and the whole surface is a sieve through which the insensible perspiration is performed. The whole extended surface of the lungs is open to the pressure of the atmosphere; every thing is therefore in equilibrio; and if free or speedy access be given to every part, the body will not be damaged by the pressure, however great, any more than a wet sponge would be deranged by plunging it any depth in water. The pressure is instantaneously diffused by means of the incompressible fluids with which the parts are filled; and if any parts are filled with air or other compressible fluids, these are compressed till their elasticity again balances the pressure. Besides, all our fluids are acquired slowly, and gradually mixed with that proportion of air which they can dissolve or contain. The whole animal has grown up in this manner from the first vital atom of the embryo. For such reasons the pressure can occasion no change of shape by squeezing together the flexible parts; nor any obstruction by compressing the vessels or pores. We cannot say what would be felt by a man, were it possible that he could have been produced and grown up *in vacuo*, and then subjected to the compression. We even know that any sudden and considerable change of general pressure is very severely felt. Persons in a diving-bell have been almost killed by letting them down or drawing them up too suddenly. In drawing up, the elastic matters within have suddenly swelled, and not finding an immediate escape, have burst the vessels. Dr. Halley experienced this, the blood gushing out from his ears by the expansion of air contained in the internal cavities of this organ, from which there are but very slender passages.

The weather-glass.

A very important observation recurs here. The pressure of the atmosphere is variable. This was observed almost as soon as philosophers began to attend to the barometer. Pascal observed it in France, and Descartes observed it in Sweden in 1650. Mr. Boyle and others observed it in England in 1656. And before this, observers, who took notice of the concomitancy of these changes of aerial pressure with the state of the atmosphere, remarked, that it was generally greatest in winter and in the night; and certainly most variable during winter and in the northern regions. Familiar now with the weight of the air, and considering it as the vehicle of the clouds and vapours, they noted with care the connection between the weather and the pressure of the air, and found that a great pressure of the air was generally accompanied with fair weather, and a diminution of it with rain and mists. Hence the barometer came to be considered as an index not only of the present state of the air's weight, but also as indicating by its variations changes of weather.

The pressure of the air in proportion to the elevation.

In the next place, we may conclude that the pressure of the air will be different in different places, according to their elevation above the surface of the ocean; for if air be a heavy fluid, it must press in some proportion according to its perpendicular height. If it be a homogeneous fluid of equal density and weight in all its parts, the mercury in the cistern of a barometer must be pressed precisely in proportion to the depth to which that cistern is immersed in it; and as this pressure is exactly measured by the height of the mercury in the tube, the height of the mercury in the Toricellian tube must be exactly proportional to the depth of the place of observation under the surface of the atmosphere.

This proved by experiments.

The celebrated Descartes first entertained this thought, (Epist. 67. of Pr. III.) and soon after him Pascal. His occupation in Paris not permitting him to try the justness of his conjecture, he requested Mr. Perrier, a gentleman of Clermont in Auvergne, to make the experiment, by observing the height of the mercury at one and the same time at Clermont and on the top of a very high mountain in the neighbourhood. His letters to Mr. Perrier in 1647 are still extant. Accordingly, Mr. Perrier, in September 1648, filled two equal tubes with mercury, and observed the heights of both to be the same, viz. 26$\frac{7}{24}$ inches, in the garden of the convent of the Friars Minims, situated in the lowest part of Clermont. Leaving one of them there, and one of the fathers to observe it, he took the other to the top of Puy de Dome, which was elevated nearly 500 French fathoms above the garden. He found its height to be 23$\frac{2}{24}$ inches. On his return to the town, in a place called *Font de l'Arbre*, 150 fathoms above the garden, he found it 25 inches; when he returned to the garden it was again 26$\frac{7}{24}$, and the person set to watch the tube which had been left, said that it had not varied the whole day. Thus a difference of elevation of 3000 French feet had occasioned a depression of 3$\frac{1}{8}$ inches; from which it may be concluded, that 3$\frac{1}{8}$ inches of mercury weighs as much as 3000 feet of air, and one-tenth of an inch of mercury as much as 96 feet of air. The next day he found, that taking the tube to the top of a steeple 120 feet high, made a fall of one-sixth of an inch. This gives 72 feet of air for one-tenth of an inch of mercury; but ill agreeing with the former experiment. But it is to be observed, that a very small error of observation of the barometer would correspond to a great difference of elevation, and also that the height of the mountain had not been measured with any precision. This has been since done (Mem. Acad. par. 1703,) and found to be 529 French toises.

Pascal published an account of this great experiment,[1] and it was quickly repeated in many places of the world. In 1653, it was repeated in England by Dr. Power (Power's Exper. Phil.) and in Scotland in 1661, by Mr. Sinclair, professor of philosophy in the university of Glasgow, who observed the barometer at Lanark, on the top of mount Tinto in Clydesdale, and on the top of Arthur's seat at Edinburgh. He found a depression of two inches between Glasgow and the top of Tinto, three quarters of an inch between the bottom and top of Arthur's seat, and $\frac{5}{32}$ of an inch at the cathedral of Glasgow on a height of 126 feet.[2]

Hence a method of measuring heights.

Hence we may derive a method of measuring the heights of mountains. Having ascertained with great precision the elevation corresponding to a fall of one-tenth of an inch of mercury, which is nearly 90 feet, we have only to observe the length of the mercurial column at the top and bottom of the mountain, and to allow 90 feet for every tenth of an inch. Accordingly this method has been practised with great success; but it requires an attention to many things not yet considered; such as the change of density of the mercury by heat and cold; the changes of density of air from its compressibility; a change immediately connected with or dependent on the very elevation we wish to measure.

Also a measure of the density of the air.

These observations give us the most accurate measure of the density of air and its specific gravity. This is but vaguely though directly measured by weighing air in a bladder or vessel. The weight of a manageable quantity is so small, that a balance sufficiently ticklish to indicate even very sensible fractions of it is overloaded by the weight of the vessel which contains it, and ceases to be exact; and when we take Bernouilli's ingenious method of suspending it in water, we expose ourselves to great risk of error by the variation of the water's density. Also it must necessarily be humid air which we can examine in this way: but the proportion of an elevation in the atmosphere to the depression of the column of mercury or other fluid, by which we measure its pressure, gives us at once the proportion of this weight or their specific gravity. Thus since it is found that in such a state of pressure the barometer stands at 30 inches, and the thermometer at 32°, 87 feet of rise produces one-tenth of an inch of fall in the barometer, the air and the mercury being both of the freezing temperature, we must conclude that mercury is 10,440 times heavier or denser than air. Then, by comparing mercury and water, we get $\frac{1}{800}$ nearly for the density of air relative to water; but this varies so much by heat and moisture, that it is useless to retain any thing more than a general notion of it; nor is it easy to determine whether this method or that by actual weighing be preferable. It is extremely difficult to observe the height of the mercury in the barometer nearer than $\frac{1}{200}$ of an inch; and this will produce a difference of even five feet, or $\frac{1}{20}$ of the whole. Perhaps this is a greater proportion than the error in weighing.[3]

Height of the atmosphere.

From the same experiments we also derive some knowledge of the height of the aerial covering which surrounds our globe. When we raise our barometer 87 feet above the surface of the sea, the mercury falls about one-tenth of an inch in the barometer; therefore if the barometer shows 30 inches at the sea-shore, we may expect that, by raising it 300 times 87 feet or five miles, the mercury in the tube will descend to the level of the cistern, and that this is the height of our atmosphere. But other appearances lead us to suppose a much greater height. Meteors are seen with us much higher than this, and which yet give undoubted indication of being supported by our air. There can be little doubt, too, that the visibility of the expanse above us is owing to the reflection of the sun's light by our air. Were the heavenly spaces perfectly transparent, we should no more see them than the purest water through which we see other objects; and we see them as we see water tinged with milk or other fæculæ. Now it is easy to show, that the light which gives us what is called twilight must be reflected from the height of at least 50 miles; for we have it when the sun is depressed 18 degrees below our horizon.

Why this knowledge is not accurate.

A little attention to the constitution of our air will convince us, that the atmosphere must extend to a much greater height than 300 times 87 feet. We see from the most familiar facts that it is compressible; we can squeeze it in an ox-bladder. It is also heavy; pressing on the air in this bladder with a very great force, not less than 1500 pounds. We must therefore consider it as in a state of compression, existing in smaller room than it would assume if it were not compressed by the incumbent air. It must therefore be in a condition something resembling that of a quantity of fine carded wool thrown loosely into a deep pit; the lower strata carrying the weight of the upper strata, and being compressed by them; and so much the more compressed as they are further down, and only the upper stratum in its unconstrained and most expanded state. If we shall suppose this wool thrown in by a hundred weight at a time, it will be divided into strata of equal weights, but of unequal thickness; the lowest being the thinnest, and the superior strata gradually increasing in thickness. Now, suppose the pit filled with air, and reaching to the top of the atmosphere, the weights of all the strata above any horizontal plane in it is measured by the height of the mercury in the Toricellian tube placed in that plane; and one-tenth of an inch of mercury is just equal to the weight of the lowest stratum 87 feet thick; for on raising the tube 87 feet from the sea, the surface of the mercury will descend one-tenth of an inch. Raise the tube till the mercury fall another tenth. This stratum must be more than 87 feet thick: how much more we cannot tell, being ignorant of the law of the air's expansion. In order to make it fall a third tenth, we must raise it through a stratum still thicker; and so on continually.

[3] Barometers are now made by which accurate observations may be made to the $\frac{1}{1000}$th part of an inch.

All this is abundantly confirmed by the very first experiment made by the order and directions of Pascal. For by carrying the tube from the garden of the convent to a place 150 fathoms higher, the mercury fell $\frac{7}{24}$ inches, or 1.2916; which gives about 69 feet eight inches of aerial stratum for $\frac{1}{10}$ of an inch of mercury; and by carrying it from thence to a place 350 fathoms higher, the mercury fell $1\frac{22}{24}$, or 1.9167 inches, which gives 109 feet seven inches for $\frac{1}{10}$ of an inch of mercury. These experiments were not accurately made. It is evident, however, from the whole tenor of them, that the strata of air decrease in density as we ascend through the atmosphere; but it remained to be discovered what is the force of this decrease, that is, the law of the air's expansion. Till this be done we can say nothing about the constitution of our atmosphere; we cannot tell in what manner it is fittest for raising and supporting the exhalations and vapours which are continually arising from the inhabited regions; not as an excrementitious waste, but to be supported, perhaps manufactured, in that vast laboratory of nature, and to be returned to us in beneficent showers. We cannot use our knowledge for the curious, and frequently useful, purpose of measuring the heights of mountains and taking the levels of extensive regions; in short, without an accurate knowledge of this, we can hardly acquire any acquaintance with those mechanical properties which distinguish air from those liquids which circulate here below.

Compressibility of the air.

Having therefore considered at some length the leading consequences of the air's fluidity and gravity, let us consider its compressibility with the same care; and then, combining the agency of both, we shall answer all the purposes of philosophy, discover the laws, explain the phenomena of nature, and improve art. We proceed therefore to consider a little the phenomena which indicate and characterise this other property of the air. All fluids are elastic and compressible as well as air; but in them the compressibility makes no figure, or does not interest us while we are considering their pressures, motions, and impulsions. But in air the compressibility and expansion draw our chief attention, and make it a proper representative of this class of fluids.

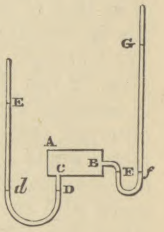
A familiar phenomenon.

Nothing is more familiar than the compressibility of air. It is seen in a bladder filled with it, which we can forcibly squeeze into less room; it is seen in a syringe, of which we can push the plug farther and farther as we increase the pressure. But these appearances bring into view another, and the most interesting, property of air, viz. its *elasticity*. When we have squeezed the air in the bladder or syringe into less room, we find that the force with which we *compressed* it is necessary to *keep it in this bulk;* and that if we cease to press it together, it will swell out and regain its natural dimensions. This distinguishes it essentially from such a body as a mass of flour, salt, or such like, which remain in the compressed state to which we reduce them. There is something therefore which opposes the compression different from the simple impenetrability of the air: there is something that opposes mechanical force: there is something too which produces motion, not only resisting compression, but pushing back the compressing body, and communicating motion to it. As an arrow is gradually accelerated by the bow-string pressing it forward, and at the moment of its discharge is brought to a state of rapid motion; so the ball from a pop-gun or wind-gun is gradually accelerated along the barrel by the pressure of the air during its expansion from its compressed state, and finally quits it with an accumulated velocity. These two motions are indications perfectly similar of the elasticity of the bow and of the air.

Fluidity of the air experimentally proved

Thus it appears that air is heavy and elastic. It needs little consideration to convince us in a vague manner that it is fluid. The ease with which it is penetrated, and driven about in every direction, and the motion of its pipes and channels, however crooked and intricate, entitle it to this character. But before we can proceed to deduce consequences from its fluidity, and to offer them as a true account of what will happen in these circumstances, it is necessary to exhibit some distinct and simple case, in which the characteristic mechanical property of a fluid is clearly and unequivocally observed in it. That property of fluids is, that any pressure applied to any part of them is propagated through the whole mass in every direction; and that in consequence of this diffusion of pressure, any two external forces can be put in equilibrio by the interposition of a fluid, in the same way as they can be put in equilibrio by the intervention of any mechanical engine.

Fig. 7.



Let a close vessel ABC (fig. 7.), of any form, have two upright pipes EDC, GFB, inserted into any parts of its top, sides, or bottom, and let water be poured into them, so as to stand in equilibrio with the horizontal surfaces at E, D, G, F, and let D *d*, F *f*, be horizontal lines, *it will be found* that the height of the column E *d* is sensibly equal to that of the column G *f*. This is a fact universally observed in whatever way the pipes are inserted. Now the surface of the water at D is undoubtedly pressed upwards with a force equal to a column of water, having its surface for its base, and E *d* for its height; it is therefore prevented from rising by some opposite force. This can be nothing but the elasticity of the confined air pressing it down. The very same thing must be said of the surface at F; and thus there are two external pressures at D and F set in equilibrio by the interposition of air. The force exerted on the surface D, by the pressure of the column E *d*, is therefore propagated to the surface at F; and thus air has this characteristic mark of fluidity.

In this experiment the weight of the air is insensible when the vessel is of small size, and has no sensible share in the pressure reaching at D and F. But if the elevation of the point F above D is very great, the column E *d will be observed* sensibly to exceed the column G *f*. Thus if F be 70 feet higher than D, E *d* will be an inch longer than the column G *f*: for in this case there is reacting at D, not only the pressure propagated from F, but also the weight of a column of air, having the surface at D for its base and 70 feet high. This is equal to the weight of a column of water one inch high.

It is by this propagation of pressure, this *fluidity*, that the pellet is discharged from a child's pop-gun. It sticks fast in the muzzle; and he forces in another pellet at the other end, which he presses forward with the rammer, condensing the air between them, and thus propagating to the other pellet the pressure which he exerts, till the friction is overcome, and the pellet is discharged by the air expanding and following it.

Hero's fountain.

There is a philosophical toy which illustrates this property of air, and which we shall have occasion to consider as converted into a useful hydraulic machine. This is what is usually called *Hero's fountain*. It consists of two vessels KLMN (fig. 8.), OPQR, which are close on all sides. The tube AB, having a funnel a-top, passes through the uppermost vessel without communicating with it, being soldered into its top and bottom. It also passes through the top of the under-vessel, where it is also soldered, and reaches almost to its bottom. This tube is open at both ends. There is another open tube ST, which is soldered into the top of the under vessel and the bottom of the upper vessel, and reaches almost to its top. These two tubes serve also to support the upper vessel. A third tube GF is soldered into the top of the upper vessel, and reaches almost to its bottom. This tube is open at both ends, but the orifice G is very small. Now suppose the uppermost vessel filled with water to the height EN, E *e* being its surface a little below T. Stop the orifice G with the finger, and pour in water at A. This will descend through AB, and compress the air in OPQR into less room. Suppose the water in the under vessel to have acquired the surface C *c*, the air which formerly occupied the whole of the spaces OPQR, and KL*e*E will now be contained in the spaces *o* P *c* C and KL *e* E; and its elasticity will be in equilibrio with the weight of the column of water, whose base is the surface E *e*, and whose height is A *c*. As this pressure is exerted in every part of the air, it will be exerted on the surface E *e* of the water of the upper vessel; and if the pipe FG were continued upwards, the water would be supported in it to an height *e* H above E *e*, equal to A *c*. Therefore if the finger be now taken from off the orifice G, the water will spout up to the same height as if it had been immediately forced out by a column of water A *c* without the intervention of the air, that is, nearly to H. If instead of the funnel at A, the vessel have a brim VW which will cause the water discharged at G to run down the pipe AB, this fountain will play till all the water in the upper vessel is expended. The operation of this second fountain will be better understood from fig. 9, which an intelligent reader will see is perfectly equivalent to fig. 8. A very powerful engine for raising water upon this principle has long been employed in the Hungarian mines; where the pipe AB is about 200 feet high, and the pipe FG about 120; and the condensation is made in the upper vessel, and communicated to the lower at the bottom of the mine, by a long pipe.

Fig. 8.

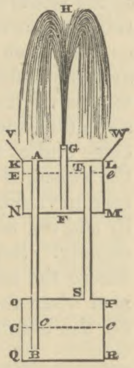


Fig. 9.

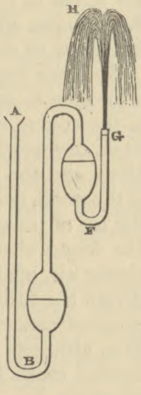


Laws of hydrostatics applicable to air.

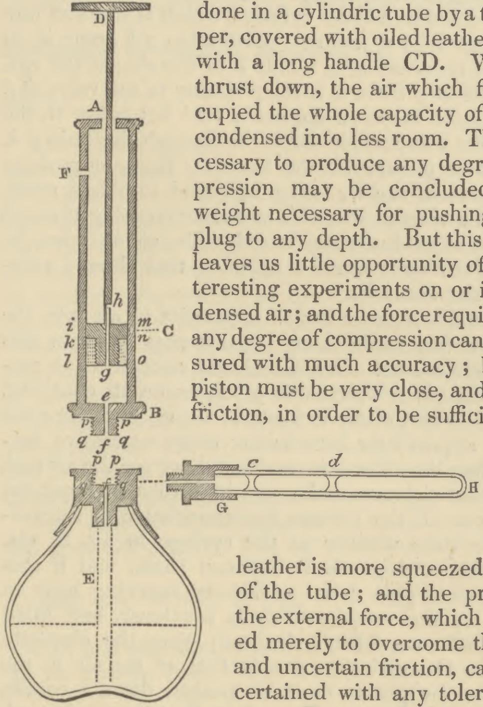
We may now then apply to air the laws of hydrostatics and hydraulics, in perfect confidence that their legitimate consequences will be observed in all its situations. We shall in future substitute, in place of any force acting on a surface of air, a column of water, mercury, or any other fluid whose weight is equal to this force; and as we know distinctly from theory what will be the consequences of this hydrostatic pressure, we shall determine *a priori* the phenomena in air; and in cases where theory does not enable us to say with precision what is the effect of this pressure, experience informs us in the case of water, and analogy enables us to transfer this to air.

More refined experiments.

From such familiar and simple observations and experiments, the fluidity, the heaviness, and elasticity, are discovered of the substance with which we are surrounded, and which we call *air*. But to understand these properties, and completely to explain their numerous and important consequences, we must call in the aid of more refined observations and experiments, which even this scanty knowledge of them enables us to make; we must contrive some methods of producing with precision, any degree of condensation or rarefaction, of employing or excluding the gravitating pressure of air, and of modifying at pleasure the action of all its mechanical properties.

Nothing can be more obvious than a method of compressing a quantity of air to any degree. Take a cylinder or prismatic tube AB (fig. 10.) shut at one end, and fit it with a piston or plug C, so nicely that no air can pass by its sides. This will be best done in a cylindric tube by a turned stopper, covered with oiled leather, and fitted with a long handle CD. When this is thrust down, the air which formerly occupied the whole capacity of the tube is condensed into less room. The force necessary to produce any degree of compression may be concluded from the weight necessary for pushing down the plug to any depth. But this instrument leaves us little opportunity of making interesting experiments on or in this condensed air; and the force required to make any degree of compression cannot be measured with much accuracy; because the piston must be very close, and have great friction, in order to be sufficiently tight. And as the compression is increased, the leather is more squeezed to the side of the tube; and the proportion of the external force, which is employed merely to overcome this variable and uncertain friction, cannot be ascertained with any tolerable precision. To get rid of these imperfections, the following addition may be made to the instrument, which then becomes what is called the condensing syringe.

Fig. 10.



The end of the syringe is perforated with a very small hole *e f*, and being externally turned to a small cylinder, a narrow slip of bladder, or of waxed silk, must be tied over the hole at *f*. Now let us suppose the piston pushed down to the bottom of the barrel, to which it applies close; when it is drawn up to the top, it leaves a void behind, and the weight of the external air presses on the slip of bladder, which therefore clasps close to the brass, and thus performs the part of a valve, and keeps it close, so that no air can enter. But the piston having reached the top of the barrel, a hole F in the side of it is just below the piston, and the air rushes through this hole, and fills the barrel. Now push the piston down again, it immediately passes the hole F, and no air escapes through it; it therefore forces open the valve at *f*, and escapes while the piston moves to the bottom.

Now let E be any vessel, such as a glass bottle, having its mouth furnished with a brass cap firmly cemented to it, having a hollow screw which fits a solid screw *p p*, turned to the cylindric nozzle of the syringe. Screw the syringe into this cap, and it is evident that the air forced out of the syringe will be accumulated in this vessel; for upon drawing up the piston, the valve *f* always shuts by the elasticity or expanding force of the air in E; and on pushing it down again, the valve will open as soon as the piston has got so far down that the air in the lower part of the barrel is more powerful than the air already in the vessel. Thus at every stroke an additional barrelful of air will be forced into the vessel E; and it will be found, that after every stroke the piston must be farther pushed down before the valve will open. It cannot open till the pressure arising from the elasticity of the air condensed in the barrel, is superior to the elasticity of the air condensed in the vessel; that is, till the condensation of the first, or its density, is *somewhat* greater than that of the last, in order to overcome the straining of the valve on the hole, and the sticking occasioned by the clammy matter employed to make it air-tight.

Sometimes the syringe is constructed with a valve in the piston. This piston, instead of being of one piece, and solid, consists of two pieces perforated. The upper part *i k n m*, is connected with the rod or handle, and has its lower part turned down to a small cylinder, which is screwed into the lower part *k l o n*, and as a perforation *g h* going up in the axis, and terminating in a hole *h* in one side of the rod, over this hole at *g* there is a valve similar to the valve at *f*. When the piston is drawn up, and a void left below it, the weight of the external air forces it through the hole *g h*, opens the valve *g*, and fills the barrel. Then, on pushing down the piston, the air being squeezed into less room, presses on the valve *g*, shuts it; and none escaping through the piston, it is gradually condensed as the piston descends, till it opens the valve *f*, and is added to that already accumulated in the vessel E.

Elasticity of the air increased by condensation.

Having in this manner forced a quantity of air into the vessel E, we can make many experiments in it in this state of condensation. We are chiefly concerned at present, with the effect which this produces on its elasticity. We see this to be greatly increased; for we find more and more force required for introducing every successive barrelful. When the syringe is unscrewed, we see the air rush out with great violence, and every indication of great expanding force. If the syringe be connected with the vessel E, in the same manner as the syringe in fig. 3, viz. by interposing a stopcock B between them, and if this stopcock have a pipe at its extremity, reaching near to the bottom of the vessel, which is previously half filled with water, we can observe distinctly when the elasticity of the air in the syringe exceeds that of the air in the receiver; for the piston must be pushed down a certain length before the air from the syringe bubbles up through the water, and the piston must be farther down at each successive stroke before this appearance is observed. When the air has thus been accumulated in the receiver, it presses the sides of it outward, and will burst it if not strong enough. It also presses on the surface of the water; and if we now shut the cock, unscrew the syringe, and open the cock again, the air will force the water through the pipe with great velocity, causing it to rise in a beautiful jet. When a metal-receiver is used, the condensation may be pushed to a great length, and the jet will then rise to a great height; which gradually diminishes as the water is expended, and room given to the air to expand itself.

Methods of judging of the condensation, &c.

We judge of the condensation of air in the vessel E, by the number of strokes, and the proportion of the capacity of the syringe to that of the vessel. Suppose the first to be one-tenth of the last; then we know, that after ten strokes the quantity of air in the vessel is doubled, and therefore its density double, and so on after any number of strokes. Let the capacity of the syringe (when the piston is drawn to the top) be *a*, and that of the vessel be *b*, and the number of strokes be *n*, the density of air in the vessel will be $\frac{b+na}{b}$, or $1+\frac{na}{b}$.

But this is on the supposition that the piston accurately fills the barrel, the bottom of the one applying close to that of the other, and that no force is necessary for opening either of the valves; but the first cannot be insured, and the last is very far from being true. In the construction now described, it will require at least one-twentieth part of the ordinary pressure of the air to open the piston valve; therefore the air which gets in will want at least this proportion of its complete elasticity; and there is always a similar part of the elasticity employed in opening the nozzle valve. The condensation therefore is never nearly equal to what is here determined.

It is accurately enough measured by a gage fitted to the instrument. A glass tube GH of a cylindric bore, and close at the end, is screwed into the side of the cap on the mouth of the vessel E. A small drop of mercury is taken into this tube by warming it a little in the hand, which expands the contained air, so that when the open end is dipped into mercury, and the whole allowed to cool, the mercury advances a little into the tube. The tube is furnished with a scale divided into small equal parts, numbered from the close end of the tube. Since this tube communicates with the vessel, it is evident that the condensation will force the mercury along the tube, acting like a piston on the air beyond it, and the air in the tube and vessel will always be of one density. Suppose the number at which the drop stands before the condensation is made to be *c*, and that it stands at *d* when the condensation has attained the degree required, the density of the air in the remote end of the gage, and consequently in the vessel, will be $\frac{c}{d}$.

Sometimes there is used any bit of tube close at one end, having a drop of mercury in it, simply laid into the vessel E, and furnished with a scale; but this can only be used with glass vessels, and these are with difficulty made strong enough to resist the pressure arising from great condensation. In such experiments metalline vessels are generally used, fitted with a variety of apparatus for different experiments.

Syringes for great condensations.

It must be observed in this place, that very great condensations require great force, and therefore small syringes. It is therefore convenient to have them of various sizes, and to begin with those of a larger diameter, which operate more quickly; and when the condensation becomes fatiguing, to change the syringe for a smaller.

For this reason, and in general to make the condensing apparatus more convenient, it is proper to have a stop-cock interposed between the syringe and the vessel, or, as it is usually called, the receiver. This consists of a brass pipe, which has a well-ground cock in its middle, and has a hollow screw at one end, which receives the nozzle screw of the syringe, and a solid screw at the other end, which fits the screw of the receiver. (See fig. 3.)

Instances of great condensation.

By these gages, or contrivances similar to them, we have been able to ascertain very great degrees of condensation in the course of some experiments. Dr. Hales found, that when dry wood was put into a strong vessel, which it almost filled, and the remainder was filled with water, the swelling of the wood, occasioned by its imbibition of water, condensed the air of his gage into the thousandth of its original bulk. He found that pease, treated in the same way, generated elastic air, which, pressing on the air in the gage, condensed it into the fifteen-hundredth part of its bulk. This is the greatest condensation that has been ascertained with precision, although in other experiments it has certainly been carried much farther; but the precise degree could not be ascertained.

Some opinions respecting elasticity, &c.

Another important observation is, that in every state of density in which we find it, it retains its perfect fluidity, transmitting all pressures which are applied to it with undiminished force, as appears by the equality constantly observed between the opposing columns of water or other fluid by which it is compressed, and by the facility with which all motions are performed in it in the most compressed states in which we can make observations of this kind. This fact is totally incompatible with the opinion of those who ascribe the elasticity of air to the springy ramified structure of its particles, touching each other like so many pieces of sponge or foot-balls. A collection of such particles might indeed be pervaded by solid bodies with considerable ease, if they were merely touching each other, and not subjected to any external pressure. But the moment such pressure is exerted, and the assemblage squeezed into a smaller space, each presses on its adjoining particles: they are individually compressed, flattened in their touching surfaces, and before the density is doubled they are squeezed into the form of perfect tubes, and compose a mass, which may indeed propagate pressure from one place to another in an imperfect manner, and with great diminution of its intensity, but will no more be fluid than a mass of soft clay.

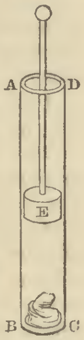
Consequences of the air's elasticity.

We have seen the air is heavy and compressible, and might now proceed to deduce in order the explanation of the appearances consequent on each of these properties. But, as has been already observed, the elasticity of air modifies the effects of its gravity so remarkably, that they would be imperfectly understood if both qualities were not combined in our consideration of either. At any rate, some farther consequences of its elasticity must be considered, before we understand the means of varying at pleasure the effects of its gravity.

Its great expansibility proved by experiment.

Since air is heavy, the lower strata of a mass of air must support the upper; and, being compressible, they must be condensed by their weight. In this state of compression the elasticity of the lower strata of air acts in opposition to the weight of the incumbent air, and balances it. There is no reason which should make us suppose that its expanding force belongs to it only when in such a state of compression. It is more probable that, if we could free it from this pressure, the air would expand itself into still greater bulk. This is most distinctly seen in the following experiment.

Fig. 11.

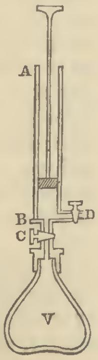


Into the cylindric jar ABCD, (fig. 11,) which has a small hole in its bottom, and is furnished with an air-tight piston E, put a small flaccid bladder, having its mouth tied tight with a string. Having pushed the piston near to the bottom, and noticed the state of the bladder, stop up the hole in the bottom of the jar with the finger, and draw up the piston, which will require a considerable force. You will observe the bladder swell out, as if air had been blown into it; and it will again collapse on allowing the piston to descend. Nothing can be more unexceptionable than the conclusion from this experiment, that ordinary air is in a state of compression, and that its elasticity is not limited to this state. The bladder being flaccid, shews that the included air is in the same state with the air which surrounds it; and the same must be affirmed of it while it swells but still remains flaccid. We must conclude that the whole air within the vessel expands, and continues to fill it, when its capacity has been enlarged. And since this is observed to go on as long as we give it more room, we conclude, that by such experiments we have not yet given it so much room as it can occupy.

Attempts to discover the limits of this expansion.

It was a natural object of curiosity to discover the limits of this expansion; to know what was the natural unconstrained bulk of a quantity of air, beyond which it would not expand though all external compressing force were removed. Accordingly philosophers constructed instruments for *rarefying* the air. The common water-pump had been long familiar, and appeared very proper for this purpose. The most obvious is the following.

Fig. 12.



Let the barrel of the syringe AB communicate with the vessel V, with a stopcock C between them. Let it communicate with the external air by another orifice D, in any convenient situation, also furnished with a stopcock. Let this syringe have a piston very accurately fitted to it so as to touch the bottom all over when pushed down, and have no vacancy about the sides.

Now, suppose the piston at the bottom, the cock C open, and the cock D shut, draw the piston to the top. The air which filled the vessel V will expand so as to fill both that vessel and the barrel AB; and, as no reason can be given to the contrary, we must suppose that the air will be uniformly diffused through both. Calling V and B the capacity of the vessel and barrel, it is plain that the bulk of the air will now be $V+B$; and since the quantity of matter remains the same, and the density of a fluid is as its quantity of matter directly and its bulk inversely, the density of the expanded air will be $\frac{V}{V+B}$, the density of common air being 1; for $V+B : V = 1 : \frac{V}{V+B}$.

The piston requires force to raise it, and it is raised in opposition to the pressure of the incumbent atmosphere; for this had formerly been balanced by the elasticity of the common air; and we conclude from the fact, *that force is required to raise the piston*, that the elasticity of the expanded air is less than that of air in its ordinary state; and an accurate observation of the force necessary to raise it would shew how much the elasticity is diminished. When therefore the piston is let go, it will descend as long as the pressure of the atmosphere exceeds the elasticity of the air in the barrel; that is, till the air in the barrel is in a state of ordinary density. To put it further down will require force, because the air must be compressed in the barrel; but if we open the cock D, the air will be expelled through it, and the piston will reach the bottom.

Now shut the *discharging cock* D, and open the cock C, and draw the piston. The air which occupied the space V, with the density $\frac{V}{V+B}$, will now occupy the space $V+B$, if it expands so far. To have its density D, say, As its present bulk $V+B$ is to its former bulk V, so its former density $\frac{V}{V+B}$ to its new density; which will therefore be $\frac{V\times V}{\overline{V+B}\times\overline{V+B}}$, or $\overline{\frac{V}{V+B}}\Big|^{2}$.

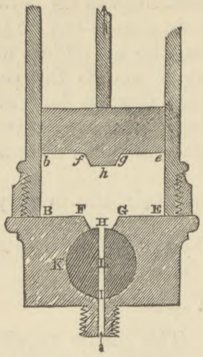
It is evident, that if the air continues to expand, the density of the air in the vessel after the third drawing up of the piston will be $\overline{\frac{V}{V+B}}\Big|^{3}$, after the fourth it will be $\overline{\frac{V}{V+B}}\Big|^{4}$, and after any number of strokes n will be $\overline{\frac{V}{V+B}}\Big|^{n}$. Thus, if the vessel is four times as large as the barrel, the density after the fifth stroke will be $\frac{1024}{3125}$, nearly $\frac{1}{3}$ of its ordinary density.

On the other hand, the number n of strokes necessary for reducing air to the density D is $\frac{\log D}{\log V - \log \overline{(V+B)}}$.

Some inconveniences of this instrument.

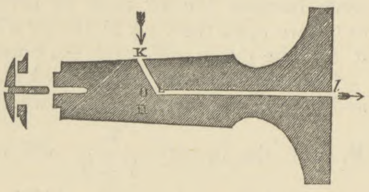
Thus we see that this instrument can never abstract the whole air in consequence of its expansion, but only rarefy it continually as long as it continues to expand; nay, there is a limit beyond which the rarefaction cannot go. When the piston has reached the bottom, there remains a small space between it and the cock C filled with common air. When the piston is drawn up, this small quantity of air expands, and also a similar quantity in the neck of the other cock; and no air will come out of the receiver V till the expanded air in the barrel is of a smaller density than the air in the receiver. This circumstance evidently directs us to make these two spaces as small as possible, or by some contrivance to fill them up altogether. Perhaps this may be done effectually in the following manner.

Fig. 13.



Let BE represent the bottom of the barrel, and let the circle HKI be the section of the key of the cock, of a large diameter, and place it as near to the barrel as can be. Let this communicate with the barrel by means of a hole FG widening upwards, as the frustum of a hollow obtuse cone. Let the bottom of the piston *b f h g e* be shaped so as to fit the bottom of the barrel and this hole exactly. Let the cock be pierced with two holes. One of them, HI, passes perpendicularly through its axis, and forms the communication between the receiver and barrel. The other hole, KL, has one extremity K on the same circumference with H, so that when the key is turned a fourth part round, K will come into the place of H: but this hole is pierced obliquely into the key, and thus keeps clear of the hole HI. It goes no further than the axis, where it communicates with a hole bored along the axis and terminating at its extremity. This hole forms the communication with the external air, and serves for discharging the air in the barrel.

Fig. 14.



(A side view of the key is seen in fig. 14.) Fig. 13 shows the position of the cock while the piston is moving upwards, and fig. 14 shows its position while the piston is moving downwards. When the piston has reached the bottom, the conical piece *f h g* of the piston, which may be of firm leather, fills the hole FHG, and therefore completely expels the air from the barrel. The canal KL *l* of the cock contains air of the common density; but this is turned aside into the position KL (fig. 13), while the piston is still touching the cock. It cannot extend into the barrel during the ascent of the piston. In place of it the perforation HLI comes under the piston, filled with air that had been turned aside with it when the piston was at the top of the barrel, and therefore of the same density with the air of the receiver. It appears therefore that there is no limit to the rarefaction as long as the air will expand.

This instrument is called an Exhausting Syringe. It is more generally made in another form, which is much less expensive, and more convenient in its use. Instead of being furnished with *cocks* for establishing the communications and shutting them, as is necessary, it has *valves* like those of the condensing syringe, but opening in the opposite direction from those in fig. 10.

This syringe is evidently more easy in its use, requiring no attention to the cocks to open and shut them at the proper times. On this account this construction of an exhausting syringe is much more generally used.

But it is greatly inferior to the syringe with cocks, with respect to its power of rarefaction. It is evident that no air will come out of the receiver unless its elasticity *exceed* that of the air in the barrel by a difference able to lift up the valve fig. 10. A piece of waxed silk tied across this hole can hardly be made tight and certain of clapping to the hole without some small straining, which must therefore be overcome. It must be very gentle indeed not to require a force equal to the weight of two inches of water, and this is equal to about the 200th part of the whole elasticity of the ordinary air; and therefore this syringe, for this reason alone, cannot rarefy air above 200 times, even though air were capable of an indefinite expansion. In like manner the valve in the piston cannot be raised without a similar prevalence of the elasticity of the air in the barrel above the weight of the atmosphere. These causes united, make it difficult to rarefy the air more than 100 times, and very few such syringes will rarefy it more than 50 times; whereas the syringe with cocks, when new and in good order, will rarefy it 1000 times.

But, on the other hand, syringes with cocks are much more expensive, especially when furnished with apparatus for opening and shutting the cocks. They are more difficult to make equally tight, and (which is the greatest objection) do not remain long in good order. The cocks, by so frequently opening and shutting, grow loose, and allow the air to escape. No method has been found of preventing this. They must be ground tight by means of emery or other cutting powders. Some of these unavoidably stick in the metal, and continue to wear it down. For this reason philosophers, and the makers of philosophical instruments, have turned their chief attention to the improvement of the syringe with valves.

OF THE AIR-PUMP.

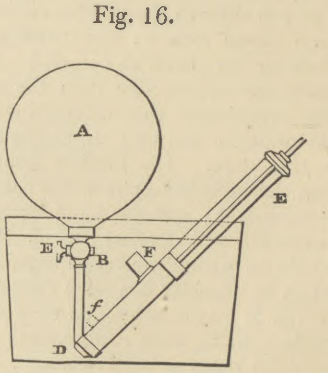
Invention of the air-pump by Guericke.

An Air-Pump is nothing but an exhausting syringe accommodated to a variety of experiments. It was first invented by Otto Guericke, a gentleman of Magdeburgh in Germany, about the year 1654. We trust that it will not be unacceptable to our readers to see this instrument in its first form, and to trace it through its successive steps to its present state of improvement.

Guericke gave a minute description of all his pneumatic apparatus to Gaspar Schottus, professor of mathematics at Wirtemberg, who immediately published it with the author's consent, with an account of some of his performances, first in 1657, in his *Mechanica Hydraulico-pneumatica;* and then in his *Technica Curiosa,* in 1664.

Construction of his pump.

Fig. 16.



Otto Guericke's air-pump consists of a glass receiver A of a form nearly spherical, fitted up with a brass cap and cock B. The nozzle of the cap was fixed to a syringe DE, also of brass, bent at D into half a right angle. This had a valve at D, opening from the receiver into the syringe, and shutting when pressed in the opposite direction. In the upper side of the syringe there is another valve F, opening from the syringe into the external air, and shutting when pressed inwards. The piston had no valve. The syringe, the cock B, and the joint of the tube, were immersed in a cistern filled with water. From this description, it is easy to understand the operation of the instrument. When the piston was drawn up from the bottom of the syringe, the valve F was kept shut by the pressure of the external air, and the valve D opened by the elasticity of the air in the receiver. When it was pushed down again, the valve D immediately shut by the superior elasticity of the air in the syringe; and when this was sufficiently compressed, it opened the valve F, and was discharged. It was immersed in water, that no air might find its way through the joints or cocks.

Its imperfections.

It would seem that this machine was not very perfect; for Guericke says, that it took several hours to produce an evacuation of a moderate-sized vessel; but he says, that when it was in good order, the rarefaction was so great, that

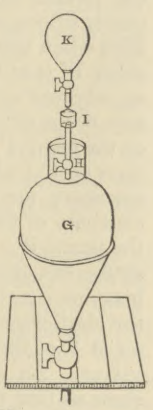
Air-pump.

when the cock was opened, and water admitted, it filled the receiver so as sometimes to leave no more than the bulk of a pea filled with air. This is a little surprising; for if the valve F be placed as far from the bottom of the syringe as in Schottus' figure,[1] it would appear that the rarefaction could not be greater than what must arise from the air in DF, expanding till it filled the whole syringe: because, as soon as the piston in its descent passes F, it can discharge no more air, but must compress it between F and the bottom, to be expanded again when the piston is drawn up. It is probable that the piston was not very tight, but that on pressing it down, it allowed the air to pass it; and the water in which the whole was immersed prevented the return of the air when it was drawn up again; and this accounts for the great time necessary for producing the desired rarefaction.

His improvement of it.

Guericke added a part to the machine, which saved his numerous visitants the trouble of hours' attendance, before they could see the curious experiments with rarefied air. He made a large copper vessel G (fig. 17.), having a pipe and cock below, which passed through the floor of the chamber into an under apartment, where it was joined to the syringe immersed in the cistern of water, and worked by a lever. The upper part of the vessel terminated in a pipe, furnished with a stopcock H, surrounded with a small brim to hold water for preventing the ingress of air. On the top was another cap I, also filled with water, to protect the junction of the pipes with the receiver K. This great vessel was always kept exhausted, and workmen attended below. When experiments were to be performed in the receiver K, it was set on the top of the great vessel, and the cock H was opened. The air in K immediately diffused itself equally between the two vessels, and was so much more rarefied as the receiver K was smaller than the vessel G. When this rarefaction was not sufficient, the attendants below immediately worked the pump.

Fig. 17.



Guericke's method of excluding air from all the joints of his apparatus, by immersing these joints in water, is the only method that has to this day been found effectual; and there frequently occur experiments where this exclusion for a long time is absolutely necessary. In such cases it is necessary to construct little cups or cisterns at every joint, and to fill them with water or oil. In a letter to Schottus, 1662–3, he describes very ingenious contrivances for producing complete rarefaction after the elasticity of the remaining air has been so far diminished that it is not able to open the valves. He opens the exhausting valves by a plug, which is pushed in by the hand; and the discharging valve is opened by a small pump placed on its outside, so that it opens into a void instead of opening against the pressure of the atmosphere.[2] These contrivances have been lately added to air-pumps by Haas and Hurter as new inventions.

Merits of Guericke.

It must be acknowledged, that the application of the pump or syringe to the exhaustion of air was a very obvious thought on the principle exhibited in fig. 3; and in this way it was also employed by Guericke, who first filled the receiver with water, and then applied the syringe. But this was by no means either his object or his principle. His object was not solely to procure a vessel void of air, but to exhaust the air which was already in it; and his principle was the power which he suspected to be in air of expanding itself into a greater space when the force was removed which he supposed to compress it. He expressly says,[3] that the contrivance occurred to him accidentally when occupied with experiments in the Toricellian tube, in which he found that the air would really expand, and completely fill a much larger space than what it usually occupied, and that he had found no limits to the expansion, evincing this by facts which we shall perfectly understand by and bye. This was a doctrine quite new, and required a philosophical mind to view it in a general and systematic manner; and it must be owned, that his manner of treating the subject is equally remarkable for ingenuity and for modesty.

Air-pump.

Progress of experimental philosophy.

His doctrine and his machine were soon spread over Europe. It was the age of literary ardour and philosophical curiosity; and it is most pleasant to us, who, standing on the shoulders of our predecessors, can see far around us, to observe the eagerness with which every new, and to us frivolous, experiment was repeated and canvassed.

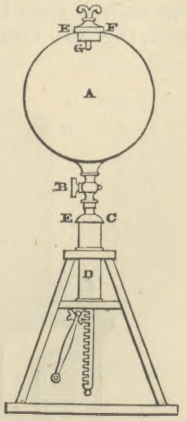
Ardour of Mr. Boyle.

About this time the foundations of the Royal Society of London were laid. Mr. Boyle, Mr. Wren, Lord Brounker, Dr. Wallis, and others, held meetings at Oxford, in which were received accounts of whatever was doing in the study of nature; and many experiments were exhibited. The researches of Galileo, Toricelli, and Pascal, concerning the pressure of the air, greatly engaged their attention, and many additions were made to their discoveries. Mr. Boyle, the most ardent and successful studier of nature, had the principal share in these improvements, his inquisitive mind being aided by an opulent fortune. In a letter to his nephew Lord Dungarvon, he says that he had made many attempts to see the appearances exhibited by bodies freed from the pressure of the air. He had made Toricellian tubes, having a small vessel a-top, into which he put some bodies before filling the tubes with mercury; so that when the tube was set upright, and the mercury run out, the bodies were *in vacuo*. He had also abstracted the water from a vessel by a small pump, by means of its weight, in the manner shewn in fig. 3, having previously put bodies into the vessel along with the water. But all these ways were very troublesome and imperfect. He was delighted when he learned from Schottus' first publication, that Guericke had effected this by the expansive power of the air; and immediately set about constructing a machine from his own ideas, no description of Guericke's being then published.

His air-pump.

It consisted of a receiver A, (fig. 18.) furnished with a stopcock B, and syringe CD placed in a vertical position below the receiver. Its valve C was in its bottom, close adjoining to the entry of the pipe of communication; and the hole by which the air issued was farther secured by a plug which could be removed. The piston was moved by a wheel and rack-work. The receiver of Guericke's pump was but ill adapted for any considerable variety of experiments; and accordingly very few were made in it. Mr. Boyle's receiver had a large opening EF, with a strong glass margin. To this was fitted a strong brass cap, pierced with a hole G in its middle, to which was fitted a

Fig. 18.



---

[1] In Guericke's own account of these discoveries, published in 1672, eight years after the *Technica Curiosa*, the valve is represented at *f*, close to the bottom of the syringe; hence it would appear that the representing it in the middle at F was a blunder of Schottus.—Ed.

[2] See Schotti *Technica Curiosa*, p. 68—70.

[3] *Tractatus de Experimentis Magdeburgicis, et Epistolæ ad Schottum.*

plug ground into it, and shaped like the key of a cock. The extremity of this key was furnished with a screw, to which could be affixed a hook, or a variety of pieces for supporting what was to be examined in the receiver, or for producing various motions within it, without admitting the air. This was farther guarded against by means of oil poured round the key, where it was retained by the hollow cup-like form of the cover. With all these precautions, however, Mr. Boyle ingenuously confesses, that it was but seldom, and with great difficulty, that he could produce an extreme degree of rarefaction; and it appears by Guericke's letter to Schottus that in this respect the Magdeburgh machine had the advantage. But most of Boyle's very interesting experiments did not require this extreme rarefaction; and the variety of them, and their philosophic importance, compensated for this defect, and soon eclipsed the fame of the inventor to such a degree, that the state of air in the receiver was generally denominated the *vacuum Boyleanum*, and the air-pump was called *machina Boyleana*.

His contrivances to make air-vessels tight.

Mr. Boyle found, that to make a vessel air-tight, it was sufficient to place a piece of wet or oiled leather on its brim, and to lay a flat plate of metal on this. The pressure of the external air squeezed the two solid bodies so hard together, that the soft leather effectually excluded it. This enabled him to render the whole machine incomparably more convenient for a variety of experiments. He caused the conduit-pipe to terminate in a flat plate which he covered with leather, and on this he set the glass ball or receiver, which had both its upper and lower brim ground flat. He covered the upper orifice in like manner with a piece of oiled leather and a flat plate, having cocks and a variety of other perforations and contrivances suited to his purposes. This he found infinitely more expeditious, and also tighter than the clammy cements which he had formerly used for securing the joints.

Dr Hooke's improvement of Boyle's air-pump.

He was now assisted by Dr. Hooke, the most ingenious and inventive mechanic that the world has ever seen. This person made a great improvement on the air-pump, by applying two syringes AA, (fig. 19), whose pistons P and P′ are both worked by one wheel, O pitching in the racks or piston rods R and R′, the pistons being thus raised and depressed alternately by turning the winch W backwards and forwards. In the bottom of each of the barrels there is an opening communicating with the receiver or bell glass B, placed on the plate A, (fig. 20). Over these openings valves of oiled silk are so placed as to admit of the passage of the air from the receiver to the syringe or barrel, but to oppose its passage from the barrel to the receiver. Now, suppose either of the pistons to be at the bottom of its barrel, it is obvious, that on drawing it up a vacuum will be found in the lower portion of the barrel, until the air in the receiver, by its elastic force, opening the valve V or V′, rushes in, distributing itself equally betwixt the barrel and receiver, but as the pistons are furnished with valves P and P′ similar to and opening in the same direction as VV′; on the descent of the piston the air which occupies the space betwixt the piston and bottom of the barrel being prevented from returning to the receiver by the valve V or V′, opens the valve in the piston and escapes into the apartment, with the air of which the piston valve communicates. This evidently doubled the expedition of the pump's operation; but it also greatly diminished the labour of pumping; for it must be observed, that the piston P must be drawn up against the pressure of the external air, and when the rarefaction is nearly perfect, this requires a force of nearly fifteen pounds for every inch of the area of the piston. Now when one piston P is at the bottom of the barrel, the other P′ is at the top of the barrel, and the air below P′ is equally rare with that in the receiver. Therefore the pressure of the external air on the piston P′ is *nearly* equal to that on the piston P. Both, therefore, are acting in opposite directions on the wheel which gave them motion; and the force necessary for raising P is only the difference between the elasticity of the air in the barrel P, and that of the air in the barrel P′. This is very small in the beginning of the stroke, but gradually increases as the piston P′ descends, and becomes equal to the whole excess of the air's pressure above the elasticity of the remaining air of the receiver, when the air at P of the natural density begins to open the piston valves. An accurate attention to the circumstances will show us that the force requisite for working the pump is greatest at first, and gradually diminishes as the rarefaction advances; and when this is nearly complete, hardly any more force is required than what is necessary for overcoming the friction of the pistons, except during the discharge of the air at the end of each stroke. This is therefore the form of the air-pump which is most generally used over all Europe; though in the various modifications some traces of national prepossession remain. We shall give a description of Boyle's air-pump as finally improved by Hawkesbee, which, with some small accommodations to particular views, continued for many years the most approved form.

Fig. 19.

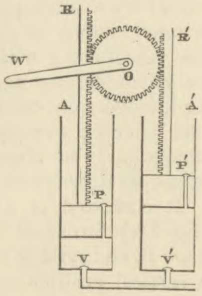


Fig. 20.

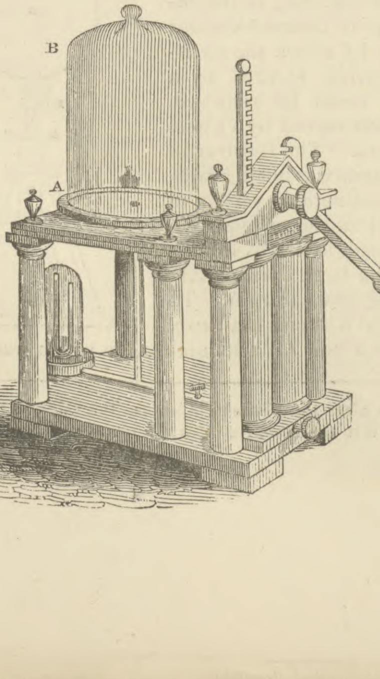
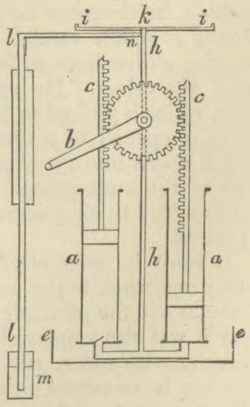


Hawkesbee's improvements

It consists of two brass barrels *a a*, (fig. 21.) twelve inches high, and two wide. The pistons are raised and depressed by turning the winch *b*. This is fastened to an axis passing through a strong toothed wheel, which lays hold of the teeth of the racks *c c*. Then the one is raised while the other is depressed; by which means the valves, which are made of limber bladder, fixed in the upper part of each piston, as well as in the openings into the bottom of the barrels, perform their office of discharging the air from the barrels, and admitting into them the air from the receiver to be afterwards discharged; and when the receiver comes to be pretty well exhausted of its air, the pressure of the atmosphere in the descending piston is nearly so great, that the power required to raise the other is little more than is necessary for overcoming the friction of the piston, which renders this pump preferable to all

Fig. 21.



others, which require more force to work them as the rarefaction of the air in the receiver advances.

The barrels are set in a brass dish *ee*, about two inches deep, filled with water or oil to prevent the insinuation of air. The barrels are screwed tight down by two nuts, which force the frontispiece down on them, through which the two pillars pass; for the sake of distinctness, these are omitted in this figure, but are shown in fig. 20.

From between the barrels rises a slender brass pipe *h h*, communicating with each by a perforation in the transverse piece of brass on which they stand. The upper end of this pipe communicates with another perforated piece of brass, which screws on underneath the plate *i i*, of ten inches diameter, and surrounded with a brass rim to prevent the shedding of water used in some experiments. This piece of brass has three branches. 1st, An horizontal one communicating with the conduit pipe *h h*. 2d, An upright one, screwed into the middle of the pump plate, and terminating in a small pipe, rising about an inch above it. 3d, A perpendicular one, looking downwards in the continuation of this pipe, and having a hollow screw in its end receiving the brass cap of the gage-pipe *l l*, which is of glass, thirty-four inches long, and immersed in a glass cistern *m* filled with mercury. This is covered a-top with a cork float, carrying the weight of a light wooden scale divided into inches, which are numbered from the surface of the mercury in the cistern. This scale will therefore rise and fall with the mercury in the cistern, and indicate the true elevation of that in the tube.

There is a stop-cock immediately above the insertion of the gage-pipe, by which its communication may be cut off. There is another at *n*, by which a communication is opened with the external air, for allowing its readmission; and there is sometimes another immediately within the insertion of the conduit-pipe for cutting off the communication between the receiver and the pump. This is particularly useful when the rarefaction is to be continued long, as there are by these means fewer chances of the insinuation of air by the many joints.

The receivers are made tight by simply setting them on the pump-plate, with a piece of wet or oiled leather between; and the receivers, which are open a-top, have a brass cover set on them in the same manner. In these covers there are various perforations and contrivances for various purposes. The one in fig. 26 has a slip wire passing through a collar of oiled leather, having a hook or a screw in its lower end, for hanging any thing on, or producing a variety of motions.

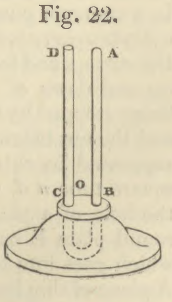
Sometimes the receivers are set on another plate, which has a pipe screwed into its middle, furnished with a stop-cock and a screw, which fits the middle pipe *k*. When the rarefaction has been made in it, the cock is shut, and then the whole may be unscrewed from the pump, and removed to any convenient place. This is called a *transporter plate.*

It only remains to explain the gage *ll*. In the ordinary state of the air, its elasticity balances the pressure of the incumbent atmosphere. We find this from the force that is necessary to squeeze it into less bulk in opposition to this elasticity. Therefore the elasticity of the air increases with the vicinity of its particles. It is therefore reasonable to expect, that when we allow it to occupy more room, and its particles are further asunder, its elasticity will be diminished though not annihilated; that is, it will no longer balance the WHOLE pressure of the atmosphere, though it may still balance part of it. If therefore an upright pipe have its lower end immersed in a vessel of mercury, and communicate by its upper end with a vessel containing rarefied, therefore less elastic air, we should expect that the pressure of the air will prevail, and force the mercury into the tube, and cause it to rise to such a height that the weight of the mercury, joined to the elasticity of the rarefied air acting on its upper surface, shall be exactly equal to the whole pressure of the atmosphere. The height of the mercury is the exact measure of that part of the whole pressure which is not balanced by the elasticity of the rarefied air, and its deficiency from the height of the mercury in the Toricellian tube is the exact measure of this remaining elasticity.

It is evident, therefore, that the pipe will be a scale of the elasticity of the remaining air, and will indicate in some sort the degree of rarefaction; for there must be some relation between the density of the air and its elasticity; and we have no reason to imagine that they do not increase and diminish together, although we may be ignorant of the law, that is, of the change of elasticity corresponding to a known change of density. This is to be discovered by experiment; and the air-pump itself furnishes us with the best experiments for this purpose. After rarefying till the mercury in the gage has attained half the height of that in the Toricellian tube, shut the communication with the barrels and gage, and admit the water into the receiver. It will go in till all is again in equilibrio with the pressure of the atmosphere; that is, till the air in the receiver has collapsed into its natural bulk. This we can accurately measure, and compare with the whole capacity of the receiver; and thus obtain the precise degree of rarefaction corresponding to half the natural elasticity. We can do the same thing with the elasticity reduced to one-third, one-fourth, &c. and thus discover the whole law.

This gage must be considered as one of the most ingenious and convenient parts of Hawkesbee's pump; and it is well disposed, being in a situation protected against accidents; but it necessarily increases greatly the size of the machine, and cannot be applied to the table-pump represented in fig. 20. When it is wanted here, a small plate is added behind, or between the barrels and receiver; and on this is set a small tubulated (as it is termed) receiver, covering a common weather-glass tube. This receiver being rarefied along with the other, the pressure on the mercury in the cistern arising from the elasticity of the remaining air, is diminished so as to be no longer able to support the mercury at its full height; and it therefore descends till the height at which it stands puts it in equilibrio with the elasticity. In this form, therefore, the height of the mercury is directly a measure of the remaining elasticity; while in the other it measures the remaining unbalanced pressure of the atmosphere. But this gage is extremely cumbersome, and liable to accidents. We are seldom much interested in the rarefaction till it is great; a contracted form of this gage is therefore very useful, and was early used. A syphon ABCD (fig. 22.) each branch of which is about four inches long, close at A and open at D, is filled with boiling mercury till it occupies the branch AB, and a very small part of CD, having its surface at O. This is fixed to a small stand, and fixed into the receiver, along with the things that are to be exhibited in the rarefied air. When the air has been rarefied till its remaining elasticity is not able to support the column BA, the mercury descends in AB, and rises in CD, and the remaining elasticity will always be measured by the elevation of the mercury in AB above that in the leg CD. Could the exhaustion be perfected, the surfaces in both legs would be on a level. Another gage might be put into the same foot, having a small bubble of air at A. This would expand from the beginning of the rarefaction; but our knowledge of the relation between the density and elasticity does not warrant us in using it as a measure of either.

Fig. 22.



A complete exhaustion not effected by the air-pump.

It is enough for our present purpose to observe, that the barometer gage is a perfect indication and measure of the performance of an air-pump, and that a pump is, *cæteris paribus*, so much the more perfect, as it is able to raise the mercury higher in the gage. It is in this way that we discover that none can produce a complete exhaustion, and that their operation is only a very great rarefaction: for none can raise the mercury to that height at which it stands in the Toricellian tube, well purged of air. Few pumps will bring it within one-tenth of an inch. Hawkesbee's, fitted up according to his instructions, will seldom bring it within one-fifth. Pumps with cocks, when constructed according to the principles mentioned when speaking of the exhausting syringe, and new and in fine order, will in favourable circumstances bring it within one-fortieth. None with valves fitted up with wet leather, or when water or volatile fluids are allowed access into any part, will bring it nearer than one-fifth. Nay, a pump of the best kind, and in the finest order, will have its rarefying power reduced to the lowest standard, as measured by this gage, if we put into the receiver the tenth part of a square inch of white sheep-skin, fresh from the shops, or of any substance equally damp. This is a discovery made by means of the improved air-pump, and leads to very extensive and important consequences in general physics, some of which will be treated of under this article; and the observation is made thus early, that our readers may better understand the improvements which have been made on this celebrated machine.

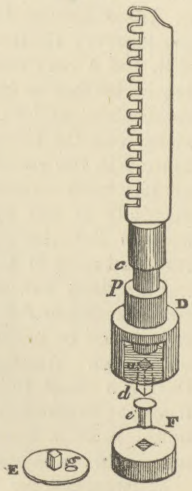
Various improvements of this machine.

It would require a volume to describe all the changes which have been made on it. An instrument of such multifarious use, and in the hands of curious men, each diving into the secrets of nature in his favourite line, must have received many alterations and real improvements in many particular respects. But these are beside our present purpose; which is to consider it merely as a machine for rarefying elastic or expansive fluids. We must therefore confine ourselves to this view of it; and shall carefully state to our readers every improvement founded on principle, and on pneumatical laws. All who used it perceived the limit set to the rarefaction by the resistance of the valves, and tried to perfect the construction of the cocks. The Abbé Nollet and s'Gravesande, two of the most eminent experimental philosophers in Europe, were the most successful.

s'Gravesande's improvement.

Mr. s'Gravesande justly preferred Hooke's plan of a double pump, and contrived an apparatus for turning the cocks by the motion of the pump's handle. This is far from either being simple or easy in working; and occasions great jerks and concussions in the whole machine. This, however, is not necessarily connected with the truly pneumatical improvement. His piston has no valve, and the rod is connected with it by a stirrup D (fig. 23), as in a common pump. The rod has a cylindric part *c p*, which passes through the stirrup, and has a stiff motion in it up and down of about half an inch; being stopped by the shoulder *c* above and the nut below. The round plate supported by this stirrup has a short square tube *n d*, which fits tight into the hole of a piece of cork F. The round plate E has a square shank *g*, which goes into the square tube *n d* A piece of thin leather, soaked in oil, is put between the cork and the plate E, and another between the cork and the plate which forms the sole of the stirrup. All these pieces are screwed together to form the piston by the nail *e*, whose flat head covers the hole *n*. Suppose, therefore, the piston touching the bottom of the barrel, and the winch turning to raise it again, the friction of the piston on the barrel keeps it in its place, and the rod is drawn up through the stirrup D. Thus the wheel has liberty to turn about an inch; and this is sufficient for turning the cock, so as to cut off the communication with the external air, and to open the communication with the receiver. This being done, and the motion of the winch continued, the piston is raised to the top of the barrel. When the winch is turned in the opposite direction, the piston remains fixed till the cock is turned, so as to shut the communication with the receiver, and open that with the external air.

Fig. 23.



This is a pretty contrivance, and does not at first appear necessary; because the cocks might be made to turn at the beginning and end of the stroke without it. But this is just possible; and the smallest error of adjustment, or wearing of the apparatus, will cause them to be open at improper times. Besides, the cocks are not turned in an instant, and are improperly open during some very small time; but this contrivance completely obviates the difficulty.

The cock is precisely similar to that formerly described, having one perforation diametrically through it, and another entering at right angles to this, and after reaching the centre, it passes along the axis of the cock, and comes out to the open air.

Its inconveniences remedied.

It is evident, that by this construction of the cock, the ingenious improvement of Dr. Hooke, by which the pressure of the atmosphere on one piston is made to balance, in great part, the pressure on the other, is given up: for, whenever the communication with the air is opened, it rushes in, and immediately balances the pressure on the upper side of the piston in this barrel; so that the whole pressure in the other must be overcome by the person working the pump. Gravesande, aware of this, put a valve on the orifice of the cock; that is, tied a slip of wet bladder or oiled leather across it; and now the piston is pressed down, as long as the air in the barrel is rarer than the outward air, in the same manner as when the valve is in the piston itself.

This is all that is necessary to be described in Mr. s'Gravesande's air pump. Its performance is highly extolled by him, as far exceeding his former pumps with valves. The same preference was given to it by his successor Muschenbrock. But, while they both prepared the pistons and valves and leathers of the pump, by steeping them in oil, and then in a mixture of water and spirits of wine, we are certain that no just estimate could be made of its performance. For with this preparation it could not bring the gage within one-fifth of an inch of the barometer. We even see other limits to its rarefaction: from its construction, it is plain that a very considerable space is left between the piston and cock, not less than an inch, from which the air is never expelled; and if this be made extremely small, it is plain that the pump must be worked very slow, otherwise there will not be time for the air to diffuse itself from the receiver into the barrel, especially towards the end, when the expelling force, viz. the elasticity of the remaining air, is very small. There is also the same limit to the rarefaction, as in Hooke's or Hawkesbee's pump, opposed by the valve, which will not open till the air below the piston is considerably denser than the external air; and this pump soon lost any advantages it possessed when fresh from the workman's hands, by the cock's growing loose and admitting air. It is surprising that Gravesande omitted Hawkesbee's security against this, by placing the barrels in a dish filled with oil; which would effectually have prevented this inconvenience.

Advantage of short barrels

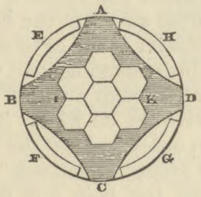
We must not omit a seemingly paradoxical observation of s'Gravesande, that in a pump constructed with valves, and worked with a determined uniform velocity, the required degree of rarefaction is sooner produced by short barrels than by long ones. It would require too much time to give a general demonstration of this, but it will easily be seen by an example. Suppose the long barrel to have equal capacity with the receiver, then at the end of the first stroke the air in the receiver will have one-half its natural density. Now, let the short barrels have half this capacity: at the end of the first stroke the density of the air in the receiver is two-thirds, and at the end of the second stroke it is four-ninths, which is less than one-half, and the two strokes of the short barrel are supposed to be made in the same time with one of longest, &c.

The valve pump improved by Smeaton.

Hawkesbee's pump maintained its pre-eminence without rival in Britain, till about the year 1750, when it engaged the attention of Mr. John Smeaton. He was then a maker of philosophical instruments, and made many attempts to perfect the pumps with cocks, but found, that whatever perfection he could bring them to, he could not enable them to preserve it; and he never would sell one of this construction. He therefore attached himself solely to the valve pumps.

The first thing was to diminish the resistance to the entry of the air from the receiver into the barrels; and this he rendered almost nothing, by enlarging the surface on which this feebly elastic air was to press. Instead of making these valves to open by its pressure on a circle of one-twentieth of an inch in diameter, he made the valve-hole one inch in diameter, enlarging the surface 400 times; and, to prevent this piece of thin leather from being burst by the great pressure on it, when the piston in its descent was approaching the bottom of the barrel, he supported it by a delicate but strong grating, dividing the valve-hole like the section of a honey-comb, as represented in fig. 24; and the ribs of this grating are seen edgewise in fig. 25, at *a b c*.

Fig. 24.



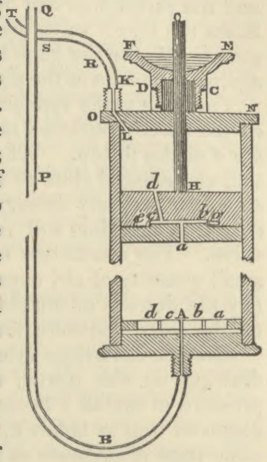
The valve was a piece of thin membrane or oiled silk, gently strained over the mouth of the valve-hole, and tied on by a fine silk thread wound round it in the same manner that the narrow slips had been tied on formerly. This done, he cut with a pointed knife the leather round the edge, nearly four quadrantal arcs, leaving a small tongue between each, as in fig. 24. The strained valve immediately shrinks inwards, as represented by the shaded parts; and the strain by which it is kept down is now greatly diminished, taking place only at the corners. The gratings being reduced nearly to an edge (but not quite, lest they should cut), there is very little pressure to produce adhesion by the clammy oil. Thus it appears, that a very small elasticity of the air in the receiver will be sufficient to raise the valve; and Mr. Smeaton found, that when it was not able to do this at first, when only about $\frac{1}{600}$ of the natural elasticity, it would do it after keeping the piston up eight or ten seconds, the air having been all the while undermining the valve, and gradually detaching it from the grating.

Unfortunately he could not follow this method with the piston valve. There was not room round the rod for such an expanded valve; and it would have obliged him to have a great space below the valve, from which he could not expel the air by the descent of the piston. His ingenuity hit on a way of increasing the expelling force through the common valve. He inclosed the rod of the piston in a collar of leather D C (fig. 25,) through which it moved freely without allowing any air to get past its sides. For greater security, the collar of leather was contained in a box terminating in a cup filled with oil. As this makes a material change in the principle of construction of the air-pump, and indeed of pneumatic engines in general, and as it has been adopted in all the subsequent attempts to improve them, it merits a particular consideration.

Structure of his piston.

The piston itself consists of two pieces of brass fastened by screws from below. The uppermost, which is of one solid piece with the rod GH (fig. 25), is of a diameter somewhat less than the barrel; so that when they are screwed together, a piece of leather soaked in a mixture of boiled oil and tallow, is put between them; and when the piston is thrust into the barrel from above, the leather comes up around the side of the piston, and fills the barrel, making the piston perfectly air-tight. The lower half of the piston projects upwards into the upper, which has a hollow *g b c e* to receive it. There is a small hole through the lower half at *a* to admit the air; and a hole *c d* in the upper half to let it through, and there is a slip of oiled silk strained across the hole *a* by way of valve, and there is room enough left at *b c* for this valve to rise a little when pressed from below. The rod GH passes through the piece of brass which forms the top of the barrel so as to move freely, but without any sensible shake: this top is formed into a hollow box, consisting of two pieces ECDF and CNOD, which screw together at CD. This box is filled with rings of oiled leather exactly fitted to its diameter, each having a hole in it for the rod to pass through. When the piece ECDF is screwed down, it compresses the leathers; squeezing them to the rod, so that no air can pass between them; and, to secure us against all ingress of air, the upper part is formed into a cup EF, which is kept filled with oil.

Fig. 25.



The top of the barrel is also pierced with a hole LK, which rises above the flat surface NO, and has a slip of oiled silk tied over it to act as a valve; opening when pressed from below, but shutting when pressed from above.

The communication between the barrel and receiver is made by means of the pipe ABPQ; and there goes from the hole K in the top of the barrel a pipe KRST, which either communicates with the open air or with the receiver, by means of the cock at its extremity T. The conduit pipe ABPQ has also a cock at Q, by which it is made to communicate either with the receiver or with the open air. These channels of communication are variously conducted and terminated, according to the views of the maker. The sketch in this figure is sufficient for explaining the principle, and is suited to the general form of the pump, as it has been frequently made by Nairne and other artists in London.

Superiority of this construction.

Let us now suppose the piston at the top of the barrel, that it applies to it all over, and that the air in the barrel is very much rarefied: In the common pump the piston valve is pressed hard down by the atmosphere, and continues shut till the piston gets far down, condenses the air below it beyond its natural state, and enables it to force up the valves. But here, as soon as the piston quits the top of the barrel, it leaves a void behind it; for no air gets in round the piston rod, and the valve at K is shut by the pressure of the atmosphere. There is nothing now to oppose the elasticity of the air below but the stiffness of the valve *b c*; and thus the expelling (or more accurately the liberating) force is prodigiously increased.

The superiority of this construction will be best seen by an example. Suppose the stiffness of the valve equal to the weight of 1-10th of an inch of mercury, when the barometer stands at 30 inches, and that the pump-gage stands at 29·9; then, in an ordinary pump, the valve in the piston will not rise till the piston has got within the 300th part of the bottom of the barrel, and it will leave the valve-hole filled with air of the ordinary density. But in this pump the valve will rise as soon as the piston quits the top of the barrel; and when it is quite down, the valve-hole *a* will contain only the 300th part of the air which it would have contained in a pump of the ordinary form. Suppose, farther, that the barrel is of equal capacity with the receiver, Air-pump.

and that both pumps are so badly constructed, that the space left below the piston is the 300th part of the barrel. In the common pump the piston valve will rise no more, and the rarefaction can be carried no farther, however delicate the barrel valve may be; but in this pump the next stroke will raise the gage to 29·95, and the piston valve will again rise as soon as the piston gets half way down the barrel.

The limit to the rarefaction by this pump depends chiefly on the space contained in the hole LK, and in the space *b c d* of the piston. When the piston is brought up to the top, and applied close to it, those spaces remain filled with air of the ordinary density, which will expand as the piston descends, and thus will retard the opening of the piston valve. The rarefaction will stop when the elasticity of this small quantity of air, expanded so as to fill the whole barrel (by the descent of the piston to the bottom), is just equal to the force requisite for opening the piston valve.

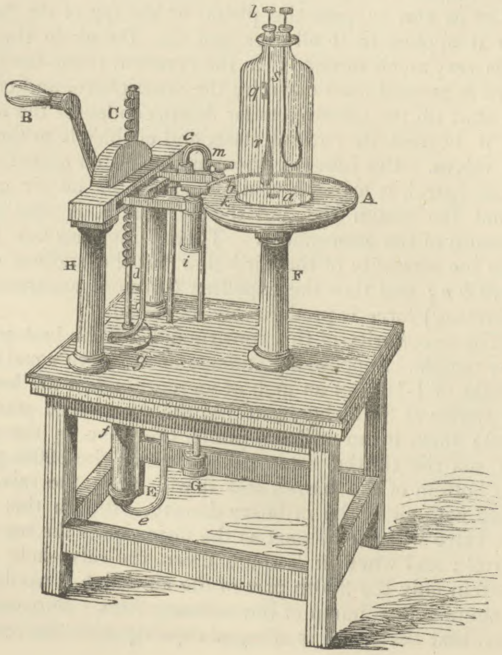
Another advantage attending this construction is, that in drawing up the piston, we are not resisted by the whole pressure of the air; because the air is rarefied above this piston as well as below it, and the piston is in precisely the same state of pressure as if connected with another piston in a double pump. The resistance to the ascent of the piston is the excess of the elasticity of the air above it over the elasticity of the air below; this, toward the end of the rarefaction, is very small, while the piston is near the bottom of the barrel, but gradually increases as the piston rises, and reduces the air above it into smaller dimensions, and becomes equal to the pressure of the atmosphere, when the air above the piston is of the common density. If we should raise the piston still farther, we must condense the air above it; but Mr. Smeaton has here made an issue for the air by a small hole in the top of the barrel, covered with a delicate valve. This allows the air to escape, and shuts again as soon as the piston begins to descend, leaving almost a perfect void behind it as before.

This pump has another advantage. It may be changed in a moment from a rarefying to a condensing engine, by simply turning the cocks at Q and T. Whilst T communicates with the open air and Q with the receiver, it is a rarefying engine or air-pump; but when T communicates with the receiver, and Q with the open air, it is a condensing engine.

Description of Smeaton's pump.

Fig. 26 represents Mr. Smeaton's air-pump as it was usually made by Nairne. Upon a solid base or table are set up three pillars F, H, H; the pillar F supports the pump-plate A, and the pillars H, H, support the front or head, containing a brass cog-wheel, which is turned by the handle B, and works in the rack C fastened to the upper end of the piston rod. The whole is still farther steadied by two pieces of brass *n* and *h*, which connect the pump-plate with the front, and have perforations communicating between the hole *a* in the middle of the plate and the barrel, as will be described immediately. DE is the barrel of the pump, firmly fixed to the table by screws through its upper flanch; *e f d c* is a slender brass tube screwed to the bottom of the barrel, and to the under side of the horizontal canal *n*. In this canal there is a cock *m*, which opens a communication between the barrel and the receiver, when the key is in the position represented here; but when the key is at right angles with this position, this communication is cut off. If that side of the key which is here drawn next to the pump-plate be turned outward, the external air is admitted into the receiver; but if turned inwards, the air is admitted into the barrel.

Fig. 26.



g h is another slender brass pipe, leading from the discharging valve at *g* to the horizontal canal *h k*, to the under side of which it is screwed fast. In this horizontal canal there is a cock *n* which opens a passage from the barrel to the receiver when the key is in the position here drawn; but opens a passage from the barrel to the external air when the key is turned outwards, and from the receiver to the external air when the key is turned inwards. This communication with the external air is not immediate but through a sort of box *i*; the use of this box is to receive the oil which is discharged through the top valve *g*. In order to keep the pump tight, and in working order, it is proper sometimes to pour a table-spoonful of olive oil into the hole *a* of the pump-plate, and then to work the pump. The oil goes along the conduit *b c d f e*, gets into the barrel and through the piston-valve, when the piston is pressed to the bottom of the barrel, and is then drawn up, and forced through the discharging valve *g* along the pipe *g h*, the horizontal passage *h n*, and finally into the box *i*. This box has a small hole in its side near the top, through which the air escapes.

From the upper side of the canal *n* there arises a slender pipe which bends outward and then turns downwards, and is joined to a small box, which cannot be seen in this view. From the bottom of this box proceeds downwards the gage-pipe of glass, which enters the cistern of mercury G fixed below.

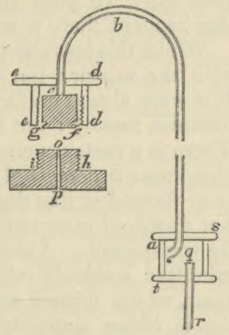
On the upper side of the other canal there is a small stud, having a short pipe of glass projecting horizontally from it, close by and parallel to the front piece of the pump, and reaching to the other canal. This pipe is close at the farther end, and has a small drop of mercury or oil in it. This serves as a gage in condensing, indicating the degree of condensation by the place of the drop; for this drop is forced along the pipe, condensing the air before it in the same degree that it is condensed in the barrel and receiver.

Method of joining together the different pipes, &c.

In constructing this pump, Mr. Smeaton introduced a method of joining together the different pipes and other pieces, which has great advantages over the usual manner of screwing them together with leather between, and which is now much used in hydraulic and pneumatic engines. We shall explain this to our readers by a description of the manner in which the exhausting gage is joined to the horizontal duct *c b*.

The piece *h i p*, in fig, 27, is the same with the little cylinder observable on the upper side of the horizontal canal *n*, in fig. 26. The upper part *h i* is formed into an outside screw, to fit the hollow screw of the piece *d e e d*. The top of this last piece has a hole in its middle, giving an easy passage to the bent tube *c b a*, so as to slip along it with freedom. To the end *c* of this bent tube is soldered a piece of brass *c f g*, perforated in continuation of the tube, and having its end ground flat on the top of the piece *h i p*, and also covered with a slip of thin leather strained across it and pierced with a hole in the middle.

Fig. 27.



It is plain from this form, that if the surface *f g* be applied to the top of *h i*, and the cover *d e e d* be screwed down on it, it will draw or press them together, so that no air can escape by the joint, and this without turning the whole tube *c b a* round, as is necessary in the usual way. This method is now adopted for joining together the conducting pipes of the machines for extinguishing fires, an operation which was extremely troublesome before this improvement.

The conduit pipe E *e f c* (fig. 26), is fastened to the bottom of the barrel, and the discharging pipe *g h* to its top, in the same manner. But to return to the gage; the bent pipe *c b a* (fig. 27), enters the box *s t* near one side, and obliquely, and the gage-pipe *q r* is inserted through its bottom towards the opposite side. The use of this box is to catch any drops of mercury which may sometimes be dashed up through the gage-pipe by an accidental oscillation. This, by going through the passages of the pump, would corrode them, and would act particularly on the joints, which are generally soldered with tin. When this happens to an air-pump, it must be cleaned with the most scrupulous attention, otherwise it will be quickly destroyed.

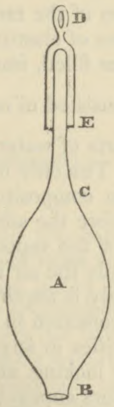
Great powers of this pump.

This account of Smeaton's pump is sufficient for enabling the reader to understand its operation and to see its superiority. It is reckoned a very fine pump of the ordinary construction which will rarefy 200 times, or raise the gage to 29·85, the barometer standing at 30. But Mr. Smeaton found, that his pump, even after long using, raised it to 29·95, which we consider as equivalent to rarefying 600 times. When in fine order, he found no bounds to its rarefaction, frequently raising the gage as high as the barometer; and he thought its performance so perfect,[1] that the barometer-gage was not sufficiently delicate for measuring the rarefaction. He therefore substituted the syphon-gage already described, which he gives some reasons for preferring; but even this he found not sufficiently sensible.

Another contrivance of Smeaton's.

He contrived another, which could be carried to any degree of sensibility. It consisted of a glass body A (fig. 28), of a pear shape, and was therefore called the pear-gage. This had a small projecting orifice at B, and at the other end a tube CD, whose capacity was the hundredth part of the capacity of the whole vessel. This was suspended at the slip-wire of the receiver, and there was set below it a small cup with mercury. When the pump was worked, the air in the pear-gage was rarefied along with the rest. When the rarefaction was brought to the degree intended, the gage was let down till B reached the bottom of the mercury. The external air being now let in, the mercury was raised into the pear, and stood at some height E in the tube CD. The length of this tube being divided into 100 parts, and those numbered from D, it is evident that $\frac{DE}{DB}$ will express the degree of rarefaction which had been produced when the gage was immersed into the mercury; or if DC be $\frac{1}{100}$ of the whole capacity, and be divided into 100 parts by a scale annexed to it, each unit of the scale will be $\frac{1}{10000}$ of the whole.

Fig. 28.



This was a very ingenious contrivance, and has been the means of making some very curious and important discoveries. By this gage Mr. Smeaton found, that his pump frequently rarefied a thousand, ten thousand, nay, an hundred thousand times. But though he in every instance saw the great superiority of his pump above all others, he frequently found irregularities which he could not explain, and a want of correspondence between the pear and the barometer gages which puzzled him. The pear-gage frequently indicated a prodigious rarefaction, when the barometer-gage would not show more than 600.

These unaccountable phenomena excited the curiosity of philosophers, who by this time were making continual use of the air-pump in their meteorological researches, and much interested in everything connected with the state or constitution of elastic fluids. Mr. Nairne, a most ingenious and accurate maker of philosophical instruments, made many curious experiments in the examination and comparison of Mr. Smeaton's pump with those of the usual construction, attending to every circumstance which could contribute to the inferiority of the common pumps or to their improvement, so as to bring them nearer to this rival machine. This rigorous comparison brought into view several circumstances in the constitution of the atmospheric air, and its relation to other bodies, which are of the most extensive and important influence in the operations of nature. We shall notice at present such only as have a relation to the operation of the air-pump in extracting AIR from the receiver.

Experiments with it by Mr. Nairne.

Mr. Nairne found, that when a little water, or even a bit of paper damped with water, was exposed under the receiver of Mr. Smeaton's air-pump, when in the most perfect condition, raising the mercury in the barometer-gage to 29·95, he could not make it rise above 29·8 if Fahrenheit's thermometer indicated the temperature 47°, nor above 29·7 if the thermometer stood at 55°; and that to bring the gage to this height and keep it there, the operation of the pump must be continued for a long time after the water had disappeared or the paper become perfectly dry. He found that a drop of spirits, or paper moistened with spirits, could not in those circumstances allow the mercury in the gage to rise to near that height; and that similar effects followed from admittting any volatile body whatever into the receiver or any part of the apparatus. This showed him at once how improper were the directions which had been given by Guericke, Boyle, Gravesande, and others, for fitting up the air-pump for experiment, by soaking the leather in water, covering the joints with water, or in short, admitting water or any volatile body near it.

He therefore took his pumps to pieces, cleared them of all the moisture which he could drive from them by heat, and then leathered them anew with leather soaked in a mixture of olive oil and tallow, from which he had expelled all the water it usually contains, by boiling it till the first frothing was over. When the pumps were fitted up in this manner, he uniformly found that Mr. Smeaton's pump rarefied the gage to 29·95, and the best common pump to 29·87, the first of which he computed to indicate a rarefaction to 600, and the other to 230. But in this state he again found that a piece of damp paper, leather, wood, &c. in the receiver, reduced the performance in the same manner as before.

Remarkable phenomenon.

But the most remarkable phenomenon was, that when he made use of the pear-gage with the pump cleared from all moisture, it indicated the same degree of rarefaction with the barometer-gage; but when he exposed a bit of paper moistened with spirits, and thus reduced the rarefaction of the pump to what he called 50, the barometer-gage standing at 29·4, the pear-gage indicated a rarefaction exceeding 100,000. In short, it was not measurable; and this phenomenon was almost constant. Whenever he exposed any substance susceptible of evaporation, he found the rarefaction indicated by the barometer-gage greatly reduced, whilst that indicated by the pear-gage was prodigiously increased; and both these effects were the more remarkable as the subject was of easier evaporation, or the temperament of the air of the chamber was warmer.

---

[1] This can only be explained by supposing that Mr. Smeaton employed an imperfect barometer.

This uniform result suggested the true cause. Water boils at the temperature of 212°, that is, it is then converted into a vapour which is permanently elastic while of that temperature, and its elasticity balances the pressure of the atmosphere. If this pressure be diminished by rarefying the air above it, a low temperature will now allow it to be converted into elastic vapour, and keep it in that state. Water will boil in the receiver of an air-pump at the temperature of 96°, or even under it. Philosophers did not think of examining the state of the vapour in temperatures lower than what produced ebullition. But it now appears, that in much lower heats than this the superficial water is converted into elastic vapour, which continues to exhale from it as long as the water lasts, and, supplying the place of air in the receiver, exerts the same elasticity, and hinders the mercury from rising in the gage in the same manner as so much air of equal elasticity would have done.

Experiments illustrative of this account.

When Mr. Nairne was exhibiting these experiments to the Hon. Henry Cavendish in 1770, this gentleman informed him that it appeared from a series of experiments of his father Lord Charles Cavendish, that when water is of the temperature 72°, it is converted into vapour, under any pressure less than three-fourths of an inch of mercury, and at 41° it becomes vapour when the pressure is less than one-fourth of an inch: even mercury evaporates in this manner when all pressure is removed. A dewy appearance is frequently observed covering the inside of the tube of a barometer, where we usually suppose a vacuum. This dew, when viewed through a microscope, appears to be a set of detached globules of mercury, and upon inclining the tube so that the mercury may ascend along it, these globules will be all licked up, and the tube become clear. The dew which lined it was the vapour of the mercury condensed by the side of the tube; and it is never observed but when one side is exposed to a stream of cold air from a window, &c.

To return to the vapour in the air-pump receiver; it must be observed, that as long as the water continues to yield it, we may continue to work the pump; and it will be continually abstracted by the barrels, and discharged in the form of water, because it collapses as soon as exposed to the external pressure. All this while the gage will not indicate any more rarefaction, because the thing immediately indicated by the barometer-gage is *diminished elasticity*, which does not happen here. When all the water which the temperature of the room can keep elastic has evaporated under a certain pressure, suppose half an inch of mercury, the gage standing at 29·5, the vapour which now fills the receiver expands, and by its diminished elasticity the gage rises, and now some more water which had been attached to bodies by chemical or corpuscular attraction is detached, and a new supply continues to support the gage at a greater height; and this goes on continually till *almost* all has been abstracted. But there will remain some which no art can take away; for as it passes through the barrels, and gets between the piston and the top, it successively collapses into water during the ascent of the piston, and again expands into vapour when we push the piston down again. Whenever this happens there is an end of the rarefaction.

Air and vapour not uniformly mixed together.

Whilst this operation is going on, the air comes out along with the vapour; but we cannot say in what proportion. If it were always uniformly mixed with the vapour, it would diminish rapidly; but this does not appear to be the case. There is a certain period of rarefaction in which a transient cloudiness is perceived in the receiver. This is watery vapour formed at that degree of rarefaction, mingled with, but not dissolved in or united with, the air, otherwise it would be transparent. A similar cloud will appear if damp air be admitted suddenly into an exhausted receiver. The vapour, which formed an uniform transparent mass with the air, is either suddenly expanded and thus detached from the other ingredient, or is suddenly let go by the air, which expands more than it does. We cannot affirm with probability which of these is the case. Different compositions of air, that is, air loaded with vapours from different substances, exhibit remarkable differences in this respect. But we see from this and other phenomena, which shall be mentioned in their proper places, that the air and vapour are not always intimately united; and therefore will not always be drawn out together by the air-pump. But let them be ever so confusedly blended, we see that the air must come out along with the vapour, and its quantity remaining in the receiver must be prodigiously diminished by this association, probably much more than could be, had the receiver only contained pure air.

Consequences of this.

Let us now consider what must happen in the pear-gage. As the air and vapour are continually drawn off from the receiver, the air in the pear expands and goes off with it. We shall suppose that the generated vapour hinders the gage from rising beyond 29·5. During the continued working of the pump, the air in the pear, whose elasticity is 0·5, slowly mixes with the vapour at the mouth of the pear, and the mixture even advances into its inside, so that if the pumping be long enough continued, what is in the pear is nearly of the same composition with what is in the receiver, consisting perhaps of 20 parts of vapour and one part of air, all of the elasticity of 0·5. When the pear is plunged into the mercury, and the external air allowed to get into the receiver, the mercury rises in the pear-gage, and leaves not $\frac{1}{60}$, but $\frac{1}{60\times 20}$ or $\frac{1}{1200}$ of it filled with common air, the vapour having collapsed into an invisible atom of water. Thus the pear-gage will indicate a rarefaction of 1200, while the barometer-gage only showed 60, that is, showed the elasticity of the included substance diminished 60 times. The conclusion to be drawn from these two measures (the one of the rarefaction of air, and the other of the diminution of elasticity) is, that the matter with which the receiver was filled, immediately before the readmission of the air, consisted of one part of incondensible air, and $\frac{1200}{60}$, or 20 parts of watery vapour.

Difficulty in accounting for some of these.

The only obscure part of this account is what relates to the composition of the matter which filled the pear-gage before the admission of the mercury. It is not easy to see how the vapour of the receiver comes in by a narrow mouth while the air is coming out by the same passage. Accordingly it requires a very long time to produce this extreme rarefaction in the pear-gage; and there are great irregularities in any two succeeding experiments, as may be seen by looking at Mr. Nairne's account of them.[1] Some vapours appear to have mixed much more readily with the air than others; and there are some unaccountable cases where vitriolic acid and sulphureous bodies were included, in which the dimunition of density indicated by the pear-gage was uniformly less than the diminution of elasticity indicated by the barometer-gage. It is enough for us at present to have established, by unquestionable facts, this production of elastic vapour, and the necessity of attending to it, both in the construction of the air-pump, and in drawing results from experiments exhibited in it.

---

[1] *Phil. Trans.* vol. lxvii.

Two new improvements.

Mr. Smeaton's pump, when in good order, and perfectly free from all moisture, will in dry weather rarefy air about 600 times, raising the barometer-gage to within $\frac{1}{20}$th of an inch of a fine barometer. This was a performance so much superior to that of all others, and by means of Mr. Nairne's experiments opened so new a field of observation, that the air-pumps once more became a capital instrument among the experimental philosophers. The causes of its superiority were also so distinct, that artists were immediately excited to a farther improvement of the machine; so that this becomes a new epoch in its history.

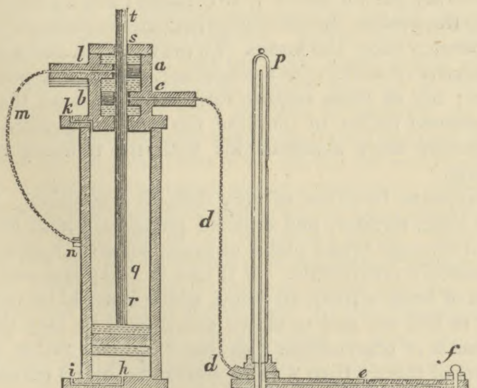
Improvements in this pump attempted.

There is one imperfection which Mr. Smeaton has not attempted to remove. The discharging valve is still opened against the pressure of the atmosphere. An author of the Swedish academy adds a subsidiary pump to this valve, which exhausts the air from above it, and thus puts it in the situation of the piston valve. We do not find that this improvement has been adopted so as to become general. Indeed the quantity of air which remains in the passage to this valve is so exceedingly little, that it does not seem to merit attention. Supposing the valve hole $\frac{1}{20}$th of an inch wide and as deep (and it need not be more), it will not occupy more than $\frac{1}{9000}$th part of a barrel twelve inches long and two inches wide.

Mr. Smeaton, by his ingenious construction, has greatly diminished, but has not annihilated, the obstructions to the passage of the air from the receiver into the barrel. His success encouraged farther attempts. One of the first and most ingenious was that of Professor Russell of the University of Edinburgh, who, about the year 1770, constructed a pump in which both cocks and valves were avoided.

The piston is solid, as represented in fig. 28, and its rod passes through a collar of leather on the top of the barrel. This collar is divided into three portions by two brass rings *a*, *b*, which leave a very small space round the piston rod. The upper ring *a* communicates by means of a lateral perforation with the bent tube, *l m n*, which enters the barrel at its middle *n*. The lower ring *b* communicates with the bent tube *c d*, which communicates with the horizontal passage *d e* going to the middle *e* of the pump plate. By the way, however, it communicates also with a barometer gage *p o*, standing in a cistern of mercury *o*, and covered with a glass tube close at the top. Beyond *e*, on the opposite circumference of the receiver plate, there is a cock or plug *f* communicating with the atmosphere.

Fig. 28.



The piston rod is closely embraced by the three collars of leather; but, as already said, has a free space round it in the two brass rings. To produce this pressure of the leathers to the rod, the brass rings which separate them are turned thinner on the inner side, so that their cross section along a diameter would be a taper wedge. In the side of the piston rod are two cavities *q r*, *t s*, about one-tenth of an inch wide and deep, and of a length equal to the thickness of the two rings *a b*, and the intermediate collar of leathers. These cavities are so placed on the piston-rod, that when the piston is applied to the bottom of the barrel, the cavity *t s* in the upper end of the rod has its upper end opposite to the ring *a*, and its lower end opposite to the ring *b*, or to the mouth of the pipe *c d*. Therefore, if there be a void in the barrel, the air from the receiver will come from the pipe *c d*, into the cavity in the piston-rod, and by it will get past the collar of leather between the rings, and thus will get into the small interstice between the rod and the upper ring, and then into the pipe *l m n*, and into the empty barrel. When the piston is drawn up, the solid rod immediately shuts up this passage, and the piston drives the air through the discharging valve *k*. When it has reached the top of the barrel, and is closely applied to it, the cavity *q r* is in the situation in which *t s* formerly was, and the communication is again opened between the receiver and the empty barrel, and the air is again diffused between them. Pushing down the piston expels the air by the lower discharging pipe and valve *h i*; and thus the operation may be continued.

This must be acknowledged to be a most simple and ingenious construction, and can neither be called a cock nor a valve. It seems to oppose no obstruction whatever; and it has the superior advantage of rarefying both during the ascent and the descent of the piston, doubling the expedition of the performance, and the operator is not opposed by the pressure of the atmosphere except towards the end of each stroke. The expedition, however, is not so great as one should expect; for nothing is going on while the piston is in motion, and the operator must stop a while at the end of each stroke, that the air may have time to come through this long, narrow, and crooked passage, to fill the barrel. But the chief difficulty which occurred in the execution arose from the clammy oil with which it was necessary to impregnate the collar of leathers. These were always in a state of strong compression, that they might closely grasp the piston rod, and prevent all passage of air during the motion of the piston. Whenever therefore the cavities in the piston rod come into the situations necessary for connecting the receiver and barrel, this oil is squeezed into them, and choaks them up. Hence it always happened that it was some time after the stroke before the air could force its way round the piston rod, carrying with it the clammy oil which choaked up the tube *l m n*; and when the rarefaction had proceeded a certain length, the diminished elasticity of the air was not able to make its way through these obstructions.

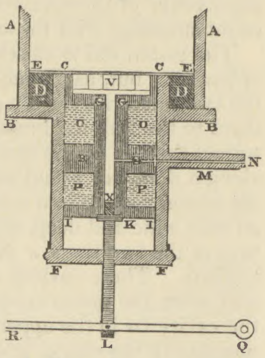
Mr. Cavallo[1] has given the description of an air-pump contrived and executed by Messrs Hans and Hurter, instrument makers in London, where these artists revived Guericke's method of opening the barrel-valve during the last strokes of the pump by a force acting from without. We shall insert as much of this description as relates to the distinguishing circumstance of its construction.

---

[1] *Phil. Trans.* vol. lxxiii.

Air-pump. Fig. 29 represents a section of the bottom of the barrel, where AA is the barrel, and BB the bottom, which has in its middle a hollow cylinder CCFF, projecting about half an inch into the barrel at CC, and extending a good way downwards to FF. The space between this projection and the sides of the barrel is filled up by a brass ring DD, over the top of which is strained a piece of oiled silk EE, which performs the office of a valve, covering the hole CC. But this hole is filled up by a piece of brass, or rather an assemblage of pieces screwed together GG, HH, II. It consists of three projecting fillets or shoulders GG, HH, II, which form two hollows between them, and which are filled with rings of oiled leather OO, PP, firmly screwed together. The extreme fillets GG, II, are of equal diameter with the inside of the cylinder, so as to fill it exactly, and the whole stuffed with oiled leather, slide up and down without allowing any air to pass. The middle fillet HH is not so broad, but thicker. In the upper fillet GG there is formed a shallow dish about $\frac{1}{8}$ of an inch deep and $\frac{3}{4}$ wide. This dish is covered with a thin plate, pierced with a grating like Mr. Smeaton's valve plate. There is a perforation VX along the axis of this piece, which has a passage out at one side H, through the middle fillet. Opposite to this passage, and in the side of the cylinder CC,FF, is a hole M, communicating with the conduit pipe MN, which leads to the receiver. Into the lower end of the perforation is screwed the pin KL, whose tail L passes through the cap FF. The tail L is connected with a lever RQ, moveable round the joint Q. This lever is pushed upwards by a spring, and thus the whole piece which we have been describing is kept in contact with the slip of oiled silk or valve EE. This is the usual situation of things.

Fig. 29.

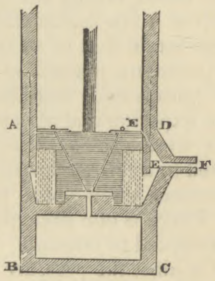


Now suppose a void formed in the barrel by drawing up the piston; the elasticity of the air in the receiver, in the pipe MN, and in the passage XV, will press on the great surface of the valve exposed through the grating, will raise it, and the pump will perform precisely as Mr. Smeaton's does. But suppose the rarefaction to have been so long continued, that the air is no longer able to raise the valve; this will be seen by the mercury rising no more in the pump-gage. When this is perceived, the operator must press with his foot on the end R of the lever RQ. This draws down the pin KL, and with it the whole hollow plug with its grated top. And thus, instead of raising the valve from its plate, the plate is here drawn down from the valve. The air now gets in without any obstruction whatever, and the rarefaction proceeds as long as the piston rises. When it is at the top of the barrel, the operator takes his foot from the lever, and the spring presses up the plug again and shuts the valve. The piston rod passes through a collar of leather, as in Mr. Smeaton's pump, and the air is finally discharged through an outward valve in the top of the barrel. These parts have nothing peculiar in them.

This is an ingenious contrivance, similar to what was adapted by Guericke himself; and we have no doubt of these pumps performing extremely well if carefully made; and it seems not difficult to keep the plug perfectly air-tight by supplying plenty of oil to the leathers. We cannot say, however, with precision, what may be expected from it, as no account has been given of its effects, besides what Mr. Cavallo published in the *Philosophical Transactions* for 1783, where he only says, that when it had been long used, it had, in the course of some experiments, rarefied 600 times.

Air-pump. Prince. Aiming still at the removing the obstructions to the entry of the air from the receiver into the barrels, Mr. Prince, an American, has constructed a pump in which there is no valve or cock whatever between them. In this pump the piston rod passes through a collar of leather, and the air is finally discharged through a valve, as in the two last. But we are chiefly to attend, in this place, to the communication between the barrel and the receiver. The barrel widens below into a sort of cistern ABCD, communicating with the receiver by the pipe EF. As soon, therefore, as the piston gets into this wider part, where there is a vacancy all round it, the air of the receiver expands freely through the passage FEE into the barrel, in which the descent of the piston had made a void. When the piston is again drawn up, as soon as it gets into the cylindric part of the barrel, which it exactly fills, it carries up the air before it, and expels it by the top valve; and, that this may be done more completely, this valve opens into a second barrel or air-pump whose piston is rising at the same time, and therefore the valve of communication (which is the discharging valve of the primary pump) opens with the same facility as Mr. Smeaton's piston valve. While the piston is rising, the air in the receiver expands into the barrel; and when the piston descends, the air in the barrel again collapses till the piston gets again into the cistern, when the air passes out, and fills the evacuated barrel, to be expelled by the piston as before.

Fig. 30.



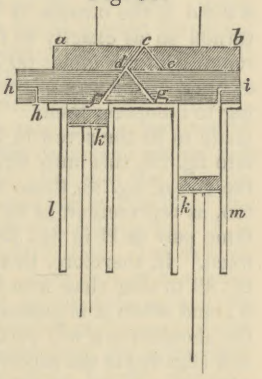
No distinct account has yet been given of the performance of this pump. We only learn that great inconveniences were experienced from the oscillations of the mercury in the gage. As soon as the piston comes into the cistern, the air from the receiver immediately rushes into the barrel, and the mercury shoots up in the gage, and gets into a state of oscillation. The subsequent rise of the piston will frequently keep time with the second oscillation, and increase it. The descent of the piston produces a downward oscillation, by allowing the air below it to collapse; and by improperly timing the strokes, this oscillation becomes so great as to make the mercury enter the pump. To prevent this, and a greater irregularity of working as a condenser, valves were put in the piston; but as these require force to open them, the addition seemed rather to increase the evil, by rendering the oscillations more simultaneous with the ordinary rate of working.

It appears, however, of very difficult execution. It has many long, slender, and crooked passages, which must be drilled through broad plates of brass, some of them appearing scarcely practicable. It is rare to find plates and other pieces of brass without air-holes, which it would be very difficult to find out and to close; and it must be very difficult to clear it of obstructions; so that it appears rather a suggestion of theory than a thing warranted by its actual performance.

Lavoisier M. Lavoisier, or some of the philosophers who were occupied in concert with him in the investigation of the different species of gas which are disengaged from bodies in the course of chemical operations, contrived an air-pump which has great appearance of simplicity, and, being very different from all others, deserves to be taken notice of.

It consists of two barrels *l*, *m*, (fig. 31) with solid pistons *k k*. The pump plate *a b* is pierced at its centre *c* with a hole which branches towards each of the barrels, as represented by *c d*, *c e*. Between the plate and the barrels slides another plate *h i*, pierced in the middle with a branched hole *f d g*, and near the ends with two holes *h h*, *i i*, which go from its under side to the ends. The holes in these two plates are so adjusted, that when the plate *h i* is drawn so far towards *h* that the hole *i* comes within the barrel *m*, the branch *d f* of the hole in the middle plate coincides with the branch *cd* of the upper plate, and the holes *e g* are shut. Thus a communication is established between the barrel *l* and the receiver on the pump-plate, and between the barrel *m* and the external air. In this situation the barrel *l* will exhaust, and *m* will discharge. When the piston of *l* is at its mouth, and that of *m* touches its bottom, the sliding plate is shifted over to the other side, so that *m* communicates with the receiver through the passage *gd*, *ec*, and *l* communicates with the air by the passage *h h*.

Fig. 31.



It is evident that this sliding plate performs the office of four cocks in a very beautiful and simple manner, and that if the pistons apply close to the ends of the barrels so as to expel the whole air, the pump will be perfect. It works, indeed, against the whole pressure of the external air. But this may be avoided by putting valves on the holes *h i*; and these can do no harm, because the air remaining in them never gets back into the barrel till the piston be at the farther end, and the exhaustion of that stroke completed. But the best workmen of London think that it will be incomparably more difficult to execute this cock (for it is a cock of an unusual form), in such a manner that it shall be air-tight and yet move with tolerable ease, and that it is much more liable to wearing loose than common cocks. No accurate accounts have been received of its performance. It must be acknowledged to be ingenious, and it may suggest to an intelligent artist a method of combining common conical cocks upon one axis so as to answer the same purposes much more effectually; for which reason we have inserted it here.

Cuthbertson.

The last improvement which we shall mention, is that published by Mr. Cuthbertson. His pump has given such evidences of its perfection, that we can hardly expect or wish for any thing more complete. But we must be allowed to observe, beforehand, that the same construction was invented, and in part executed, before the end of 1779, by Dr. Daniel Rutherford, then professor of botany in the University of Edinburgh, who was at that time engaged in experiments on the production of air during the combustion of bodies in contact with nitre, and who was vastly desirous of procuring a more complete abstraction of pure aerial matter than could be effected by Mr. Smeaton's pump. The compiler of this article had then an opportunity of perusing the Doctor's dissertation on this subject, which was read in the Philosophical Society of Edinburgh. In this dissertation he appears fully apprised of the existence of pure vital air in the nitrous acid, as its chief ingredient, and as the cause of its most remarkable phenomena, and to want but a step to the discoveries which have ennobled the name of M. Lavoisier. He was particularly anxious to obtain *apart* this distinguishing ingredient in its composition, and, for this purpose, to abstract completely from the vessel in which he subjected it to examination, every particle of elastic matter. The writer of this article proposed to him to cover the bottom of Mr. Smeaton's piston with some clammy matter, which should take hold of the bottom valve, and *start it* when the piston is drawn up. A few days after, the Doctor showed him a drawing of a pump, having a conical metal valve in the bottom, furnished with a long slender wire, sliding in the inside of the piston-rod with a gentle friction, sufficient for lifting the valve, and secured against all chance of failure by a spring a-top, which took hold of a notch in the inside of the piston-rod about a quarter of an inch from the lower end, so as certainly to lift the valve during the last quarter of an inch of the piston's motion. Being an excellent mechanic, he had executed a valve on this principle, and was fully satisfied with its performance. But having already confirmed his doctrines respecting the nitrous acid by incontrovertible experiments, his wishes to improve the air-pump lost their incitement, and he thought no more of it; and not long after this the ardour of the philosophers of the Teylerian Society at Haerlem and Amsterdam excited the efforts of Mr. Cuthbertson, their instrument maker, to the same purpose, and produced the most perfect air-pump that has yet appeared. We shall give a description of it, and an account of its performance, in the inventor's own words.

Cuthbertson's Air-Pump.—On fig. 32 is a perspective view of Cuthbertson's pump, with its two principal gages screwed into their places. These need not be used together, except in cases where the utmost exactness is required. In common experiments one of them is removed, and a stop-screw put in its place. When the pear-gage is used, a small round plate, on which the receiver may stand, must be first screwed into the hole at A; but this hole is stopped on other occasions with a screw. When all the three gages are used, and the receiver is exhausted, the stop-screw B, at the bottom of the pump, must be unscrewed, to admit the air into the receiver; but when they are not all used, either of the other stop-screws will answer this purpose.

Fig. 32.

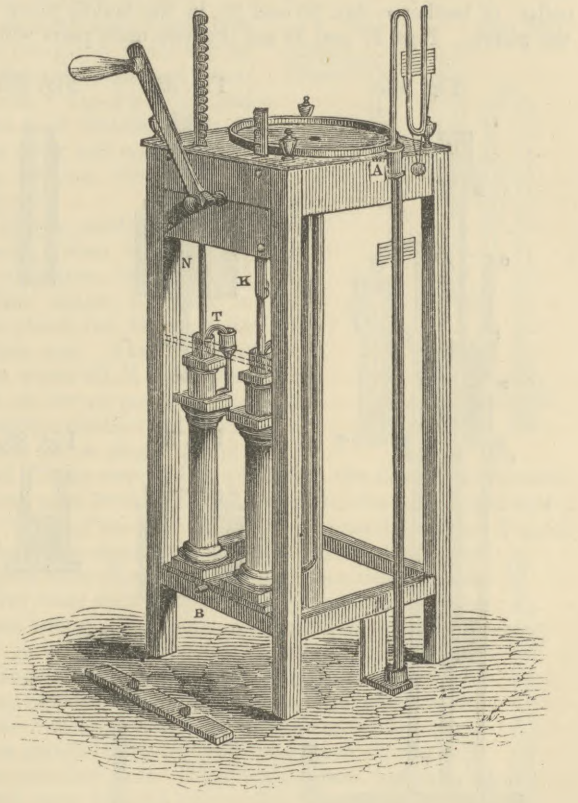


Fig 33 represents a cross bar for preventing the barrels from being shaken by working the pump or by any accident. Its place in fig. 32 is represented by the dotted lines.

Fig. 33.

Fig. 34 is a section of one of the barrels, with all its internal parts; and figs. 35, 36, 37, and 38, are different parts of the piston, proportioned in size to one another.[1]

In fig. 34 CD represents the barrel, F the collar of leathers, G a hollow cylindrical vessel to contain oil, R is also an oil-vessel to receive the oil which is drawn, along with the air, through the hole *a a*, when the piston is drawn upwards; and, when this is full, the oil is carried over with the air, along the tube T, into the oil-vessel G; *c c* is a wire which is driven upwards from the hole *a a* by the passage of the air; and as soon as this has escaped, it falls down again by its own weight, shuts up the hole, and prevents all return of the air into the barrel. At *d d* are fixed two pieces of brass, to keep the wire *c c* in a vertical direction, that it may accurately shut the hole. H is a cylindrical wire or rod which carries the piston I, and is made hollow to receive a long wire *g g*, which opens and shuts the hole L; and on the other end of the wire O is screwed a nut, which, by stopping in the narrowest part of the hole, prevents the wire from being driven up too far. This wire and screw are more clearly seen in figs. 35 and 39; they slide in a collar of leather *r*, figs. 35 and 38, in the middle piece of the piston. Figs. 37 and 38 are the two main parts which compose the piston, and when the pieces 36 and 39 are added to it the whole is represented by fig. 35. Fig. 38 is a piece of brass of a conical form, with a shoulder at the bottom. A long hollow screw is cut in it, about two-thirds of its length, and the remainder of the hole, in which there is no screw, is of about the same diameter with the screwed part, except a thin plate at the end, which is of a width exactly equal to the thickness of *g g*, fig. 34. That part of the inside of the conical brass in which no thread is cut, is filled with oiled leathers with holes through which *g g* can slide stifly. There is also a male screw with a hole in it, fitted to *g g*, serving to compress the leathers *r*. In fig. 37, *a a a a* is the outside of the piston, the inside of which is turned so as exactly to fit the outside of fig. 38; *b b* are round leathers about 60 in number, *c c* is a circular piece of brass of the size of the leathers, and *d d* is a screw serving to compress them. The screw at the end of fig. 36 is made to fit the screw in fig. 38. Now if fig. 39 be pushed into fig. 38, this into fig. 37, and fig. 36 be screwed into the end of fig. 38, these will compose the whole of the piston, as represented in fig. 34. H, in fig. 34, represents the same part as H in fig. 35, and is that to which the rack is fixed. If, therefore, this be drawn upwards, it will cause fig. 38 to shut close into fig. 37, and drive out the air above it; and when it is pushed downwards it will open as far as the shoulder *a a* will permit, and suffer air to pass through. AA (fig. 40) is the receiver plate, BB is a long square piece of brass, screwed into the under side of the plate, through which a hole is drilled corresponding to that in the centre of the receiver-plates and with three female screws *a*, *b*, *c*.

Fig. 34.

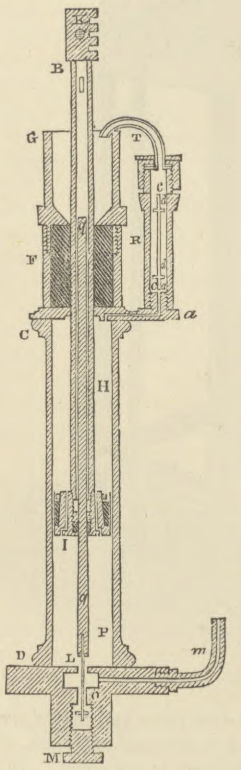

Fig. 35.

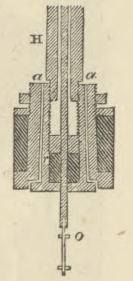

Fig. 36.

Fig. 37.

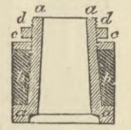

Fig. 38.

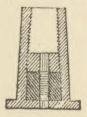

Fig 39.

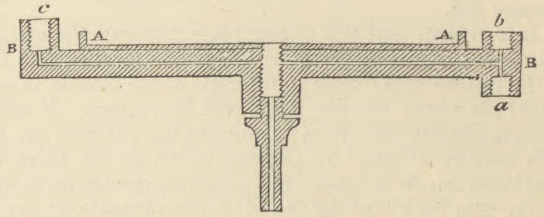
Fig. 40.



The rarefaction of the air in the receiver is effected as follows. Suppose the piston at the bottom of the barrel. The inside of the barrel, from the top of the piston to *a*, (fig. 34) contains common air. When the rod is drawn up, the outer part of the piston sticks fast in the barrel till the conical part connected with the rod shuts the conical hole, and its shoulder applies close to its bottom. The piston is now shut, and therefore the *whole* is drawn up by the rack-work, driving the air before it through the hole *a c*, into the oil-vessel at R, and out into the room by the tube T. The piston will then be at the top of the barrel at *a*, and the wire *g g* will stand nearly as represented in the figure just raised from the hole L, and prevented from rising higher by the nut O. During this motion the air will expand in the receiver, and come along the bent tube *m* into the barrel. Thus the barrel will be filled with air, which, as the piston rises, will be rarefied in proportion as the capacity of the receiver, pipes, and barrel, is to the barrel alone. When the piston is moved down again by the rack-work, it will force the conical part (fig. 38) out of the hollow part (fig. 37) as far as the shoulders *a a*; fig. 35 will rest on *a a* (fig. 37) which will then be so far open as to permit the air to pass freely through it, while at the same time the end of *g g* is forced against the top of the hole, and shuts it, in order to prevent any air from returning into the receiver. Thus the piston, moving downwards, suffers tne air to pass out between the sides of figs. 37 and 38; and, when it is at the bottom of the barrel, will have the column of air above it; and, consequently, when drawn upwards it will shut, and drive out this air, and, by opening the hole L at the same time, will give a free passage to more air from the receiver. This process being continued, the air of the receiver will be rarefied as far as its expansive power will permit. For in this machine there are no valves to be forced open by the elasticity of the air in the receiver, which at last it is unable to effect. There is therefore nothing to prevent the air from expanding to its utmost degree.

---

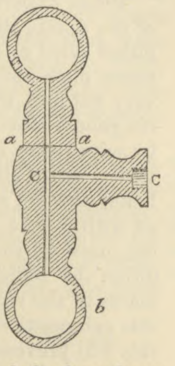
[1] The piston and barrel are 1·65 inches in diameter, in proportion to which the scale is drawn. Figures 35, 36, 37, and 38, are, however, of double size.

It may be suspected here, that as the air must escape through the discharging passage *ac*, fig. 34, against the pressure of a column of oil and the weight of the wire, there will remain in this passage a quantity of air of considerable density, which will expand again into the barrel during the descent of the piston, and thus put a stop to the progress of rarefaction. This is the case in Mr. Smeaton's pump, and all which have valves in the piston. But it is the peculiar excellency of this pump, that whatever be the density of the air remaining in *ac*, the rarefaction will still go on. It is worth while to be perfectly convinced of this. Let us suppose that the air contained in *ac* is $\frac{1}{100}$th part of the common air which would fill the barrel, and that the capacity of the barrel is equal to that of the receiver and passages, and that the air in the receiver and barrel is of the same density, the piston being at the bottom of the barrel: the barrel will therefore contain $\frac{10}{1000}$ parts of its natural quantity, and the receiver $\frac{10}{1000}$. Now let the piston be drawn up. No air will be discharged at *ac*, because it will contain the whole air which was in the barrel, and which has now collapsed into its ordinary bulk. But this does not in the least hinder the air of the receiver from expanding into the barrel, and diffusing itself equally between both. Each will now contain $\frac{5}{1000}$ of their ordinary quantity when the piston is at the top, and *ac* will contain $\frac{1}{100}$ as before, or $\frac{10}{1000}$. Now push down the piston. The hole L is instantly shut, and the air in *ac* expands into the barrel, and the barrel now contains $\frac{15}{1000}$. When the piston has reached the bottom, let it be again drawn up. There will be $\frac{5}{1000}$ discharged through *c*, and the air in the receiver will again be equally distributed between it and the barrel. Therefore the receiver will now contain $\frac{2\frac{1}{2}}{1000}$. When the piston reaches the bottom, there will be $\frac{12\frac{1}{2}}{1000}$ in the barrel. When again drawn up to the top, there will be $\frac{2\frac{1}{2}}{1000}$ discharged, and the receiver will contain $\frac{1\frac{1}{4}}{1000}$; and when the piston reaches the bottom, there will be $\frac{11\frac{1}{4}}{1000}$. At the next stroke the receiver will contain only $\frac{0\cdot\frac{5}{8}}{1000}$, &c. &c.

Thus it appears, that notwithstanding the $\frac{10}{1000}$ which always expands back again out of the hole *ac* into the barrel, the rarity of the air in the receiver will be doubled at every stroke. There is therefore no need of a subsidiary air-pump at *c*, as in the American air-pump, and in the Swedish attempt to improve Smeaton's.

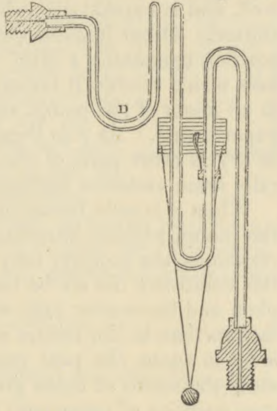
In using this air-pump no particular directions are necessary, nor is any peculiar care necessary for keeping it in order, except that the oil-vessel G be always kept about half full of oil. When the pump has stood long without being used, it will be proper to draw a table-spoonful of olive-oil through it, by pouring it into the hole in the middle of the receiver-plate when the piston is at the bottom of the barrel. Then by working the piston, the oil will be drawn through all the parts of the pump, and the surplus will be driven through the tube T into the oil-vessel G. Near the top of the piston rod at H, there is a hole which lets some oil into the inside of the rod, which gets at the collar of leathers *rr*, and keeps the wire *gg* air-tight.

Fig. 41.



When the pump is used for condensation at the same time that it rarifies, or separately, the piece containing the bent tube T must be removed, and fig. 41 put into its place, and fixed by its screws. Fig. 41, as drawn in the plate, is intended for a double-barrelled pump. But for a single barrel only one piece is used, represented by *b a a*, the double piece being cut off at the dotted line *a a*. In this piece is a female screw to receive the end of a long brass tube, to which a bladder (if sufficient for the experiment of condensation,) or a glass, properly secured for this purpose, must be screwed. Then the air which is abstracted from the receiver on the pump-plate will be forced into the bladder or glass. But if the pump be double, the apparatus fig. 41 is used, and the long brass tube screwed on at *c*.[1]

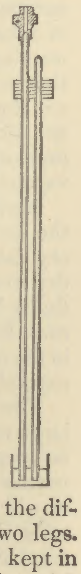
Fig. 42.



Figs. 42 and 43 represent the two gages, which will be sufficiently explained afterwards. Fig. 42 is screwed into *b*, or into the screw at the other end *c*, fig. 40, and fig 43 into the screw *a*, fig. 40.

If it be used as a single pump, either to rarefy or to condense, the screw K, which fastens the rack to the piston rod H, must be taken out. Then turning the winch till H is depressed as low as possible, the machine will be fitted to exhaust as a single pump; and if it be required to condense, the directions formerly given must be observed with regard to the tube T, and fig. 41.

Fig. 43.



"I took," says Mr. Cuthbertson, "two barometer tubes of an equal bore with that fixed to the pump. These were filled with mercury four times boiled. They were then compared, and stood exactly at the same height. The mercury in one of them was boiled in it four times more, without making any change in their height; they were therefore judged very perfect. One of these was immersed in the cistern of the pump gage, and fastened in a position parallel to it, and a sliding scale of one inch was attached to it. This scale, when the gage is used, must have its upper edge set equal with the surface of the mercury in the boiled tube after exhaustion, and the difference between the height of the mercury in this and in the other barometer tube may be observed to the $\frac{1}{100}$ of an inch; and being close together, no error arises from their not being exactly vertical, if they are only parallel. This gage will be better understood by inspecting fig. 43.

"I used a second gage, which I shall call a double syphon. (See fig. 42.) This was also prepared with the utmost care. I had a scale for measuring the difference between the height of the columns in the two legs. It was an inch long, and divided as the former, and kept in a truly vertical position by suspending it from a point with a weight hung to it, as represented in the figure. Upon comparing these two gages, I always found them to indicate the same degree of rarefaction. I also used a pear-gage, though the most imperfect of all, in order to repeat the curious experiments of Mr. Nairne and others."

---

[1] An air-pump of this description is by far too delicate to be employed without risk of injury in experiments on condensed air.

When experiments require the utmost rarefying power of the pump, the receiver must not be placed on leather, either oiled or soaked in water, as is usually done. The pump plate and the edge of the receiver must be ground very flat and true, and this with very fine emery, that no roughness may remain. The plate of the pump must then be wiped very clean and very dry, and the receiver rubbed with a warm cloth till it become electrical. The receiver being now set on the plate, hog's lard, either alone or mixed with a little oil which has been cleared of water by boiling, must be smeared round its outside edge. In this condition the pump will rarefy its utmost, and what still remains in the receiver will be permanent air. Or a little of this composition may be thinly smeared on the pump plate; this will prevent all risk of scratching it with the edge of the receiver. Leather of very uniform thickness, long dried before a fire, and well soaked in this composition, which must be cleared of all water by the first boiling, will answer very well, and is expeditious, when receivers are to be frequently shifted. Other leathers should be at hand soaked in a composition containing a little rosin. This gives it a clamminess which renders it impermeable to air, and is very proper at all joints of the pump, and all apparatus for pneumatic experiments. As it is impossible to render the pear-gage as dry as other parts of the apparatus, there will be generally some variation between this and the other gages.

When it is only intended to show the utmost power of the pump, without intending to ascertain the quality of the residuum, the receiver may be set on wet leather. If, in this condition, the air be rarefied as far as possible, the syphon and barometer gage will indicate a less degree of rarefaction than in the former experiments. But when the air is let in again, the pear gage will point out a rarefaction some thousands of times greater than it did before. If the true quantity of permanent air after exhaustion be required, the pear gage will be nearest the truth; for when the air is rarefied to a certain degree, the moistened leather emits an expansible fluid, which, filling the receiver, forces out the permanent air; and the two first gages indicate a degree of exhaustion which relates to the whole elastic matter remaining in the receiver, viz. to the expansible fluid together with the permanent air; whereas the pear gage points out the degree of exhaustion, with relation to the permanent air alone, which remains in the receiver; for by the pressure of the air admitted into the receiver, the elastic vapour is reduced to its former bulk, which is imperceptible.

Many bodies emit this elastic fluid when the pressure of the air is much diminished; a piece of leather, in its ordinary damp state, about an inch square, or a bit of green or dry wood, will supply this for a great while. When such fluids have been generated in any experiments, the pump must be carefully cleared of them, for they remain not only in the receiver, but in the barrels and passages, and will again expand when the exhaustion has been carried far.

The best method of clearing the pump is to take a very large receiver, and, using every precaution, to exhaust it as far as possible. Then the expansible matter lurking in the barrels and passes will be diffused through the receiver also, or will be carried off along with its air. It will be as much rarer than it was before, as the aggregate capacity of the receiver, barrels and passes is larger than that of the two last.

The performance of the pump may be judged of from the four following experiments: The two gages being screwed into their places, and the hole in the receiver-plate shut up the pump was made to exhaust as far as it could. The mercury in the legs of the syphon was only $\frac{1}{40}$ of an inch out of the level, and that in the boiled barometer-tube $\frac{1}{40}$ of an inch higher than in the one screwed to the pump. A standard barometer then stood at 30 inches, and therefore the pump rarefied the permanent air 1200 times. This is twice as much as Mr. Nairne found Mr. Smeaton's do in its best state. Mr. Cavallo seems disposed to give a favourable account of Haas and Hurter's pump, and it appears never to have exceeded 600 times. Mr. Cuthbertson has often found the mercury within $\frac{1}{100}$ of an inch of the level in the syphon-gage, indicating a rarefaction of 3000.[1]

To one end of a glass tube, two inches diameter and thirty inches long, was fitted a brass cap and collar of leather, through which a wire was inserted, reaching about two inches within the tube. This was connected with the conductor of an electric machine. The other end was ground flat and set on the pump plate. When the gages indicated a rarefaction of 300, the light became steady and uniform, of a pale colour, though a little tinged with purple; at 600 the light was of a pale dusky white; when 1200 it disappeared in the middle of the tube, and the tube conducted so well that the prime conductor only gave sparks so faint and short as to be scarcely perceptible. After taking off the tube, and making it as dry as possible, it was again connected with the conductor, which was giving sparks two inches long. When the air in it was rarefied ten times, the sparks were of the same length. Sometimes a pencil of light darted along the tube. When the rarefaction was 20, the spark did not exceed an inch, and light streamed the whole length of the tube. When the rarefaction was 30, the sparks were half an inch, and the light rushed along the tube in great streams. When the rarefaction was 100, the sparks were about $\frac{1}{8}$ long, and the light filled the tube in an uninterrupted body. When 300, the appearances were as before. When 600, the sparks were $\frac{1}{10}$, and the light was of a faint white colour in the middle, but tinged with purple toward the ends. When 1200, the light was hardly perceptible in the middle, and was much fainter at the ends than before, but still ruddy. When 1400, which was the most the pump could produce, six inches of the middle of the tube were quite dark, and the ends free of any tinge of red, and the sparks did not exceed $\frac{1}{40}$ of an inch.[2]

The best improvements of the air-pump made in Britain.

We trust that our readers will not be displeased with the preceding history of the air-pump. The occasional information which it gives will be of great use to every person much engaged in pneumatic experiments, and help him in the contrivance and construction of the necessary apparatus. We may be indulged in one remark, that although this noble instrument originated in Germany, all its improvements were made in this kingdom. Both the mechanical and pneumatical principles of Mr. Boyle's construction were extremely different from the German, and, in respect of expedition and conveniency, much superior. The double barrel and gage by Hawkesbee were capital improvements, and on principle; and Mr. Smeaton's method of making the piston work in rarefied air made a complete change in the whole process.

Utility of the air-pump.

Aided by this machine, we can make experiments establishing and illustrating the gravity and elasticity of the air, in a much more perspicuous manner than could be done by the spontaneous phenomena of nature. It allows us in the first place to show the materiality of air in a very distinct manner. Bodies cannot move about in the atmosphere without displacing it. This requires force; and the resistance of the air always diminishes the velocity of bodies moving in it. A heavy body therefore has the velocity of its fall diminished; and if the quantity of air displaced be very great, the diminution will be very considerable. This is the reason why light bodies, such as feathers, fall very slowly. Their moving force is very small, and can therefore displace a great quantity of air only with a very small velocity. But if the same body be dropped *in vacuo*, when there is no air to be displaced, it falls with the whole velocity competent to its gravity. Fig. 44 represents an apparatus by which a guinea and a downy feather are dropped at the same instant. If this be done after the air has been pumped out, the guinea and the feather will be observed to reach the bottom at the same instant.

---

[1] We are disposed to place most reliance on the experiment where $\frac{1}{1200}$ is stated as the limit of exhaustion, particularly as this result corresponds with the best information we have been able to obtain, regarding the performance of various very fine instruments.

[2] Since this article was written, Mr Dunn, a mathematical instrument maker of Edinburgh has invented an air-pump, possessing all the ad-

Fig. 44.

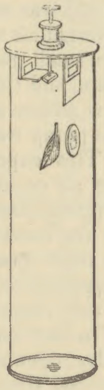


Fig. 45 represents another apparatus for showing the same thing. It consists of two sets of brass vanes put on separate axles, in the manner of windmill sails. One set has their edges placed in the direction of their whirling motion, that is, in a plane to which the axis is perpendicular. The planes of the other set pass through the axis, and they are therefore trimmed so as directly to front the air through which they move. Two springs act upon pins projecting from the axis; and their strength or tensions are so adjusted, that when they are disengaged *in vacuo*, the two sets continue in motion equally long. If they are disengaged in the air, the vanes which beat the air with their planes will stop long before those which cut it edgewise.

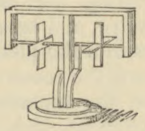
Fig. 45.

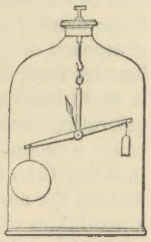


We can now abstract the air most completely from a dry vessel, so as to know the precise weight of the air which filled it. The first experiment we have of this kind, done with accuracy, is that of Dr. Hooke, February 10, 1664, when he found 114 pints of air to weigh 945 grains. One pint of water was $8\frac{7}{32}$ ounces. This gives for the specific gravity of air $\frac{1}{850}$ very nearly.

The effect of air on the weight of bodies immersed in it.

Since we are thus immersed in a gravitating fluid, it follows, that every body preponderates only with the excess of its own weight above that of the air which it displaces; for every body loses by this immersion the weight of the displaced air. A cubic foot loses about 521 grains in frosty weather. We see balloons even rise in the air, as a piece of cork rises in water. A mass of water which really contains 850 pounds will load the scale of a balance with 849 only, and will be balanced by about $849\frac{1}{8}$ pounds of brass. This is evinced by a very pretty experiment, represented in fig. 46. A small beam is suspended within a receiver. To one end of the beam is appended a thin glass or copper ball, close in every part. This is balanced by a small piece of lead hung on the other arm. As the air is pumped out of the receiver, the ball will gradually preponderate, and will regain its equilibrium when the air is re-admitted.

Fig. 46.



Some philosophers have proposed, and even used, a large globe of light make, suspended at a beam, for a barometer. If its capacity be a cubic foot, $1\frac{7}{10}$ grains will indicate the

---

vantages of Mr. Cuthbertson's, with this other in addition, that it is much simpler in its construction. Fig. 1 presents a view of this pump. A A are the barrels. B the pipe leading from them to C the receiver plate, D the barometer gage, E a stop-cock for re-admitting the air, or for attaching a syphon gage, or other piece of apparatus. Fig. 2 is a section of the piston, and of the under part of one of the barrels, shewing the whole of the internal construction; A A, *a a* is the barrel, O N the piston, G I the piston rod containing the rod *r*, which slides in the collar of leathers T, and opens the valve *v e*; in this respect it is precisely the same as Cuthbertson's, but the maker dispenses with all the apparatus at the top of Cuthbertson's barrels, and has only an oiled silk valve S. in the piston, which is exposed to the atmosphere, as in Hook's pump. The exclusion of the atmosphere from the piston valve, the maker considers as unnecessary. From the account previously given of the performance of Cuthbertson's, and of the other pumps described, as well as from his own experience, he is of opinion that the action of the best air pump is stopped, either by the formation of elastic vapour from the oil necessarily present, or from some unknown property of the air itself, long before it has been so much rarefied as to be unable to open the piston valves. His reason for this opinion is, that the capacity of the barrels of any well-constructed pump is several thousand times greater than the space which exists between the valves, when the piston has reached the bottom of the barrel; in short, this may be limited to the small hole S N. For example, in an air-pump, the length of the stroke of which is 12 inches, the diameter of the barrels $2\frac{1}{2}$ in. the diameter of the hole S N $\frac{1}{10}$th of an inch, and its length one inch, the capacity of the hole S N is 7500 times less than the capacity of the barrel, and consequently air 7500 times rarer than the atmosphere when filling the whole barrel, will, by the descent of the piston, become of the same density, but as it is known from the performance of Hook's pump, that air $\frac{1}{100}$th part of the density of the atmosphere has sufficient elastic force to open an oil silk valve, it follows that the pump we have supposed, will exhaust 7425 times, but as this degree of exhaustion has never yet been attained, it is evident that some other reason must be sought for in explanation of this, than the imperfection of the mechanical arrangement. A metallic valve T *p*, may be placed in the piston instead of the oiled silk one, having a projecting point *p* to open it, on the piston reaching the bottom of the barrel, and a space O T filled with oil, to prevent the return of the air during the time which elapses betwixt the commencement of the ascent of the piston and the complete shutting of the valve.

Fig. 1.

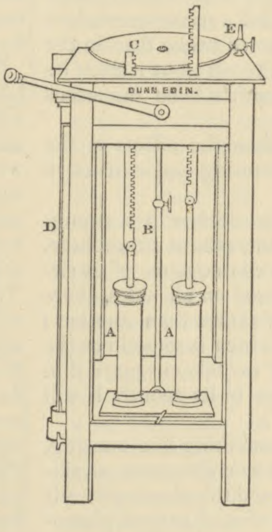


Fig. 2.

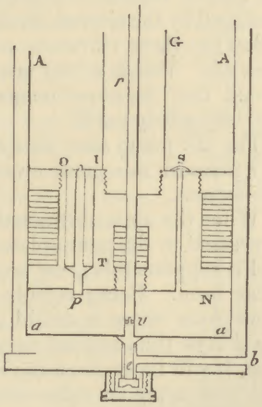


same change that is indicated by $\frac{1}{10}$ of an inch of an ordinary barometer. But a vessel of this size will load a balance too much to leave it sufficiently sensible to small changes of density. Besides, it is affected by heat and cold, and would require a very troublesome equation to correct their effects.

It may perhaps be worth while to attend to this in buying and selling precious commodities; such as pearls, diamonds, silk, and some drugs. As they are generally sold by brass or leaden weights, the buyer will have some advantage when the air is heavy and the barometer high. On the other hand, he will have the advantage in buying gold and mercury when the air is light. It is needless to confine this observation to precious commodities, for the advantage is the same in all in proportion to their levity.

There is a case in which this observation is of consequence to the philosopher: we mean the measuring of time by pendulums. As the accelerating force on a pendulum is not its whole weight, but the excess of its weight over that of the displaced air, it follows that a pendulum will vibrate more slowly in the air than *in vacuo*. A pendulum composed of lead, iron, and brass, may be about 8400 times heavier than the air which it displaces when the barometer is at 30 inches and the thermometer is at 32°, and the accelerating force will be diminished about $\frac{1}{16800}$. This will cause a second pendulum to make about five vibrations less in a day than it would do *in vacuo*. In order therefore to deduce the accelerative power of gravity from the length of a pendulum vibrating in the air, we must make an allowance of 0″.17, or $\frac{17}{100}$ of a second per day, for every inch that the barometer stands lower than 30 inches. But we must also note the temperature of the air; because when the air is warm it is less dense when supporting by its elasticity the same weight of atmosphere, and we must know how much its density is diminished by an increase of temperature. The correction is still more complicated; for the change of density affects the resistance of the air, and this affects the time of the vibration, and this by a law that is not yet well ascertained. As far as we can determine from any experiments that have been made, it appears that the change arising from the altered resistance takes off about 2-5ths of the change produced by the altered density, and that a second pendulum makes but three vibrations a-day more *in vacuo* than in the open air. This is a very unexpected result; but it must be owned that the experiments have neither been numerous nor very nicely made.

The air-pump also allows us to shew the effects of the air's pressure in a great number of amusing and instructive phenomena.

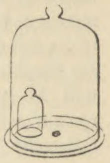
Experiments to shew the effects of the pressure of the air.

When the air is abstracted from the receiver, it is strongly pressed to the pump-plate by the incumbent atmosphere, and it supports this great pressure in consequence of its circular form. Being equally compressed on all sides, there is no place where it should give way rather than another; but if it be thin, and not very round, which is sometimes the case, it will be crushed to pieces. If we take a square thin vial, and apply an exhausting syringe to its mouth, it will not fail being crushed.

As the operation of pumping is something like sucking, many of these phenomena are in common discourse ascribed to suction, a word much abused; and this abuse misleads the mind exceedingly in its contemplation of natural phenomena. Nothing is more usual than to speak of the suction of a syringe, the suction and draught of a chimney, &c. The following experiment puts the true cause of the strong adhesion of the receiver beyond a doubt.

Place a small receiver, or cupping-glass on the pump-plate without covering the central hole, as represented in fig. 47, and cover it with a larger receiver. Exhaust the air from it; then admit it as suddenly as possible. The outer receiver, which, after the rarefaction, adhered strongly to the plate, is now loose, and the cupping-glass will be found sticking fast to it. While the rarefaction was going on, the air in the small receiver also expanded, escaped from it, and was abstracted by the pump. When the external air was suddenly admitted, it pressed on the small receiver, and forced it down to the plate, and thus shut up all entry. The small receiver must now adhere; and there can be no suction, for the pipe of the pump was on the outside of the cupping-glass.

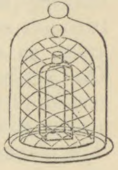
Fig 47.



This experiment sometimes does not succeed, because the air occasionally finds a passage under the brim of the cupping-glass. But if the cupping-glass be pressed down by the hand on the greasy leather or plate, every thing will be made smooth, and the glass will be so little raised by the expansion of its air during the pumping, that it will instantly clap close when the air is re-admitted.

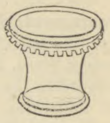
In like manner, if a thin square phial be furnished with a valve, opening from within, but shutting when pressed from without, and if this phial be put under a receiver, and the air be abstracted from the receiver, the air in the phial will expand during the rarefaction, escape through the valve, and be at last in a very rarefied state within the phial. If the air be now admitted into the receiver, it will press on the flat sides of the included phial and crush it to pieces. (See fig. 48.)

Fig. 48.



If a piece of wet ox-bladder be laid over the top of a receiver whose orifice is about four inches wide, and the air be exhausted from within it, the incumbent atmosphere will press down the bladder into a hollow form, and then burst it inward with a prodigious noise. (See fig. 49.) Or if a piece of thin flat glass be laid over the receiver, with an oiled leather between them to make the juncture air-tight, the glass will be broken downwards. This must be done with caution, because the pieces of glass sometimes fly about with great force.[1]

Fig. 49.



If there be formed two hemispherical cups of brass, with very flat thick brims, and one of them be fitted with a neck and stopcock, as represented by fig. 50, the air may be abstracted from them by screwing the neck into the hole in the pump-plate. To prevent the insinuation of air, a ring of oiled leather may be put between the rims. Now unscrew the sphere from the pump, and fix hooks to each, and suspend them from a strong nail, and hang a scale to the lowest. It will require a considerable weight to separate them; namely, about 15 pounds for every square inch of the great circle of the sphere. If this be four inches diameter, it will require near 190 pounds. This pretty experiment was first made by Otto Guericke, and on a very great scale. His sphere was of a large size, and when exhausted, the hemispheres could not be drawn asunder by 20 horses. It was exhibited, along with many others equally curious and magnificent, to the emperor of

Fig. 50.

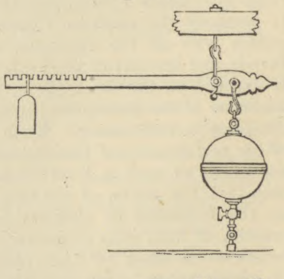


Fig. 51.

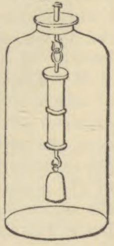


---

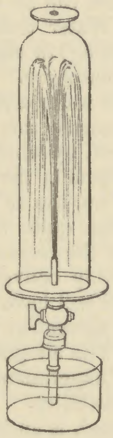
[1] Such experiments should never be performed with a good pump; for fragments of the glass will get into the pump and impair its working, in spite of the utmost skill of the operator.

Experiments on air.

Germany and his court, at the breaking up of the diet of Ratisbon in 1654. If a loaded syringe be suspended by its piston from the hook in the top plate of the receiver, as in fig. 51, and the air be abstracted by the pump, the syringe will gradually descend (because the elasticity of the air, which formerly balanced the pressure of the atmosphere, is now diminished by its expansion, and is therefore no longer able to press the syringe to the piston), and it will at last drop off. If the air be admitted before this happens, the syringe will immediately rise again.

Screw a short brass pipe into the neck of a transporter, on which is set a tall receiver, and immerse it into a cistern of water. On opening the cock, the pressure of the air on the surface of the water in the cistern will force it up through the pipe, and cause it to spout into the receiver with a strong jet, because there is no air within to balance by its elasticity the pressure of the atmosphere. (See fig. 52.)

Fig. 52.

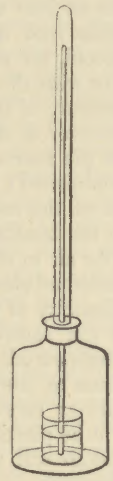


By this pressure the gage of an air-pump acts

It is in the same way that the gage of the air-pump performs its office. The pressure of the atmosphere raises the mercury in the gage till the weight of the mercury, together with the remaining elasticity of the air in the receiver, are in equilibrio with the whole pressure of the atmosphere: therefore the height and weight of the mercury in the gage is the excess of the weight of the atmosphere above the elasticity of the included air; and the deficiency of this height from that of the mercury in the Toricellian tube is the measure of this remaining elasticity.

If a Toricellian tube be put under a tall receiver, as shown in fig. 53, and the air be exhausted, the mercury in the tube will descend, while that in the gage will rise; and the sum of their heights will always be the same, that is, equal to the height in an ordinary barometer. The height of the mercury in the receiver is the effect and measure of the remaining elasticity of the included air, and the height in the pump-gage is the unbalanced pressure of the atmosphere. This is a very instructive experiment, perfectly similar to Mr. Auzout's, and completely establishes and illustrates the whole doctrine of atmospheric pressure.

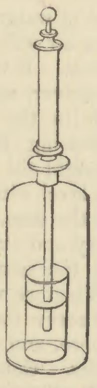
Fig. 53.



Water rises in pumps.

We get a similar illustration and confirmation (if such a thing be now needed) of the cause of the rise of water in pumps, by screwing a syringe into the top plate of a receiver, which syringe has a glass pipe plunging into a small cup of water. (See fig. 54.) When the piston-rod is drawn up, the water rises in the glass pipe, as in any other pump, of which this is a miniature representation. But if the air has been previously exhausted from the receiver, there is nothing to press on the water in the little jar; and it will not rise in the glass pipe though the piston of the syringe be drawn to the top.

Fig. 54.



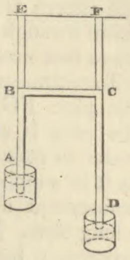
It moves in syphons.

Analogous to the rise of water in pumps is its rise and motion in syphons. Suppose a pipe ABCD, fig. 55, bent at right angles at B and C, and having its two ends immersed in the cisterns of water A and D. Let the leg CD be longer than the leg BA, and let the whole be full of water.

Experiments on air.

The water is pressed upwards at A with a force equal to the weight of the column of air EA reaching to the top of the atmosphere; but it is pressed downwards by the weight of the column of water BA. The water at D is pressed downwards by the weight of the column CD, and upwards by the weight of the column of air FD reaching to the top of the atmosphere. The two columns of air differ very little in their weight, and may without any sensible error be considered as equal. Therefore there is a superiority of pressure downwards at D, and the water will flow out there. The pressure of the air will raise the water in the leg AB, and thus the stream will be kept up till the vessel A is emptied as low as the orifice of the leg BA, provided that the height of AB is not greater than what the pressure of the atmosphere can balance, that is, does not exceed 32 or 33 feet for water, 30 inches for mercury, &c.

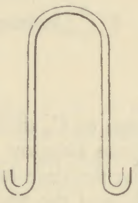
Fig. 55.



A syphon then will always run from that vessel whose surface is highest; the form of the pipe is indifferent, because the hydrostatical pressures depend on the vertical height only. It must be filled with water by some other contrivance, such as a funnel, or a pump applied a-top; and the funnel must be stopped up, otherwise the air would get in, and the water would fall in both legs.

If the syphon have equal legs, and be turned up at the ends, it will remain full of water, and be ready for use. One end of it need only be dipped into any vessel of water, and the water will then flow out at the other end of the syphon. This is called the Wirtemberg syphon, and is represented in fig. 56.

Fig. 56.

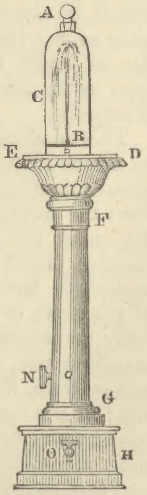


The syphon fountain.

What is called the *syphon fountain*, constructed on this principle, is shown in fig. 57, where AB is a tall receiver, standing in a wide bason DE, which is supported on the pedestal H, by the hollow pillar FG. In the centre of the receiver is a jet pipe C, and in the top a ground stopper A. Near the base of the pillar is a cock N, and in the pedestal is another cock O.

Fill the bason DE with water within half an inch of the brim. Then pour in water at the top of the receiver (the cock N being shut) till it is about half full, and then put in the stopper. A little water will run out into the vessel DE. But before it runs over, open the cock N, and the water will run into the cistern H; and by the time that the pipe C appears above water, a jet will rise from it, and continue as long as water is supplied from the bason DE. The passage into the base cistern may be so tempered by the cock N that the water within the receiver shall keep at the same height, and what runs into the base may be received from the cock O into another vessel, and returned into DE, to keep up the stream.

Fig. 57



Manner of its construction and operation.

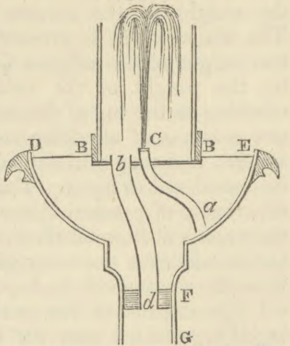
This pretty philosophical toy may be constructed in the following manner. BB, (fig. 58,) is the ferril or cap into which the receiver is cemented. From its centre descends the jet pipe C*a*, sloping outwards, to give room for the discharge pipe *bd* of larger diameter, the lower extremity of which *d* fits tightly into the top of the hollow pillar FG.

The operation of the toy is easily understood. Suppose the distance from C to H (fig. 57,) three feet, which is about $\frac{1}{11}$ of the height at which the atmosphere would support a column of water. The water poured into AB would descend through FG (the hole A being shut) till the air has

Experiments on air.

expanded $\frac{1}{10}$, and then it would stop. If the pipe C*a* be now opened, the pressure of the air on the surface of the water in the cistern DE will cause it to spout through C to the height of three feet nearly, and the water will continue to descend through the pipe FG. By tempering the cock N so as to allow the water to pass through it as fast as it is supplied by the jet, the amusement may be continued a long time. It will stop at last, however; because, as the jet is made into rarefied air, a little air will be extricated from the water, which will gradually accumulate in the receiver, and diminish its rarefaction, which is the moving cause of the jet. This indeed is an inconvenience felt in every employment of syphons, so much the more remarkably as their top is higher than the surface of the water in the cistern of supply.

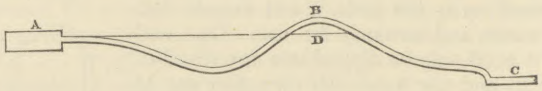
Fig. 58.



Syphons are often used thus.

Cases of this employment of a syphon are not unfrequent. When water collected at A (fig. 59,) is to be conducted in a pipe to C, situated in a lower part of the country, it sometimes happens that the intervening ground is higher than the fountain-head as at B. A forcing pump is erected at A, and the water forced along the pipe. Once it runs out at C, the pump may be removed, and the water will continue to run on the syphon principle, provided BD do not exceed 33 feet. But the water in that part of the conduit which is above the horizontal plane AD, is in the same state as in a receiver of rarefied air, and gives out some of the air which is united with it. This gradually accumulates in the elevated part of the conduit, and at last chokes it entirely.

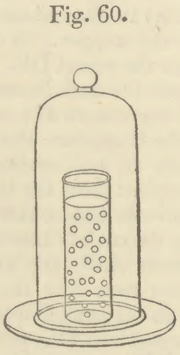
Fig. 59.



The air-pump discovers the combination of air with water, &c.

This combination of air with water is very distinctly seen by means of the air-pump. If a small glass containing cold water, fresh drawn from the spring, be exposed, as in fig. 60, under the receiver, and the air rarefied, small bubbles will be observed to form on the inner surface of the glass, or on the surface of any body immersed in it, which will increase in size, and then detach themselves from the glass and reach the top; as the rarefaction advances, the whole water begins to show very minute air-bubbles rising to the top; and this appearance will continue for a very long time, till it be completely disengaged. Warming the water will occasion a still farther separation of air, and a boiling heat will separate all that can be disengaged. The reason assigned for these air-bubbles first appearing on the surface of the glass, &c. is, that air is attracted by bodies, and adheres to their surface. This may be so. But it is more probably owing to the attraction of the water for the glass, which causes it to quit the air which it held in solution, in the same manner as we see it happen when it is mixed with spirits-of-wine, with vitriolic acid, &c., or when salts or sugar are dissolved in it. For if we pour out the water which has been purged of air by boiling *in vacuo*, and fill the glass with fresh water, we shall observe the same thing, although a film of the purified water was left adhering to the glass. In this case there can be no air adhering to the glass.

Fig. 60.



Experiments on air.

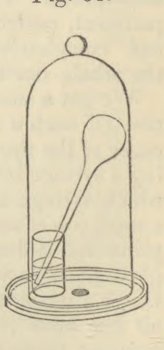
Water thus purged of air by boiling (or even without boiling) *in vacuo*, will again absorb air when exposed to the atmosphere. The best demonstration of this is to fill with this water a phial, leaving about the size of a pea not filled. Immerse this in a vessel of water, with the mouth undermost, by which means the air-bubble will mount up to the bottom of the phial. After some days standing in this condition, the air-bubble will be completely absorbed, and the vessel quite filled with water. A glass of beer placed under the receiver and treated in the same way will be almost wholly converted into froth by the escape of its fixed air, and will have lost entirely the prickling smartness which is so agreeable, and become quite vapid.

Experiments illustrative of the elasticity and expansibility of the air.

The air-pump gives us, in the next place, a great variety of experiments illustrative of the air's elasticity and expansibility. The very operation of exhaustion, as it is called, is an instance of its great expansibility. But this is not palpably exhibited to view. The following experiments show it most distinctly. First, put a flaccid bladder, of which the neck is firmly tied with a thread, under a receiver, and work the pump. The bladder will gradually swell, and will even be fully distended. Upon readmitting the air into the receiver, the bladder gradually collapses again into its former dimensions; while the bladder is flaccid, the air within it is of the same density and elasticity with the surrounding air, and its elasticity balances the pressure of the atmosphere. When part of the air of the receiver is abstracted, the remainder expands so as still to fill the receiver; but by expanding, its elasticity is plainly diminished; for we see by the fact, that the elasticity of the air of the receiver no longer balances the elasticity of that in the bladder, as it no longer keeps it in its dimensions. The air in the bladder expands also; it expands till its diminished elasticity is again in equilibrio with the diminished elasticity of the air in the receiver; that is, till its density is the same. When all the wrinkles of the bladder have disappeared, its air can expand no more, although we continue to diminish the elasticity of the air of the receiver by further rarefaction. The bladder now tends to burst; and if it be pierced by a point or knife fastened to the slip-wire, the air will rush out, and the mercury descend rapidly in the gage.

If a phial or tube (fig. 61) be partly filled with water, and immersed in a vessel of water with the mouth downwards, the air will occupy the upper part of the phial. If this apparatus be put under a receiver, and the air be abstracted, the air in the phial will gradually expand, allowing the water to run out by its weight till the surface of the water be on a level within and without. When this is the case, we must grant that the density and elasticity of the air in the phial is the same with that in the receiver. When we work the pump again, we shall observe the air in the phial expand still more, and come out of the water in bubbles. Continuing the operation, we shall see the air continually escaping from the phial; when this is over, it shows that the pump can rarefy no more. If we now admit the air into the receiver, we shall see the water rise into the phial, and at last almost completely fill it, leaving only a very small bubble of air at the top. This bubble had expanded so as to fill the whole phial.

Fig. 61.



Every one must have observed a cavity at the big end of an egg between the shell and the white. The white and

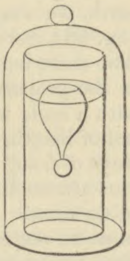
Experiments on air.

yolk are contained in a thin membrane or bladder which adheres loosely to the shell, but is detached from it at that part; and this cavity increases by keeping the egg in a dry place. One may form a judgment of its size, and therefore of the freshness of the egg, by touching it with the tongue; for the shell, where it is not in contact with the contents, will presently feel warm, being quickly heated by the tongue, whilst the rest of the egg will feel cold.

If a hole be made in the opposite end of the egg, and it be set on a little tripod, and put under a receiver, the expansion of the air in the cavity of the egg will force the contents through the hole till the egg be quite emptied; or, if nearly one-half of the egg be taken away at the other end, and the white and yolk taken out, and the shell be put under a receiver, and the air abstracted, the air in the cavity of the egg will expand, gradually detaching the membrane from the shell, till it causes it to swell out, and gives the whole the appearance of an entire egg. In like manner shrivelled apples and other fruits will swell in vacuo by the expansion of the air confined in their cavities.

If a piece of wood, a twig with green leaves, charcoal, plaster of Paris, &c. be kept under water in vacuo, a prodigious quantity of air will be extracted; and if we readmit the air into the receiver, it will force the water into the pores of the body. In this case the body will not swim in water as it did before, showing that the vegetable fibres are specifically heavier than water. It is found, however, that the air contained in the pith and bark, such as cork, is not all extricated in this way; and that much of it is contained in vesicles which have no outlet; being secreted into them in the process of vegetation, as it is secreted in the air-bladder of fishes, where it is generally found in a pretty compressed state, considerably denser than the surrounding air. The air-bladder of a fish is surrounded by circular and longitudinal muscles, by which the fish can compress the air still further; and, by ceasing to act with them, allow it to swell out again. It is in this manner that the fish can suit its specific gravity to its situation in the water, so as to have no tendency either to rise or sink; but if the fish be put into the receiver of an air-pump, the rarefaction of the air obliges the fish to act more strongly with these contracting muscles, in order to adjust its specific gravity; and if too much air has been abstracted from the receiver, the fish is no longer able to keep its air-bladder in the proper degree of compression. It becomes therefore too buoyant, and comes to the top of the water, and is obliged to struggle with its tail and fins in order to get down; frequently in vain. The air-bladder sometimes bursts, and the fish goes to the bottom, and can no longer keep above without the continual action of its tail and fins. When fishes die, they commonly float at top, their contractive action being now at an end. All this may in some degree be illustrated by a small half-blown bladder, to which is appended a bit of lead, just so heavy as to make it sink in water; when this is put under a receiver, and the air abstracted, the bubble will rise to the top; and, by nicely adjusting the rarefaction, it may be kept at any height.

Fig. 62.



The playthings called *Cartesian devils* are similar to this. They are hollow glass figures, having a small aperture in the lower part of the figures, as at the point of the foot; their weight is adjusted so that they swim upright in water. When put into a tall jar filled to the top, and having a piece of leather tied over it, they will sink in the water, by pressing on the leather with the ball of the hand. This, by compressing the water, forces some of it to enter into the figure, and makes it heavier than the water; for which reason it sinks, but rises again on removing the pressure of the hand. (See figs. 63 and 64.)

Experiments on air.

If a half-blown ox-bladder be put into a box, and great weights laid on it, and the whole be put under a receiver, and the air abstracted; the air will, by expanding, lift up the weights, though above an hundred pounds. (See fig. 65.)

Fig. 63.

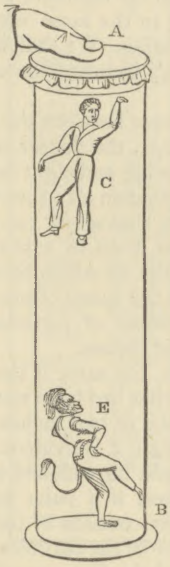


Fig. 64.

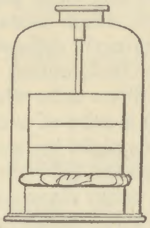
Fig. 65.



Compressibility and expansibility are in no state of the air very dissimilar.

By such experiments, the great expansibility of the air is abundantly illustrated, as its compressibility was formerly by means of the condensing syringe. We now see that the two sets of experiments form an uninterrupted chain; and that there is no particular state of the air's density where the compressibility and expansibility are remarkably dissimilar. Air in its ordinary state expands; because its ordinary state is a state of compression by the weight of the atmosphere; and if there were a pit about thirty-three miles deep, the air at the bottom would probably be as dense as water; and if it were fifty miles deep, it would be as dense as gold, if it did not become a liquid before this depth; nay, if a bottle with its mouth undermost were immersed six miles under water, it would probably be as dense as water; we say probably, for this depends on the nature of its compressibility; that is, on the relation which subsists between the compression and the force which produces it.

Relation between compression and the force producing it.

This is the circumstance of its constitution, which we now proceed to examine; and it is evidently a very important circumstance. We have long ago observed, that the great compressibility and permanent fluidity of air, observed in a vast variety of phenomena, is totally inexplicable, on the supposition that the particles of air are like so many balls of sponge or so many foot-balls. Give to those what compressibility you please, common air could no more be fluid than a mass of clay; it could no more be fluid than a mass of such balls pressed into a box. It may be demonstrated, that before a parcel of such balls, just touching each other, can be squeezed into half their present dimensions, their globular shape will be entirely gone, and each will have become a perfect cube, touching six other cubes with its whole surface; and these cubes will be strongly compressed together, so that motion could never be performed through among them by any solid body without a very great force. Whereas we know that in this state air is just as permeable to every body as the common air that we breathe. There is no way in which we can represent this fluidity to our imagination, but by conceiving air to consist of particles, not only discrete, but distant from each other, and actuated by repulsive forces, or

Experiments on air.

something analogous to them. It is an idle subterfuge, to which some physicists have recourse, saying, that they are kept asunder by an intervening ether, or elastic fluid of any other name. This is only removing the difficulty a step farther off; for the elasticity of this fluid requires the same explanation; and therefore it is necessary, in obedience to the rules of just reasoning, to begin the inquiry here; that is, to determine from the phenomena what is the analogy between the distances of the particles and the repulsive forces exerted at these distances, proceeding in the same way as in the examination of planetary gravitation. We shall learn the analogy by attending to the analogy between the compressing force and the density.

Density explained as applied to air.

For the density depends on the distance between the particles; the nearer they are to each other, the denser is the air. Suppose a square pipe one inch wide and eight inches long, shut at one end, and filled with common air; then suppose a plug so nicely fitted to this pipe that no air can pass by its sides; suppose this piston thrust down to within an inch of the bottom: it is evident that the air which formerly filled the whole pipe now occupies the space of one cubic inch, which contains the same number of particles as were formerly diffused over eight cubic inches.

The condensation would have been the same if the air which fills a cube whose side is two inches had been squeezed into a cube of one inch, for the cube of two inches also contains eight inches. Now, in this case it is evident that the distance between the particles would be reduced to its half in every direction. In like manner, if a cube whose side is three inches, and which therefore contains 27 inches, be squeezed into one inch, the distance of the particles will be one-third of what it was: in general the distance of the particles will be as the cube-root of the space into which they are compressed. If the space be $\frac{1}{8}$, $\frac{1}{27}$, $\frac{1}{64}$, $\frac{1}{125}$, &c. of its former dimensions, the distance of the particles will be $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, $\frac{1}{5}$, &c. Now the term *density*, in its strict sense, expresses the vicinity of the particles; thus, *densi arbores* are trees growing near each other. The measure of this vicinity therefore is the true measure of the density; and when 27 inches of air are compressed into one, we should say that it is three times as dense; but we say, that it is 27 times denser.

Density is therefore used in a sense different from its strictest acceptation; it expresses the comparative number of equidistant particles contained in the same bulk. This is also abundantly precise, when we compare bodies of the same kind, differing in density only; but we also say, that gold is 19 times denser than water, because the same bulk of it is 19 times heavier. This assertion proceeds on the assumption, or the fact, that every ultimate atom of terrestrial matter is equally heavy. A particle of gold may contain more or fewer atoms of matter than a particle of water. In such a case, therefore, the term density has little or no reference to the vicinity of the particles; and is only a term of comparison of other qualities or accidents. But when we speak of the respective densities of the same substance in its different states of compression, the word *density* is strictly connected with vicinity of particles, and we may safely take either of the measures. We shall abide by the common acceptation, and call that air eight times as dense which has eight times as many particles in the same bulk, although the particles are only twice as near to each other.

Analogy.

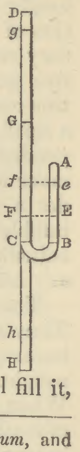
Thus then we see, that by observing the analogy between the compressing force and the density, we shall discover the analogy between the compressing force and the distance of the particles. Now the force which is necessary for compressing two particles of air to a certain vicinity is a proper measure of the elasticity of the particles corresponding to that vicinity or distance; for it balances it, and forces which balance must be esteemed equal. Elasticity is a distinctive name for that corpuscular force which keeps the particles at that distance; therefore observations made on the analogy between the compressing force and the density of air will give us the law of its corpuscular force, in the same way that observations on the simultaneous deflections of the planets towards the sun gives us the law of celestial gravitation.

But the sensible compressing forces which we are able to apply is at once exerted on unknown thousands of particles, whilst it is the law of action of a single particle that we want to discover. We must therefore know the proportion of the numbers of particles on which the compressing force is exerted. It is easy to see, that since the distance of the particles is as the cube root of the density inversely, the number of particles in physical contact with the compressing surface must be as the square of this root. Thus, when a cube of eight inches is compressed into one inch, and the particles are twice as near each other as they were before, there must be four times the number of particles in contact with each of the sides of this cubical inch; or, when we have pushed down the square piston of the pipe spoken of above to within an inch of the bottom, there will be four times the number of particles *immediately* contiguous to the piston, and resisting the compression; and in order to obtain the force really exerted on one particle, and the elasticity of that particle, we must divide the whole compressing force by 4. In like manner, if we have compressed air into $\frac{1}{27}$th of its former bulk, and brought the particles into $\frac{1}{3}$d of their former distance, we must divide the compressing force by 9. In general, if d express the density, $\frac{1}{\sqrt[3]{d}}$ will express the distance x of the particles; $\sqrt[3]{d}$, or $d^{\frac{1}{3}}$ will express the vicinity or real density; and $d^{\frac{2}{3}}$ will express the number of particles acting on the compressing surface; and if f express the accumulated external compressing force, $\frac{f}{d^{\frac{2}{3}}}$ will express the force acting on one particle; and therefore the elasticity of that particle corresponding to the distance x.

Compressibility of air.

We now proceed to consider the experiments by which the law of compression is to be established.[1] In order to examine the compressibility of air that is not rarer than the atmosphere at the surface of the earth, we employ a bent tube or syphon ABCD (fig. 66), hermetically sealed at A, and open at D. The short leg AB must be very accurately divided in the proportion of its solid contents, and fitted with a scale whose units denote equal increments, not of length, but of capacity. There are various ways of doing this; but it requires the most scrupulous attention, and without this the experiments are of no value. In particular, the arched form at A must be noticed. A small quantity of mercury must then be poured into the tube, and passed backwards and forwards till it stands (the tube being held in a vertical position) on a level at B and C. Then we are certain that the included air is of the same density with that of the contiguous atmosphere. Mercury is now poured into the leg DC, which will fill it,

Fig. 66.



---

[1] The first experiments to this purpose were those made by Mr. Boyle, published in his *Defensio Doctrinæ de Aere contra Linum*, and exhibited before the Royal Society the year before. Mariotte made experiments of the same kind, which were published in 1676 in his *Essai sur la Nature de l'Air*, and *Traité des Mouvemens des Eaux*. The most copious experiments are those by Sulzer (*Mem. Berlin*, ix.) those by Fontana (*Opuscula Physico-Mathematica*), and those by Sir George Shuckburgh and General Roy in the *Philosophical Transactions*.

Experiments on air.

suppose to G, and will compress the air into a smaller space AE. Draw the horizontal line EF; the new bulk of the compressed air is evidently AE, measured by the adjacent scale, and the addition made to the compressing force of the atmosphere is the weight of the column GF. Produce GF downwards to H, till FH is equal to the height shown by a Toricellian tube filled with the *same mercury;* then the whole compressing force is HG. This is evidently the measure of the elasticity of the compressed air in AE, for it balances it. Now, pour in more mercury, and let it rise to *g*, compressing the air into A *e*. Draw the horizontal line *e f*, and make *f h* equal to FH; then A *e* will be the new bulk of the compressed air, $\frac{AB}{A e}$ will be its new density, and *h g* will be the measure of the new elasticity. This operation may be extended as far as we please, by lengthening the tube CD, and taking care that it be strong enough to resist the great pressure. Great care must be taken to keep the whole in a constant temperature, because the elasticity of air is greatly affected by heat, and the change by any increase of temperature is different according to its density or compression.

Experiments of Boyle, &c. The experiments of Boyle, Mariotte, Amontons, and others, were not extended to very great compressions, the density of the air not having been quadrupled in any of them; nor do they seem to have been made with very great nicety. It may be collected from them in general, that the elasticity of the air is very nearly proportioned to its density; and accordingly this law was almost immediately acquiesced in, and was called the *Boylean law;* it is accordingly assumed by almost all writers on the subject as exact. Of late years, however, there occurred questions in which it was of importance that this point should be more scrupulously settled, and the former experiments were repeated and extended. The result has been, that the compression of atmospheric air and most other gases increases rather faster than is strictly proportional to the pressure.

Varieties in these experiments. Considerable varieties and irregularities are to be observed in these experiments. It is extremely difficult to preserve the temperature of the apparatus, particularly of the leg AB, which is most handled. A great quantity of mercury must be employed; and it does not appear that philosophers have been careful to have it precisely similar to that in the barometer, which gives us the unit of compressing force and of elasticity. The mercury in the syphon as well as in the barometer should be pure and boiled. If the mercury in the syphon is adulterated with bismuth and tin, which it commonly is to a considerable degree, the compressing force, and consequently the elasticity, will appear greater than the truth. If the barometer has not been nicely filled, it will be lower than it should be, and the compressing force will appear too great, because the unit is too small; and this error will be most remarkable in the smaller compressions.

Heterogeneous nature of the air. The greatest source of error and irregularity in the experiments is the very heterogeneous nature of the air itself. Air is a solvent of all fluids, all vapours, and perhaps of many solid bodies. It is highly improbable that the different compounds shall have the same elasticity, or even the same law of elasticity; and it is well known, that air loaded with water or other volatile bodies, is much more expansible by heat than pure air; nay, it would appear from many experiments, that certain determinate changes both of density and of temperature, cause air to let go the vapours which it holds in solution. Cold causes it to precipitate water, as appears in dew; so does rarefaction, as is seen in the receiver of an air-pump.

The elasticity of air. In general, it appears that the elasticity of air does not increase quite so fast as its density. This will be best seen by the following tables, calculated from the experiments of Mr. Sulzer. The column E in each set of experiments expresses the length of the column GH, the unit being FH, whilst the column D expresses $\frac{AB}{AE}$.

First set.		Second set.		Third set.	
D	E	D	E	D	E
1·000	1·000	1·000	1·000	1·000	1·000
1·100	1·093	1·236	1·224	1·091	1·076
1·222	1·211	1·294	1·288	1·200	1·183
1·375	1·284	1·375	1·332	1·333	1·303
1·571	1·559	1·466	1.417	1·500	1·472
1·692	1·669	1·571	1·515	1·714	1·659
1·833	1·796	1·692	1·647		
2·000	1·958	2·000	1·964	2·000	1·900
2·288	2·130				
2·444	2·375	2·444	2·392	2·400	2·241
3·143	2·936	3·143	3·078	3·000	2·793
3·666	3·391	3·666	3·575		
4·000	3·706			4·000	3·631
4·444	4·035	4·444	4·320		
4·888	4·438				
5·500	4·922	5·500	5·096		
5·882	5·522			6·000	5·297
		7·333	6·694		
				8·000	6·835

There appears in these experiments to be sufficient grounds for calling in question the Boylean law; and the writer of this article thought it incumbent on him to repeat them with some precautions, which probably had not been attended to by Mr. Sulzer. He was particularly anxious to have the air as free as possible from moisture. For this purpose, having detached the short leg of the syphon, which was 34 inches long, he boiled mercury in it, and filled it with mercury boiling hot. He took a tinplate vessel of sufficient capacity, and put into it a quantity of powdered quicklime just taken from the kiln; and having closed the mouth, he agitated the lime through the air in the vessel, and allowed it to remain there all night. He then emptied the mercury out of the syphon into this vessel, keeping the open end far within it. By this means the short leg of the syphon was filled with very dry air. The other part was now joined, and boiled mercury put into the bend of the syphon; and the experiment was then prosecuted with mercury which had been recently boiled, and was the same with which the barometer had been carefully filled.

The results of the experiments are expressed in the following table:

First set.		Second set.		Third set.	
D	E	D	E	D	E
1·000	1·000	1·000	1·000	1·000	1·000
2·000	1·957	2·000	1·920	2·000	1·909
3·000	2·848	3·000	3·839	3·000	2·845
4·000	3·737	4·000	3·726	4·000	3·718
5·500	4·930	5·500	5·000	5·500	5·104
6·000	5·342	6·000	5·452	6·000	5·463
7·620	6·490	7·620	6·775	7·620	6·812

Here it appears again in the clearest manner that the elasticities do not increase as fast as the densities, and the differences are even greater than in Mr. Sulzer's experiments.

The second set contains the results of experiments which

Experiments on air.

were made on very damp air in a warm summer's morning. In these it appears that the elasticities are almost precisely proportional to the densities + a small constant quantity, nearly 0·11, deviating from this rule chiefly between the densities 1 and 1·5, within which limits we have very nearly $D=E^{1\cdot0017}$. As this air is nearer to the constitution of atmospheric air than the former, this rule may be safely followed in cases where atmospheric air is concerned, as in measuring the depths of pits by the barometer.

The third set shows the compression and elasticity of air strongly impregnated with the vapours of camphire. Here the Boylean law appears pretty exact, or rather the elasticity seems to increase a little faster than the density.

Dr. Hooke examined the compression of air by immersing a bottle to great depths in the sea, and weighing the water which got into it without any escape of air. But this method was liable to great uncertainty, on account of the unknown temperature of the sea at great depths.

Mode of examining the elasticity of rarefied air.

Hitherto we have considered only such air as is not rarer than what we breathe; we must take a very different method for examining the elasticity of rarefied air. Let gh (fig. 67,) be a long tube, formed a-top into a cup, and of sufficient diameter to receive another smaller tube af, open at first at both ends. Let the outer tube and cup be filled with mercury, which will rise in the inner tube to the same level. Let af now be stopped at a. It contains air of the same density and elasticity with the adjoining atmosphere. Note exactly the space ab which it occupies. Draw it up into the position of fig. 68, and let the mercury stand in it at the height de, whilst ce is the height of the mercury in the barometer. It is evident that the column de is in equilibrio between the pressure of the atmosphere and the elasticity of the air included in the space ad. And since the weight of ce would be in equilibrio with the whole pressure of the atmosphere, the weight of cd is equivalent to the elasticity of the included air. Whilst therefore ce is the measure of the elasticity of the surrounding atmosphere, cd will be the measure of the elasticity of the included air; and since the air originally occupied the space ab, and has now expanded into ad, we have $\frac{ab}{ad}$ for the measure of its density. N.B. ce and cd are measured by the *perpendicular heights* of the columns, but ab and ad must be measured by their *solid capacities*.

By raising the inner tube still higher, the mercury will also rise higher, and the included air will expand still farther, and we obtain another cd, and another $\frac{ab}{ad}$; and in this manner the relation between the density and elasticity of rarefied air may be discovered.

Fig. 67.

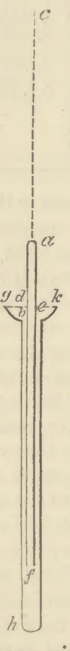


Fig. 68.

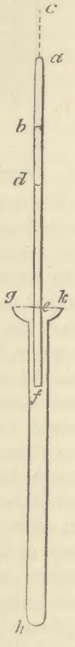

Fig. 69.

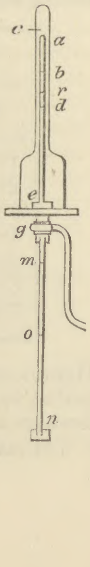


An easier method.

This examination may be managed more easily by means of the air-pump. Suppose a tube ae (fig. 69) containing a small quantity of air ab, set up in a cistern of mercury, which is supported in the tube at the height cb, and let ec be the height of the mercury in the barometer. Let this apparatus be set under a tubulated receiver on the pump-plate, and let gn be the pump-gage, and mn be made equal to ce.

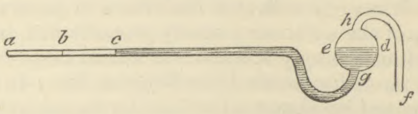
Then, as has been already shown, cb is the measure of the elasticity of the air in ab, corresponding to the bulk ab. Now let some air be abstracted from the receiver. The elasticity of the remainder will be diminished by its expansion; and therefore the mercury in the tube ae will descend to some point d. For the same reason, the mercury in the gage will rise to some point o, and mo will express the elasticity of the air in the receiver. This would support the mercury in the tube ae at the height er, if the space ar were entirely void of air. Therefore rd is the effect and measure of the elasticity of the included air when it has expanded to the bulk ad; and thus its elasticity, under a variety of other bulks, may be compared with its elasticity when of the bulk ab. When the air has been so far abstracted from the receiver that the mercury in ae descends to e, then mo will be the precise measure of its elasticity.

In all these cases it is necessary to compare its bulk ab with its natural bulk, in which its elasticity balances the pressure of the atmosphere. This may be done by laying the tube ac horizontally, and then the air will collapse into its ordinary bulk.

Another method.

Another easy method may be taken for this examination. Let an apparatus $abcdef$ (fig. 70,) be made, consisting of a horizontal tube ae of even bore, a ball dge of a large diameter, and a swan-neck tube hf. Let the ball and part of the tube geb be filled with mercury, so that the tube may be in the same horizontal plane with the surface de of the mercury in the ball. Then seal up the end a, and connect f with an air-pump. When the air is abstracted from the surface de, the air in ab will expand into a larger bulk ac, and the mercury in the pump-gage will rise to some distance below the barometric height. It is evident that this distance, without any farther calculation, will be the measure of the elasticity of the air pressing on the surface dc, and therefore of the air in ae.

Fig. 70.



The most exact mode.

The most exact of all methods is to suspend in the receiver of an air-pump a glass vessel, having a very narrow mouth, over a cistern of mercury, and then abstract the air till the gage rises to some determined height. The difference e between this height and the barometric height determines the elasticity of the air in the receiver and in the suspended vessel. Now, lower down that vessel by the slip-wire till its mouth is immersed into the mercury, and admit the air into the receiver; it will press the mercury into the little vessel. Lower it still further down, till the mercury within it is level with that without; then stop its mouth, take it out and weigh the mercury, and let its weight be w. Subtract this weight from the weight v of the mercury, which would completely fill the whole vessel; then the natural bulk of the air will be $v-w$, whilst its bulk, when of the elasticity e in the rarefied receiver, was the bulk or capacity w of the vessel. Its density therefore, corresponding to this elasticity e, was $\frac{v-w}{w}$. And thus may the relation between density and elasticity in all cases be obtained.

Various experiments made to this purpose.

A great variety of experiments to this purpose have been made, with different degrees of attention, according to the interest which the philosophers had in the result. Those made by M. de Luc, General Roy, Mr. Trembley, and Sir George Shuckburgh, are by far the most accurate; but they are all confined to very moderate rarefactions. The gene-

Boylean Law.

ral result has been, that the elasticity of rarefied air is very nearly proportional to its density. We cannot say with confidence that any regular deviation from this law has been observed, there being as many observations on one side as on the other; but we think that it is not unworthy the attention of philosophers to determine it with precision in the cases of extreme rarefaction, where the irregularities are most remarkable. The great source of error is a certain adhesive sluggishness of the mercury when the impelling forces are very small; and other fluids can hardly be used, because they either smear the inside of the tube and diminish its capacity, or they are converted into vapour, which alters the law of elasticity.

The Boylean law may be assumed.

Let us, upon the whole, assume the Boylean law, viz. that the elasticity of the air is proportional to its density. The law deviates not in any sensible degree from the truth in those cases which are of the greatest practical importance, that is, when the density does not much exceed or fall short of that of ordinary air.

Investigation.

Let us now see what information this gives us with respect to the action of the particles on each other. The investigation is extremely easy. We have seen that a force eight times greater than the pressure of the atmosphere will compress common air into the eighth part of its common bulk, and give it eight times its common density; and in this case we know, that the particles are at half their former distance, and that the number which are now acting on the surface of the piston employed to compress them is quadruple of the number which act on it when it is of the common density. Therefore, when this eightfold compressing force is distributed over a fourfold number of particles, the portion of it which acts on each is double. In like manner, when a compressing force 27 is employed, the air is compressed into $\frac{1}{27}$ of its former bulk, the particles are at $\frac{1}{3}$ of their former distance, and the force is distributed among 9 times the number of particles; the force on each is therefore 3. In short, let $\frac{1}{x}$ be the distance of the particles, the number of them in any given vessel, and therefore the density will be as x^3, and the number pressing by their elasticity on its whole internal surface will be as x^2. Experiment shews, that the compressing force is as x^3, which being distributed over the number as x^2, will give the force on each as x. Now, this force is in immediate equilibrium with the elasticity of the particle immediately contiguous to the compressing surface. This elasticity is therefore as x; and it follows from the nature of perfect fluidity, that the particle adjoining to the compressing surface presses with an equal force on its adjoining particles on every side. Hence we must conclude, that the corpuscular repulsions exerted by the adjoining particles are inversely as their distances from each other, or that the adjoining particles tend to recede from each other with forces inversely proportional to their distances.

Sir Isaac Newton first reasoned properly.

Sir Isaac Newton was the first who reasoned in this manner from the phenomena. Indeed he was the first who had the patience to reflect on the phenomena with any precision. His discoveries in gravitation naturally gave his thoughts this turn, and he very early hinted his suspicions that all the characteristic phenomena of tangible matter were produced by forces which were exerted by the particles at small and insensible distances. And he considers the phenomena of air as affording an excellent example of this investigation, and deduces from them the law which we have now demonstrated; and says, that air consists of particles which avoid the adjoining particles with forces inversely proportional to their distances from each other. From this he deduces (in the second book of his Principles) several beautiful propositions, determining the mechanical constitution of the atmosphere.

Limits.

But it must be noticed that he limits this action to the *adjoining* particles; and this is a remark of immense consequence, though not attended to by the numerous experimenters who adopt the law.

Height of the atmosphere.

It is plain that the particles are supposed to act at a distance, and that this distance is variable, and that the forces diminish as the distances increase. A very ordinary air-pump will rarefy the air 125 times. The distance of the particles is now 5 times greater than before; and yet they still repel each other; for air of this density will still support the mercury in a syphon-gage at the height of 0·24, or $\frac{24}{100}$ of an inch; and a better pump will allow this air to expand twice as much, and still leave it elastic. Thus we see that whatever is the distance of the particles of common air, they can act five times further off. The question comes now to be, Whether, in the state of common air, they really do act five times further than the distance of the adjoining particles? Whilst the particle a acts on the particle b with the force 5, does it also act on the particle c with the force 2·5, on the particle d with the force 1·667, on the particle e with the force 1·25, on the particle f with the force 1, on the particle g with the force 0.833, &c.

Sir Isaac Newton shows in the plainest manner, that this is by no means the case; for if this were the case, he makes it appear that the sensible phenomena of condensation would be totally different from that we observe. The force necessary for a quadruple condensation would be eight times greater, and for a nonuple condensation the force must be 27 times greater. Two spheres filled with condensed air must repel each other, and two spheres containing air that is rarer than the surrounding air must attract each other, &c. &c. All this will appear very clearly, by applying to air the reasoning which Sir Isaac Newton has employed in deducing the sensible law of mutual tendency of two spheres, which consist of particles attracting each other with forces proportional to the square of the distance inversely.

If we could suppose that the particles of air repelled each other with invariable forces at all distances within some small and insensible limit, this would produce a compressibility and elasticity similar to what we observe. For if we consider a row of particles, within this limit, as compressed by an external force applied to the two extremities, the action of the whole row on the extreme points would be proportional to the number of particles, that is, to their distance inversely and to their density: and a number of such parcels, ranged in a straight line, would constitute a row of any sensible magnitude having the same law of compression. But this law of corpuscular force is unlike every thing we observe in nature, and to the last degree improbable.

We must therefore continue the limitation of this mutual repulsion of the particles of air, and be contented for the present with having established it as an experimental fact, that the adjoining particles of air are kept asunder by forces inversely proportional to their distances; or perhaps it is better to abide by the sensible law, that the density of air is proportional to the compressing force. This law is abundantly sufficient for explaining all the subordinate phenomena, and for giving us a complete knowledge of the mechanical constitution of our atmosphere.

The height of the air investigated.

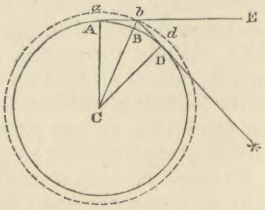
And, in the first place, this view of the compressibility of the air must give us a very different notion of the height of the atmosphere from what we deduced on a former occasion from our experiments. It is found, that when the air is of the temperature 32° of Fahrenheit's thermometer, and the mercury in the barometer stands at 30 inches, it will descend one-tenth of an inch if we take it to a place 87 feet higher. Therefore, if the air were equally dense and heavy throughout, the height of the atmosphere would be 30 × 10 × 87 feet, or 5 miles and 100 yards. But the loose reasoning adduced on that occasion was enough to

Height of the atmosphere.

show us that it must be much higher; because every stratum as we ascend must be successively rarer as it is less compressed by incumbent weight. Not knowing to what degree air expanded when the compression was diminished, we could not tell the successive diminutions of density and consequent augmentation of bulk and height; we could only say, that several atmospheric appearances indicated a much greater height. Clouds have been seen much higher; but the phenomenon of the twilight is the most convincing proof of this. There is no doubt that the visibility of the sky or air is owing to its want of perfect transparency, each particle, whether of matter purely aerial or heterogeneous, reflecting a little light.

Let *b* (fig. 71) be the last particle of illuminated air which can be seen in the horizon by a spectator at A. This must be illuminated by a ray SD *b*, touching the earth's surface at some point D. Now it is a known fact, that the degree of illumination called *twilight* is perceived when the sun is 18° below the horizon of the spectator, that is, when the angle E *b* S or ACD is 18 degrees; therefore *b* C is the secant of 9 degrees (it is less, viz. about 8½ degrees, on account of refraction). We know the earth's radius to be about 3970 miles: hence we conclude *b* B to be about 45 miles; nay, a very sensible illumination is perceptible much farther from the sun's place than this, perhaps twice as far, and the air is sufficiently dense for reflecting a sensible light at the height of nearly 200 miles.

Fig. 71.



Experiment fixes no limit to the air's expansibility.

We have now seen that air is prodigiously expansible. None of our experiments have distinctly shown us any limit. But it does not follow that it is expansible without end; nor is this at all likely. It is much more probable that there is a certain distance of the parts in which they no longer repel each other; and this would be the distance at which they would arrange themselves if they were not heavy. But at the very summit of the atmosphere they will be a very small matter nearer to each other, on account of their gravitation to the earth. Till we know precisely the law of this mutual repulsion, we cannot say what is the height of the atmosphere.

Farther observations.

But if the air be an elastic fluid whose density is always proportionable to the compressing force, we can tell what is its density at any height above the surface of the earth: and we can compare the density so calculated with the density discovered by observation: for this last is measured by the height at which it supports mercury in the barometer. This is the direct measure of the pressure of the external air; and as we know the law of gravitation, we can tell what would be the pressure of air having the calculated density in all its parts.

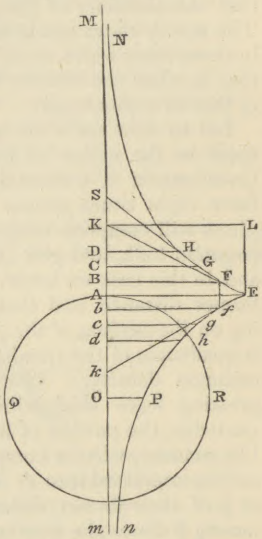
Let us therefore suppose a prismatic or cylindric column of air reaching to the top of the atmosphere. Let this be divided into an indefinite number of strata of very small and equal depths or thickness; and let us, for greater simplicity, suppose at first that a particle of air is of the same weight at all distances from the centre of the earth.

The absolute weight of any one of these strata will on these conditions be proportional to the number of particles or the gravity of air contained in it; and since the depth of each stratum is the same, this quantity of air will evidently be as the density of the stratum. But the density of any stratum is as the compressing force; that is, as the pressure of the strata above it; that is, as their weight; that is, as their quantity of matter: therefore the quantity of air in each stratum is proportional to the quantity of air above it. The quantity in each stratum, however, is the difference between the column incumbent on its bottom and on its top; therefore these differences are proportional to the quantities of which they are the differences. But when there is a series of quantities which are proportional to their own differences, both the quantities and the differences are in continual or geometrical progression: for let *a*, *b*, *c*, be three such quantities that $b : c = a - b : b - c$, then by alternation and composition $a : b = b : c$, therefore the densities of these strata decrease in a geometrical progression; that is, when the elevations above the centre or surface of the earth increase, or their depths under the top of the atmosphere decrease, in an arithmetical progression, the densities decrease in a geometrical progression.

Height of the atmosphere.

Let ARQ (fig. 72), represent the section of the earth by a plane through its centre O, and let *m*OAM be a vertical line, and AE perpendicular to OA will be a horizontal line through A, a point on the earth's surface. Let AE be taken to represent the density of the air at A; and let DH, parallel to AE, be taken to AE as the density at D is to the density at A: it is evident, that if a logistic or logarithmic curve EHN be drawn, having AN for its axis, and passing through the points E and H, the density of the air at any other point C, in this vertical line, will be represented by CG, the ordinate to the curve in that point: for it is the property of this curve, that if portions AB, AC, AD, of its axis to be taken in arithmetical progression, the ordinates AE, BF, CG, DH, will be in the geometrical progression.

Fig. 72.



It is another fundamental property of this curve, that if EK or HS touch the curve in E or H, the subtangent AK or DS is a constant quantity.

And a third fundamental property is, that the infinitely extended area MAEN is equal to the rectangle KAEL of the ordinate and subtangent; and, in like manner, the area MDHN is equal to SD × DH, or to KA × DH; consequently the area lying beyond any ordinate is proportional to that ordinate.

These geometrical properties of this curve are all analogous to the chief circumstances in the constitution of the atmosphere, on the supposition of equal gravity. The area MCGN represents the whole quantity of aereal matter which is above C. For CG is the density at C, and CD is the thickness of the stratum between C and D; and therefore CGHD will be as the quantity of matter or air in it; and in like manner of all the others, and of their sums, or the whole area MCGN; and as each ordinate is proportional to the area above it, so each density, and the quantity of air in each stratum, is proportional to the quantity of air above it; and as the whole area MAEN is equal to the rectangle KAEL, so the whole air of variable density above A might be contained in a column KA, if, instead of being compressed by its own weight, it were without weight, and compressed by an external force equal to the pressure of the air at the surface of the earth. In this case, it would be of the uniform density AE, which it has at the surface of the earth, making what we have repeatedly called the homogeneous atmosphere.

Hence we derive this important circumstance, that the height of the homogeneous atmosphere is the subtangent of that curve, the ordinates of which are as the densities of the air at different heights, on the supposition of equal gravity. This curve may with propriety be called the *atmospherical*

Height of the atmosphere.

logarithmic; and as the different logarithmics are all characterised by their subtangents, it is of importance to determine this one.

It may be done by comparing the densities of mercury and air. For a column of air of uniform density, reaching to the top of the homogeneous atmosphere, is in equilibrio with the mercury in the barometer. Now, it is found, by the best experiments, that when mercury and air are of the temperature of 32° of Fahrenheit's thermometer, and the barometer stands at 30 inches, the mercury is nearly 10440 times denser than air. Therefore the height of the homogeneous atmosphere is 10440 times 30 inches, or 26100 feet, or 8700 yards, or 4350 fathoms, or 5 miles wanting 100 yards.

Or it may be found by observations on the barometer. It is found, that when the mercury and air are of the above temperature, and the barometer on the sea-shore stands at 30 inches, if we carry it to a place 884 feet higher it will fall to 29 inches. Now, in all logarithmic curves having equal ordinates, the portions of the axes intercepted between the corresponding pairs of ordinates are proportional to the subtangents. And the subtangents of the curve belonging to our common tables is 0·4342945, and the difference of the logarithms of 30 and 29, (which is the portion of the axis intercepted between the ordinates 30 and 29), or 0·0147233, is to 0·4342945 as 883 is to 26068 feet, or 8686 yards, or 4343 fathoms, or 5 miles wanting 114 yards. This determination is 14 yards less than the other, and it is uncertain which is the more exact. It is extremely difficult to measure the respective densities of mercury and air; and in measuring the elevation which produces a fall of one inch in the barometer, an error of 1-20th of an inch would produce all the difference. We prefer the last, as depending on fewer circumstances.

But all this investigation proceeds on the supposition of equal gravity, whereas we know that the weight of a particle of air decreases as the square of its distance from the centre of the earth increases. In order, therefore, that a superior stratum may produce an equal pressure at the surface of the earth, it must be denser, because a particle of it gravitates less. The density, therefore, at equal elevations, must be greater than on the supposition of equal gravity, and the law of diminution of density must be different.

$$\begin{aligned} \text{Make } \mathrm{OD} : \mathrm{OA} &= \mathrm{OA} : \mathrm{O}d; \\ \mathrm{OC} : \mathrm{OA} &= \mathrm{OA} : \mathrm{O}c; \\ \mathrm{OB} : \mathrm{OA} &= \mathrm{OA} : \mathrm{O}b; \text{ \&c.}; \end{aligned}$$

so that O*d*, O*c*, O*b*, OA, may be reciprocals to OD, OC, OB, OA; and through the points, A, *b*, *c*, *d*, draw the perpendiculars AE, *bf*, *cg*, *dh*, making them proportional to the densities in A, B, C, D: and let us suppose CD to be exceedingly small, so that the density may be supposed uniform through the whole stratum. Thus we have

$$\begin{aligned} & \mathrm{OD} \times \mathrm{O}d = \mathrm{OA}^2, = \mathrm{OC} \times \mathrm{O}c \\ \text{and } & \mathrm{O}c : \mathrm{O}d = \mathrm{OD} : \mathrm{OC}; \\ \text{and } & \mathrm{O}c : \mathrm{O}c - \mathrm{O}d = \mathrm{OD} : \mathrm{OD} - \mathrm{OC}, \\ \text{or } & \mathrm{O}c : cd = \mathrm{OD} : \mathrm{DC}; \\ \text{and } & cd : \mathrm{CD} = \mathrm{O}c : \mathrm{OD}; \end{aligned}$$

or, because OC and OD are ultimately in the ratio of equality, we have

$$cd : \mathrm{CD} = \mathrm{O}c : \mathrm{OC} = \mathrm{OA}^2 : \mathrm{OC}^2,$$

and $cd = \mathrm{CD} \times \frac{\mathrm{OA}^2}{\mathrm{OC}^2}$, and $cd \times cg = \mathrm{CD} \times cg \times \frac{\mathrm{OA}^2}{\mathrm{OC}^2}$; but $\mathrm{CD} \times cg \times \frac{\mathrm{OA}^2}{\mathrm{OC}^2}$ is as the pressure at C arising from the absolute weight of the stratum CD. For this weight is as the bulk, as the density, and as the gravitation of each particle jointly. Now CD expresses the bulk, *cg* the density, and $\frac{\mathrm{OA}^2}{\mathrm{OC}^2}$, the gravitation of each particle. Therefore, $cd \times cg$ is as the pressure on C arising from the weight of the stratum DC; but $cd \times cg$ is evidently the element of the curvilineal area A*mn*E, formed by the curve E*fg h n* and the ordinates AE, *bf*, *cg*, *ah*, &c. *mn*. Therefore the sum of all the elements, such as *c d h g*, that is, the area *c m n g* below *cg*, will be as the *whole* pressure on C, arising from the gravitation of all the air above it; but, by the nature of air, this whole pressure is as the density which it produces, that is, as *cg*. Therefore the curve E*g n* is of such a nature that the area lying below or beyond any ordinate *cg* is proportional to that ordinate. This is the property of the logarithmic curve, and E *g n* is a logarithmic curve.

Height of the atmosphere.

But farther, this curve is the same with EGN. For let B continually approach to A, and ultimately coincide with it. It is evident that the ultimate ratio of BA to A*b*, and of BF to *bf*, is that of equality; and if EFK, E*fk*, be drawn, they will contain equal angles with the ordinate AE, and will cut off equal subtangents AK, A*k*. The curves EGN, E*gn* are therefore the same, but in opposite positions.

Lastly, if OA, O*b*, O*c*, O*d*, &c. be taken in arithmetical progression decreasing, their reciprocals OA, OB, OC, OD, &c. will be in harmonical progression increasing, as is well known; but, from the nature of the logarithmic curve, when OA, O*b*, O*c*, O*d*, &c. are in arithmetical progression, the ordinates AE, *bf*, *cg*, *dh*, &c. are in geometrical progression. Therefore when OA, OB, OC, OD, &c. are in harmonical progression, the densities of the air at A, B, C, D, &c. are in geometrical progression; and thus may the density of the air at all elevations be discovered. Thus, to find the density of the air at K the top of the homogeneous atmosphere, make $\mathrm{OK} : \mathrm{OA} = \mathrm{OA} : \mathrm{O}d$, and draw the ordinate *dh*, *dh* is the density at K.

The celebrated Dr. Halley was the first who observed the relation between the density of the air and the ordinates of the logarithmic curve, or common logarithms. This he did on the supposition of equal gravity; and his discovery is acknowledged by Sir Isaac Newton in his *Principia*, ii. *prop.* 22, *schol.* Halley's dissertation on the subject is in No. 185 of the *Philosophical Transactions.* Newton, with his usual sagacity, extended the same relation to the true state of the case, where gravity is as the square of the distance inversely; and showed that when the distances from the earth's centre are in harmonic progression, the densities are in geometric progression. He shows, indeed, in general, what progression of the distance, on any supposition of gravity, will produce a geometrical progression of the densities, so as to obtain a set of lines OA, O*b*, O*c*, O*d*, &c. which will be logarithms of the densities.[1]

Probable limit to application of Boyle's law.

From these principles a corollary is deducible, viz., that the air has a finite density at an infinite distance from the centre of the earth, which will be represented by the ordinate OP drawn through the centre. But from this corollary it would follow, that our moon must attract and acquire to itself a portion of this atmosphere, bearing an approximate relation to the gravity at its surface. Astronomy pronounces this highly improbable, and thus sets a practical limit to the law of *compression equal to elasticity*, on which our reasoning is founded.

---

[1] The subject was afterwards treated in a more familiar manner by Cotes in his *Hydrostatic Lectures*, and in his *Harmonia Mensurarum*; by Dr. Brook Taylor, in his *Methodus Increment.*; by Wolf in his *Aerometria*; by Herman in his *Phoronomia*; and by Horsley in the *Philosophical Transactions*, tom. lxiv.

We have thus given an elementary account of the distinguishing properties of air as a heavy and compressible fluid, and of the general phenomena which are immediate consequences of these properties. This we have done in a set of propositions analogous to those which form the doctrines of hydrostatics. It remains to consider it in another point of view, namely, as moveable and inert. The phenomena consequent on these properties are exhibited in the velocities which air acquires by pressure, in the resistance which bodies meet with to their motion through the air, and in the impression which air in motion gives to bodies exposed to its action.

Doctrine of air acted on by equal and parallel gravity.

We shall first consider the motions of which air is susceptible when the equilibrium of pressure, whether arising from its weight or its elasticity, is removed; and, in the next place, we shall consider its action on solid bodies exposed to its current, and the resistance which it makes to their motion through it. In this consideration we shall avoid the extreme of generality, which renders the discussion too abstract and difficult, and adapt our investigation to the circumstances in which compressible fluids, of which air is taken for the representative, are most commonly found. We shall consider air therefore as it is commonly found in accessible situations, as acted on by equal and parallel gravity; and we shall consider it in the same order in which water is treated in a system of hydraulics.

In that science the leading problem is to determine with what velocity the water will move through a given orifice when impelled by some known pressure; and it has been found, that the best form in which this most difficult and intricate proposition can be put, is to determine the velocity of water flowing through this orifice when impelled by its weight alone. Having determined this, we can reduce to this case every question which can be proposed, for in place of the pressure of any piston or other mover, we can always substitute a perpendicular column of water or air whose weight shall be equal to the given pressure.

The velocity with which air rushes into a void.

The first problem, therefore, is to determine with what velocity air will rush into a void when impelled by its weight alone. This is evidently analogous to the hydraulic problem of water flowing out of a vessel. And here we must be contented with referring our readers to the solutions which have been given of that problem, and the demonstration that it flows with the velocity which a heavy body would acquire by falling from a height equal to the depth of the hole under the surface of the water in the vessel. In whatever way we attempt to demonstrate that proposition, every step, nay, every word, of the demonstration applies equally to the air, or to any fluid whatever. Or, if our readers should wish to see the connexion or analogy of the cases, we only desire them to recollect an undoubted maxim in the science of motion, that "when the moving force and the matter to be moved vary in the same proportion, the velocity will be the same." If therefore there be similar vessels of air, water, oil, or any other fluid, all of the height of a homogeneous atmosphere, they will all run through equal and similar holes with the same velocity; for in whatever proportion the quantity of matter moving through the hole be varied by a variation of density, the pressure which forces it out, by acting in circumstances perfectly similar, varies in the same proportion by the same variation of density. We must therefore assume it as the leading proposition, that "air rushes from the atmosphere into a void with the velocity which a heavy body would acquire by falling from the top of a homogeneous atmosphere."

It is known that air is about 840 times lighter than water, and that the pressure of the atmosphere supports water at the height of 33 feet nearly. The height therefore of a homogeneous atmosphere is nearly 33×840, or 27,720 feet. Moreover, to know the velocity acquired by any fall, recollect that a heavy body by falling one foot acquires the velocity of 8 feet per second; and that the velocities acquired by falling through different heights are as the square roots of the heights. Therefore to find the velocity corresponding to any height, expressed in feet per second, multiply the square root of the height by 8. We have therefore in the present instance $V = 8\sqrt{27,720} = 8 \times 166{\cdot}493 = 1332$ feet per second. This therefore is the velocity with which common air will rush into a void; and this may be taken as a standard number in pneumatics, as 16 and 32 are standard numbers in the general science of mechanics, expressing the action of gravity at the surface of the earth.

It is easy to see that greater precision is not necessary in this matter. The height of a homogeneous atmosphere is a variable thing, depending on the temperature of the air. If this reason seems any objection against the use of the number 1332, we may retain $8\sqrt{H}$ in place of it, where H expresses the height of a homogeneous atmosphere of the given temperature. A variation of the barometer makes no change in the velocity, nor in the height of the homogeneous atmosphere, because it is accompanied by a proportional variation in the density of the air. When it is increased $\frac{1}{10}$, for instance, the density is also increased $\frac{1}{10}$; and thus the expelling force and the matter to be moved are changed in the same proportion, and the velocity remains the same. Observe, we do not here consider the velocity which the air acquires after its issuing into the void by its continual expansion. This may be ascertained by the 39th proposition of Newton's *Principia*, book first. Nay, which appears very paradoxical, if a cylinder of air, communicating in this manner with a void, be compressed by a piston loaded with a weight, which presses it down as the air flows out, and thus keeps it of the same density, the velocity of efflux will still be the same, however great the pressure may chance to be; for the first and immediate effect of the load on the piston is to reduce the air in the cylinder to such a density that its elasticity shall exactly balance the load; and because the elasticity of air is proportional to its density, the density of the air will be increased in the same proportion with the load, that is, with the expelling power, for we are neglecting at present the weight of the included air as too inconsiderable to have any sensible effect. Therefore, since the matter to be moved is increased in the same proportion with the pressure, the velocity will be the same as before.

The velocity with which air rushes into a space containing rarer air.

It is equally easy to determine the velocity with which the air of the atmosphere will rush into a space containing rarer air. Whatever may be the density of this air, its elasticity, which follows the proportion of its density, will balance a proportional part of the pressure of the atmosphere; and it is the excess of this last only which is the moving force. The matter to be moved is the same as before. Let D be the natural density of the air, and δ the density of the air contained in the vessel into which it is supposed to run, and let P be the pressure of the atmosphere, and therefore equal to the force which impels it into a void; and let π be the force with which this rarer air would run into a void. We have $D : \delta = P : \pi$, and $\pi = \frac{P\delta}{D}$. Now the moving force in the present instance is $P - \pi$, or $P - \frac{P\delta}{D}$. Lastly, let V be the velocity of air rushing into a void, and v the velocity with which it will rush into this rarefied air.

It is a theorem in the motion of fluids, that the pressures are as the squares of the velocities of efflux.

Therefore $P : P - \frac{P\delta}{D} = V^2 : v^2$. Hence we derive $v^2 = V^2$

Air in motion.

$\times 1-\frac{\delta}{D}$, and $v\times V=\sqrt{1-\frac{\delta}{D}}\Big|$. We do not here consider the resistance which the air of the atmosphere will meet with from the inertia of that in the vessel which it must displace in its motion.

Here we see that there will always be a current into the vessel while δ is less than D.

We also learn the gradual diminution of the velocity as the vessel fills; for δ continually increases, and therefore $1-\frac{\delta}{D}$ continually diminishes.

It remains to determine the time t expressed in seconds, in which the air of the atmosphere will flow into this vessel from its state of vacuity till the air in the vessel has acquired any proposed density δ.

For this purpose let H, expressed in feet, be the height through which a heavy body must fall in order to acquire the velocity V, expressed also in feet per second. This we shall express more briefly in future, by calling it the height producing the velocity V. Let C represent the capacity of the vessel, expressed in cubic feet, and O the area or section of the orifice, expressed in superficial or square feet; and let the natural density of the air be D.

Since the quantity of aerial matter contained in a vessel depends on the capacity of the vessel and the density of the air jointly, we may express the air which would fill this vessel by the symbol CD when the air is in its ordinary state, and by $C\delta$ when it has the density δ. In order to obtain the rate at which it fills, we must take the fluxion of this quantity $C\delta$. This is $C\dot{\delta}$; for C is a constant quantity, and δ is a variable or flowing quantity.

But we also obtain the rate of influx by our knowledge of the velocity, and the area of the orifice, and the density. The velocity is V, or $8\sqrt{H}$, at the first instant; and when the air in the vessel has acquired the density δ, that is, at the end of the time t, the velocity is $8\sqrt{H}\sqrt{1-\frac{\delta}{D}}$, or $8\sqrt{H}\sqrt{\frac{D-\delta}{D}}$, or $8\sqrt{H}\frac{\sqrt{D-\delta}}{\sqrt{D}}$.

The rate of influx therefore (which may be conceived as measured by the little mass of air which will enter during the time $\dot{t}$ with this velocity) will be $\frac{8\sqrt{HOD}\sqrt{D-\delta}\,\dot{t}}{\sqrt{D}}$, or $8\sqrt{HO}\sqrt{D}\sqrt{D-\delta}\,\dot{t}$, multiplying the velocity by the orifice and the density.

Here then we have two values of the rate of influx. By stating them as equal we have a fluxionary equation, from which we may obtain the fluents, that is, the time t in seconds necessary for bringing the air in the vessel to the density δ, or the density δ which will be produced at the end of any time t. We have the equation $8\sqrt{HO}\sqrt{D}\sqrt{D-\delta}\,\dot{t}=C\dot{\delta}$. Hence we derive $\dot{t}=\frac{C}{8\sqrt{HO}\sqrt{D}}\times\frac{\dot{\delta}}{\sqrt{D-\delta}}$.

Of this the fluent is $t=\frac{C}{4\sqrt{HO}\sqrt{D}}\times\sqrt{D-\delta}+A$, in which A is a conditional constant quantity. The condition which determines it is, that t must be nothing when δ is nothing, that is, when $\sqrt{D-\delta}=\sqrt{D}$; for this is evidently the case at the beginning of the motion. Hence it follows, that the constant quantity is $\sqrt{D}$, and the complete fluent, suited to the case, is

$$\frac{C}{4\sqrt{HO}\sqrt{D}}\times\overline{\sqrt{D}-\sqrt{D-\delta}}.$$

Air in motion.

The motion ceases when the air in the vessel has acquired the density of the external air; that is, when $\delta=D$, or when $t=\frac{C}{4\sqrt{HO}\sqrt{D}}\times\sqrt{D},=\frac{C}{4\sqrt{HO}}$. Therefore the time of completely filling the vessel is $\frac{C}{4\sqrt{HO}}$.

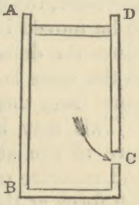
Let us illustrate this by an example in numbers.

Supposing then that air is 840 times lighter than water, and the height of the homogeneous atmosphere 27,720 feet, we have $4\sqrt{H}=666$. Let us further suppose the vessel to contain 8 cubic feet, which is nearly a wine hogshead, and that the hole by which the air of the ordinary density, which we shall make $=1$, enters, is an inch square, or $\frac{1}{144}$ of a square foot. Then the time in seconds of completely filling it will be $\frac{8'}{\frac{1}{144}666}$, or $\frac{1152''}{666}$, or 1.7297″. If the hole is only $\frac{1}{100}$ of a square inch, that is, if its side is $\frac{1}{10}$ of an inch, the time of completely filling the hogshead will be 173″ very nearly, or something less than three minutes.

If we make the experiment with a hole cut in a thin plate, we shall find the time greater nearly in the proportion of 63 to 100, for reasons obvious to all who have studied hydraulics. In like manner we can tell the time necessary for bringing the air in the vessel to $\frac{3}{4}$ths of its ordinary density. The only variable part of our fluent is the coefficient $-\sqrt{D-\delta}$, or $\sqrt{1-\delta}$. Let δ be $=\frac{3}{4}$, then $\sqrt{1-\delta}=\sqrt{\frac{1}{4}}=\frac{1}{2}$, and $\sqrt{1-\delta}=\frac{1}{2}$; and the time is $86\frac{1}{2}''$ very nearly when the hole is $\frac{1}{10}$ of an inch wide.

The velocity of air with the impulse of a weight moving down the vessel.

Fig. 73.



Let us now suppose that the air in the vessel ABCD (fig. 73.) is compressed by a weight acting on the cover AD, which is moveable down the vessel, and is thus expelled into the external air.

The immediate effect of this external pressure is to compress the air and give it another density. The density D of the external air corresponds to its pressure P. Let the additional pressure on the cover of the vessel be p, and the density of the air in the vessel be d. We shall have $P:P+p=D:d$; and therefore $p=P\times\frac{d-D}{D}$. Then, because the pressure which expels the air is the difference between the force which compresses the air in the vessel and the force which compresses the external air, the expelling force is p. And because the quantities of motion are as the forces which similarly produce them, we shall have $P:p\times\frac{d-D}{D}=MV:mv$; where M and m express the quantities of matter expelled, V expresses the velocity with which air rushes into a void, and v expresses the velocity sought. But because the quantities of aerial matter which issue from the same orifice in a moment are as the densities and velocities jointly, we shall have $MV:mv=DVV:dvv=DV^2:dv^2$. Therefore $P:p\frac{d-D}{D}=DV^2:dv$. Hence we deduce

$$V=V\sqrt{\frac{d-D}{d}}\Big|.$$

We may have another expression of the velocity without considering the density. We had $P:P+p=D:d$; therefore $d=\frac{D\times\overline{P+p}}{P}$, and $d-D=\frac{D\times\overline{P+p}}{P}-D,=$

$\frac{D\times\overline{P+p}-DP}{P}$, and $\frac{\dot{d}-D}{d}=\frac{D\times\overline{P+p}-DP}{D\times\overline{P+p}},=\frac{P+p-P}{P+p}=\frac{p}{P+p}$; therefore $v=V\times\sqrt{\frac{p}{P+p}}$, which is a very simple and convenient expression.

Hitherto we have considered the motion of air as produced by its weight only. Let us now consider the effect of its elasticity.

The effect of the air's elasticity considered.

Let ABCD (fig. 73) be a vessel containing air of any density D. This air is in a state of compression; and if the compressing force be removed, it will expand, and its elasticity will diminish along with its density. Its elasticity in any state is measured by the force which keeps it in that state. The force which keeps common air in its ordinary density is the weight of the atmosphere, and is the same with the weight of a column of water 33 feet high. If therefore we suppose that this air, instead of being confined by the top of the vessel, is pressed down by a moveable piston carrying a column of water 33 feet high, its elasticity will balance this pressure as it balances the pressure of the atmosphere; and as it is a fluid, and propagates through every part the pressure exerted on any one part, it will press on any little portion of the vessel by its elasticity in the same manner as when loaded with this column.

The consequence of this reasoning is, that if the small portion of the vessel be removed, and thus a passage be made into a void, the air will begin to flow out with the same velocity with which it would flow when impelled by its weight alone, or with the velocity acquired by falling from the top of a homogeneous atmosphere, or 1332 feet in a second nearly.

But as soon as some air has come out, the density of the remaining air is diminished, and its elasticity is diminished; therefore, the expelling force is diminished. But the matter to be moved is diminished in the very same proportion, because the density and elasticity are found to vary according to the same law; therefore the velocity will continue the same from the beginning to the end of the efflux.

This may be seen in another way. Let P be the pressure of the atmosphere, which being the counter-balance and measure of the initial elasticity, is equal to the expelling force at the first instant. Let D be the initial density, and V the initial velocity. Let d be its density at the end of the time t of efflux, and v the contemporaneous velocity. It is plain that at the end of this time we shall have the expelling force $\pi=\frac{Pd}{D}$; for $D:d=P:\pi\left(=\frac{Pd}{D}\right)$.

These forces are proportional to the quantities of motion which they produce; and the quantities of motion are proportional to the quantities of matter M and m and the velocities V and v jointly: therefore we have $P:\frac{Pd}{D}=MV:mv$. But the quantities of matter which escape through a given orifice are as the densities and velocities jointly; that is, $M:m=DV:dv$: therefore $P:\frac{Pd}{D}=DV^2:dv^2$, and $P\times dv^2=\frac{PdDV^2}{D}=PdV^2$, and $V^2=v^2$, and $V=v$, and the velocity of efflux is constant. Hence follows, what appears very unlikely at first sight, that however much the air in the vessel is condensed, it will always issue into a void with the same velocity.

Quantity of air issuing into a void, and density.

In order to find the quantity of aerial matter which will issue during any time t, and consequently the density of the remaining air at the end of this time, we must get the rate of efflux. In the element of time $\dot{t}$ there issues (by what has been said above) the bulk $8\sqrt{HO}t$ (for the velocity V is constant); and therefore the quantity $8\sqrt{HO}d\dot{t}$. On the other hand, the quantity of air at the beginning was CD, C being the capacity of the vessel; and when the air has acquired the density d, the quantity is Cd; therefore the quantity which has run out in the time $\dot{t}$ must be the fluxion of CD$-$Cd, or $-C\dot{d}$. Therefore we have the equation

$$8\sqrt{HO}d\dot{t}=-C\dot{d}, \text{ and } \dot{t}=\frac{-C\dot{d}}{8\sqrt{HO}d};=\frac{C}{8\sqrt{HO}}\times-\frac{\dot{d}}{d}.$$

The fluent of this is $t=\frac{C}{8\sqrt{HO}}\log.d$. This fluent must be so taken that t may be $=0$ when $d=D$. Therefore the correct fluent will be $t=\frac{C}{8\sqrt{HO}}\log.\frac{D}{d}$, for $\log.\frac{D}{D}=\log.1,=0$. We deduce from this, that it requires an infinite time for the whole air of a vessel to flow out of it into a void. N.B. By log. d, &c. is meant the hyperbolic logarithm of d, &c.

When the vessel emits it into rarer air.

Let us next suppose that the vessel, instead of letting out its air into a void, emits it into air of a less density, which remains constant during the efflux, as we may suppose to be the case when a vessel containing condensed air emits it into the surrounding atmosphere. Let the initial density of the air in the vessel be δ, and that of the atmosphere D. Then it is plain that the expelling force is $P-\frac{PD}{\delta}$, and that after the time t it is $\frac{Pd}{\delta}-\frac{PD}{\delta}$. We have therefore $P-\frac{PD}{\delta}:\frac{Pd}{\delta}-\frac{PD}{\delta}=MV:mv,=\delta V^2:dv^2$. Whence we derive $v=V\sqrt{\frac{\delta\,\overline{d-D}}{d\,\overline{\delta-D}}}$.

From this equation we learn that the motion will be at an end when $d=D$: and if $\delta=D$ there can be no efflux.

Relation between the time and density.

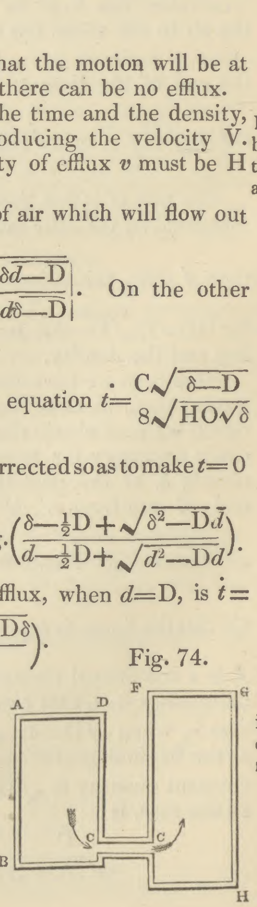
To find the relation between the time and the density, let H, as before, be the height producing the velocity V. The height producing the velocity of efflux v must be $H\times\frac{\delta\overline{d-D}}{d\overline{\delta-D}}$, and the little parcel of air which will flow out in the time t will $=8\sqrt{HO}d\dot{t}\sqrt{\frac{\delta\overline{d-D}}{d\overline{\delta-D}}}$. On the other hand, it is $=-C\dot{d}$.

Hence we deduce the fluxionary equation $\dot{t}=\frac{C\sqrt{\delta-D}}{8\sqrt{HO\sqrt{\delta}}}\times\frac{-\dot{d}}{\sqrt{d^2-Dd}}$. The fluent of this corrected so as to make $t=0$ when $d=\delta$, is $t=\frac{C\sqrt{\delta-D}}{8\sqrt{HO}\sqrt{\delta}}\times\log.\left(\frac{\delta-\frac{1}{2}D+\sqrt{\delta^2-Dd}}{d-\frac{1}{2}D+\sqrt{d^2-Dd}}\right)$. And the time of completing the efflux, when $d=D$, is $\dot{t}=\frac{C\sqrt{\delta-D}}{8\sqrt{HO}\sqrt{\delta}}\times\log.\left(\frac{\delta-\frac{1}{2}D+\sqrt{\delta^2-D\delta}}{\frac{1}{2}D}\right)$.

When issuing from denser into rarer air.

Lastly, let ABCD, CFGH (fig. 74) be two vessels containing airs of different densities, and communicating by the orifice C, there will be a current from the vessel containing the denser air into that containing the rarer; suppose from ABCD into CFGH.

Fig. 74.



Let P be the elastic force of

Air in motion.

the air in ABCD, Q its density, and V its velocity, and D the density of the air in CFGH. And, after the time t, let the density of the air in ABCD be q, its velocity v, and the density of the air in CFGH be δ. The expelling force from ABCD will be $P-\frac{PD}{Q}$ at the first instant, and at the end of the time t it will be $\frac{Pq}{Q}-\frac{P\delta}{Q}$. Therefore we shall have $P-\frac{PD}{Q} : \frac{Pq}{Q}-\frac{P\delta}{Q}=QV^2:qv^2$, which gives $v=V\times\sqrt{\frac{Q(q-\delta)}{q(Q-D)}}$, and the motion will cease when $\delta=q$.

Let A be the capacity of the first vessel, and B that of the second. We have the second equation $AQ+BD=Aq+B\delta$, and therefore $\delta=\frac{A(Q-q)+BD}{qB(Q-D)}$. Substituting this value of δ in the former value of v, we have $v=V\times\sqrt{\frac{Q[B(q-D)-A(Q-q)]}{qB(Q-D)}}$, which gives the relation between the velocity v and the density q.

In order to ascertain the time when the air in ABCD has acquired the density q, it will be convenient to abridge the work by some substitutions. Therefore make $Q(B+A)=M$, $BQD+BQ^2=N$, $BQ-BD=R$ and $\frac{N}{M}=m$. Then, proceeding as before, we obtain the fluxionary equation $8\sqrt{HO}q\frac{\sqrt{Mq-N}}{\sqrt{R}\sqrt{q}}\dot{t}=\overline{A\dot{Q}-q}=-A\dot{q}$, whence $\dot{t}=\frac{A\sqrt{R}}{8\sqrt{HO}\sqrt{M}}\times\frac{q}{\sqrt{q^2-mq}}$ of which the fluent, completed so that $t=0$ when $q=Q$, is $t=\frac{A\sqrt{R}}{8\sqrt{HO}\sqrt{M}}\times\log.\left(\frac{Q-\frac{1}{2}m+\sqrt{(Q^2mQ)}}{q-\frac{1}{2}m+\sqrt{(q^2mq)}}\right)$.

When air is expelled by force.

Some of these questions are of difficult solution, and they are not of frequent use in the more important and usual applications of the doctrines of pneumatics, at least in their present form. The cases of greatest use are when the air is expelled from a vessel by an external force, as when bellows are worked, whether of the ordinary form or consisting of a cylinder fitted with a movement piston. This last case merits a particular consideration; and, fortunately, the investigation is extremely easy.

Let AD (fig. 73) be considered as a piston moving downward with the uniform velocity f, and let the area of the piston be n times the area of the hole of efflux, then the velocity of efflux arising from the motion of the piston be nf. Add this to the velocity V produced by the elasticity of the air in the first question, and the whole velocity will be $V+nf$. It will be the same in the other. The problem is also freed from the consideration of the time of efflux. For this depends now on the velocity of the piston. It is still, however, a very intricate problem to ascertain the relation between the time and the density, even though the piston is moving uniformly; for at the beginning of the motion the air is of common density. As the piston descends, it both expels and compresses the air, and the density of the air in the vessel varies in a very intricate manner, as also its resistance or reaction on the piston. For this reason, a piston which moves uniformly by means of an external force, will never make an uniform blast by successive strokes; it will always be weaker at the beginning of the stroke. The best way for securing an uniform blast is to employ the external force only for lifting up the piston, and then to let the piston descend by its own weight. In this way it will quickly sink down, compressing the air, till its density and corresponding elasticity exactly balance the weight of the piston. After this the piston will descend equably, and the blast will be uniform. These observations and theorems will serve to determine the initial velocity of the air in all important cases of its expulsion. The philosopher will learn the rate of its efflux out of one vessel into another; the chemist will be able to calculate the quantities of the different gases which are employed in the curious experiments of the ingenious but unfortunate Lavoisier on combustion, and will find them extremely different from what he supposed; the engineer will learn how to proportion the motive force of his machine to the quantity of ærial matter which his bellows must supply. But it is not enough, for this purpose, that the air *begin* to issue in the proper quantity; we must see whether it be not affected by the circumstances of its subsequent passage.

Passage of air through pipes, &c.

All the modifications of motion which are observed in water conduits take place also in the passage of air through pipes and holes of all kinds. There is the same diminution of quantity passing through a hole in a thin plate that is observed in water. We know that, abating the small effect of friction, water issues with the velocity acquired by falling from the surface; and yet if we calculate by this velocity and by the area of the orifice, we shall find the quantity of water deficient nearly in the proportion of 63 to 100. This is owing to the water pressing towards the orifice from all sides, which occasions a contraction of the jet. The same thing happens in the efflux of air. Also the motion of water is greatly impeded by all contractions of its passage. These oblige it to accelerate its velocity, and therefore require an increase of pressure to force it through them, and this in proportion to the squares of the velocities. Thus, if a machine working a pump causes it to give a certain number of strokes in a minute, it will deliver a determined quantity of water in that time. Should it happen that the passage of the water is contracted to one half in any part of the machine, a thing which frequently happens at the valves, the water must move through this contraction with twice the velocity that it has in the rest of the passage. This will require four times the force to be exerted on the piston. Nay, if no part of the passage is narrower than the barrel of the pump, but on the contrary a part much wider, and if the conduit be again contracted to the width of the barrel, an additional force must be applied to the piston to drive the water through this passage, which would not have been necessary if the passage had not been widened in any part. It will require a force equal to the weight of a column of water of the height necessary for communicating a velocity, the square of which is equal to the difference of the squares of the velocities of the water in the wide and the narrow part of the conduit.

The same thing takes place in the motion of air, and therefore all contractions and dilatations must be carefully avoided, when we want to preserve the velocity unimpaired.

Air suffers retardation along pipes.

Air also suffers the same retardation in its motion along pipes. By not knowing, or not attending to that, engineers of the first reputation have been prodigiously disappointed in their expectations of the quantity of air which will be delivered by long pipes. Its extreme mobility and lightness hindered them from suspecting that it would suffer any sensible retardation. Dr. Papin, a most ingenious man, proposed this as the most effectual method of transferring the action of a moving power to a great distance. Suppose, for instance, that it was required to raise water out of a mine by a water-machine, and that there was no fall of water nearer than a mile's distance. He employed this water to drive a piston, which should compress the air in a cylinder communicating, by a long pipe, with another cylinder at the mouth of the mine. This second cylinder had a piston in it, whose rod was to give motion to the pumps at the mine. He expected, that as soon as the piston at the water-machine

Air in motion.

had compressed the air sufficiently, it would cause the air in the cylinder at the mine to force up its piston, and thus work the pumps. Dr. Hooke made many objections to the method, when laid before the Royal Society, and it was much debated there. But dynamics was at this time an infant science, and very little understood. Newton had not then taken any part in the business of the society, otherwise the true objections would not have escaped his sagacious mind. Notwithstanding Papin's great reputation as an engineer and mechanic, he could not bring his scheme into use in England; but afterwards, in France and in Germany, where he settled, he got some persons of great fortunes to employ him in this project; and he erected great machines in Auvergne and Westphalia for draining mines. But, so far from being effective machines, they would not even begin to move. He attributed the failure to the quantity of air in the pipe of communication, which must be condensed before it can condense the air in the remote cylinder. This indeed is true, and he should have thought of this earlier. He therefore diminished the size of this pipe, and made his water-machine exhaust instead of condensing, and had no doubt but that the immense velocity with which air rushes into a void would make a rapid and effectual communication of power. But he was equally disappointed here, and the machine at the mine stood still as before.

Nearly a century after this, a very intelligent engineer attempted a much more feasible thing of this kind at an iron-foundery in Wales. He erected a machine at a powerful fall of water, which worked a set of cylinder bellows, the blow-pipe of which was conducted to the distance of a mile and a half, where it was applied to a blast furnace. But notwithstanding every care to make the conducting pipe very air-tight, of great size, and as smooth as possible, it would hardly blow out a candle. The failure was ascribed to the impossibility of making the pipe air-tight. But, what was surprising, above ten minutes elapsed after the action of the pistons in the bellows before the least wind could be perceived at the end of the pipe; whereas the engineer expected an interval of six seconds only.

No very distinct theory can be delivered on this subject; but we may derive considerable assistance in understanding the causes of the obstruction to the motion of water in long pipes, by considering what happens to air. The elasticity of the air, and its great compressibility, have given us the distinctest notions of fluidity in general, shewing us, in a way that can hardly be controverted, that the particles of a fluid are kept at a distance from each other, and from other bodies, by the corpuscular forces.

How fluids are obstructed in moving along canals.

The writers on hydrodynamics have always considered the obstruction to the motion of fluids along canals of any kind, as owing to something like the friction by which the motion of solid bodies on each other is obstructed; but we cannot form to ourselves any distinct notion of resemblance, or even analogy between them. The fact is, however, that a fluid running along a canal has its motion obstructed; and that this obstruction is greatest in the immediate vicinity of the solid canal, and gradually diminishes to the middle of the stream. It appears, therefore, that the parts of fluids can no more move among each other than among solid bodies, without suffering a diminution of their motion. The parts in physical contact with the sides and bottom are retarded by these immoveable bodies. The particles of the next stratum of fluid cannot preserve their initial velocities without overpassing the particles of the first stratum; and it appears from the fact that they are by this means retarded. They retard in the same manner the particles of the third stratum, and so on to the middle stratum or thread of fluid. It appears from the fact, therefore, that this sort of friction is not a consequence of rigidity alone, but that it is equally competent to fluids. Nay, since it is a matter of fact in air, and is even more remarkable there than in any other fluid, as we shall see by the experiments which have been made on the subject; and as our experiments on the compression of air shew us the particles of air ten times nearer to each other in some cases than in others (viz. when we see air a thousand times denser in these cases), and therefore force us to acknowledge that they are not in contact; it is plain that this obstruction has no analogy to friction, which supposes roughness or inequality of surface. No such inequality can be supposed in the surface of an aerial particle; nor would it be of any service in explaining the obstruction, since the particles do not rub on each other, but pass each other at some small and imperceptible distance. We must therefore have recourse to some other mode of explication. We shall apply this to air only in this place; and, since it is proved by the incontrovertible experiments of Canton, Zimmerman, and others, that water, mercury, oil, &c., are also compressible and perfectly elastic, the argument from this principle, which is conclusive in air, must equally explain the similar phenomenon in hydraulics.

Particles of air resist a change from a rectilineal to an undulating motion.

The most highly polished body which we know must be conceived as having an uneven surface when we compare it with the small spaces in which the corpuscular forces are exerted; and a quantity of air moving in a polished pipe may be compared to a quantity of small shot sliding down a channel with undulated sides and bottom. The row of particles immediately contiguous to the sides will therefore have an undulated motion: but this undulation of the contiguous particles of air will not be so great as that of the surface along which they glide; for not only every motion requires force to produce it, but also every change of motion. The particles of air resist this change from a rectilineal to an undulating motion; and, being elastic, that is, repelling each other and other bodies, they keep a little nearer to the surface as they are passing over an eminence, and their path is less incurvated than the surface. The difference between the motion of the particles of air and the particles of a fluid quite unelastic is, in this respect, somewhat like the difference between the motion of a spring-carriage and that of a common carriage. When the common carriage passes along a road not perfectly smooth, the line described by the centre of gravity of the carriage keeps perfectly parallel to that described by the axis of the wheels, rising and falling along with it. Now let a spring body be put on the same wheels and pass along the same road. When the axis rises over an eminence perhaps half an inch, sinks down again into the next hollow, and then rises a second time, and so on, the centre of gravity of the body describes a much straighter line; for upon the rising of the wheels, the body resists the motion, and compresses the springs, and thus remains lower than it would have been had the springs not been interposed. In like manner, it does not sink so low as the axle does when the wheels go into a hollow. And thus the motion of spring-carriages becomes less violently undulated than the road along which they pass. This illustration will, we hope, enable the reader to conceive how the deviation of the particles next to the sides and bottom of the canal from a rectilineal motion is less than that of the canal itself.

It is evident that the same reasoning will prove that the undulation of the next row of particles will be less than that of the first, that the undulation of the third row will be less than that of the second, and so on, as is represented in fig. 75. And thus it appears, that whilst the mass of air has a progressive motion along the pipe or canal, each particle is describing a waving line, of which a line parallel to the direction of the canal is the axis, cutting all these undulations. This axis of each undulated path will be straight or curved as the canal is, and the excursions of the path on each side of its axis will be less and less as the axis of the path is nearer to the axis of the canal.

Fig. 75.

Let us now see what *sensible* effect this will have; for all the motion which we here speak of is imperceptible. It is demonstrated in mechanics, that if a body moving with any velocity be deflected from its rectilineal path by a curved and perfectly smooth channel, to which the rectilineal path is a tangent, it will proceed along this channel with undiminished velocity. Now the path, in the present case, may be considered as perfectly smooth, since the particles do not touch it. It is one of the undulations which we are considering, and we may at present conceive this as without any subordinate inequalities. There should not, therefore, be any diminution of the velocity. Let us grant this of the absolute velocity of the particle; but what we observe is the velocity of the mass, and we judge of it perhaps by the motion of a feather carried along by it. Let us suppose a single atom to be a sensible object, and let us attend to two such particles, one at the side, and the other in the middle: although we cannot perceive the undulations of these particles during their progressive motions, we see the progressive motions themselves. Let us suppose, then, that the middle particle has moved without any undulation whatever, and that it has advanced ten feet. The lateral particle will also have moved ten feet; but this has not been in a straight line. It will not be so far advanced, therefore, in the direction of the canal; it will be left behind, and will appear to us to have been retarded in its motion; and in like manner each thread of particles will apparently be more and more retarded, as it recedes farther from the axis of the canal, or what is usually called the thread of the stream.

The undulatory motion is a real obstruction.

And thus the observed fact is shewn to be a necessary consequence of what we know to be the nature of a compressible or elastic fluid; and that without supposing any diminution in the real velocity of each particle, there will be a diminution of the velocity of the sensible threads of the general stream, and a diminution of the whole quantity of air which passes along it during a given time.

Let us now suppose a parcel of air impelled along a pipe, which is *perfectly* smooth, out of a larger vessel, and issuing from this pipe with a certain velocity. It requires a certain force to change its velocity in the vessel to the greater velocity which it has in the pipe. This is abundantly demonstrated. How long soever we suppose this pipe, there will be no change in the velocity, or in the force to keep it up. But let us suppose that about the middle of this pipe there is a part of it which has suddenly got an undulated surface, however imperceptible. Let us further suppose that the final velocity of the middle thread is the same as before. In this case it is evident that the sum total of the motions of all the particles is greater than before, because the absolute motions of the lateral particles is greater than that of the central particle, which we suppose the same as before. This absolute increase of motion cannot be without an increase of propelling force: the force acting now, therefore, must be greater than the force acting formerly. Therefore, if only the former force had continued to act, the same motion of the central particle could not have been preserved, or the progressive motion of the whole stream must be diminished. And thus we see that this internal insensible undulatory motion becomes a real obstruction to the sensible motion which we observe, and occasions an expense of power.

An additional force necessary for preserving a given progressive motion.

Let us see what will be the consequence of extending this obstructing surface further along the canal. It must evidently be accompanied by an augmentation of the motion produced, if the central velocity be still kept up; for the particles which are now in contact with the sides do not continue to occupy that situation. The middle particles moving faster *forward* get over them, and in their turn come next the side; and as they are really moving equally fast, but not in the direction into which they are now to be forced, force is necessary for changing the direction also; and this is in addition to the force necessary for producing the undulations so minutely treated of. The consequence of this must be, that an additional force will be necessary for preserving a given progressive motion in a longer *obstructing* pipe, and that the motion produced in a pipe of greater length by a given force will be less than in a shorter one, and the efflux will be diminished.

There is another consideration which must have an influence here. Nothing is more irrefragably demonstrated than the necessity of an additional force for producing an efflux through any contraction, even though it should be succeeded by a dilatation of the passage. Now both the inequalities of the sides and the undulations of the motions of each particle are equivalent to a succession of contractions and dilatations; although each of these is next to infinitely small, their number is also next to infinitely great, and therefore the total effect may be sensible.

There are other obstructions, as angular asperities.

We have hitherto supposed that the absolute velocity of the particles was not diminished; this we did, having assumed that the interval of each undulation of the sides was without inequalities. But this was gratuitous; it was also gratuitous that the sides were only undulated. We have no reason for excluding angular asperities. These will produce, and most certainly often produce, real diminutions in the velocity of the contiguous particles; and this must extend to the very axis of the canal, and produce a diminution of the sum total of motion; and in order to preserve the same sensible progressive motion, a greater force must be employed. This is all that can be meant by saying that there is a resistance to the motion of air through long pipes.

There remains another cause of diminution, viz. the want of perfect fluidity, whether arising from the dissemination of solid particles in a real fluid, or from the viscidity of the fluid. We shall not insist on this at present, because it cannot be shown to obtain in air, at least in any case which deserves consideration. It seems of no importance to determine the motion of air hurrying along with it soot or dust. The effect of fogs on a particular modification of the motion of air will be considered under another head. What has been said on this subject is sufficient for our purpose, as explaining the prodigious and unexpected obstruction to the passage of air through long and narrow pipes. We are able to collect an important maxim from it, viz. that all pipes of communication should be made as wide as circumstances will permit; for it is plain that the obstruction depends on the internal surface, and the force to overcome it must be in proportion to the mass of matter which is in motion. The first increases as the diameter of the pipe, and the last as the square. The obstruction must therefore bear a greater proportion to the whole motion in a small pipe than in a large one.

The law of retardation unknown.

It were very desirable to know the law by which the retardation extends from the axis to the sides of the canal, and the proportion which subsists between the lengths of the canal and the forces necessary for overcoming the obstructions when the velocity is given; as also whether the proportion of the obstruction to the whole motion varies with the velocity; but all this is unknown. It does not, however, seem a desperate case in air; we know pretty distinctly the law of action among its particles, viz. that their mutual repulsions are inversely as their distances. This promises to enable us to trace the progress of undulation from the sides of the canal to the axis.

The rate of increase not as the square of the velocities.

We can see that the retardations will not increase so fast as the square of the velocity. Were the fluid incompressible, so that the undulatory path of a particle were invariable, the deflecting forces by which each individual particle is made to describe its undulating path would be precisely such as arise from the path itself and the motion in it; for each particle would be in the situation of a body moving along a fixed path. But in a very compressible fluid, such as air, each particle may be considered as a solitary body, actuated by a projectile and a transverse force, arising from the action of the adjoining particles. Its motion must depend on the adjustment of these forces, in the same manner as the elliptical motion of a planet depends on the adjustment of the force of projection, with a gravitation inversely proportional to the square of the distance from the focus. The transverse force in the present case has its origin in the pressure on the air which is propelling it along the pipe; this, by squeezing the particles together, brings their mutual repulsion into action. Now it is the property of a perfect fluid, that a pressure exerted on any part of it is propagated equally through the whole fluid; therefore the transverse forces which are excited by this pressure are proportional to the pressure itself; and we know that the pressures exerted on the surface of a fluid, so as to expel it through any orifice, or along any canal, are proportional to the squares of the velocities which they produce. Therefore, in every point of the undulatory motion of any particle, the transverse force by which it is deflected into a curve is proportional to the square of its velocity. When this is the case, a body would continue to describe the same curve as before; but, by the very compression, the curvatures are increased, supposing them to remain similar. This would require an increase of the transverse forces; but this is not to be found; therefore the particle will not describe a similar curve, but one which is less incurvated in all its parts; consequently the progressive velocity of the whole, which is the only thing perceivable by us, will not be so much diminished; that is, the obstructions will not increase so fast as they would otherwise do, or as the squares of the velocities.

This reasoning is equally applicable to all fluids, and is abundantly confirmed by experiments in hydraulics, as we shall see when considering the motion of rivers. We have taken this opportunity of delivering our notions on this subject; because, as we have often said, it is in the avowed discrete constitution of air that we see most distinctly the operation of those natural powers which constitute fluidity in general.

Bossut's experiments on pipes and canals.

We would beg leave to mention a form of experiment for discovering the law of retardation with considerable accuracy. Experiments have been made on pipes and canals. M. Bossut, in his *Hydrodynamique*, has given a very beautiful set made on pipes of an inch and two inches in diameter, and 200 feet in length; but although these experiments are very instructive, they do not give us any rule by which we can extend the result to pipes of greater length and different diameters.

Let a smooth cylinder be set upright in a very large vessel or pond, and be moveable round its axis; let it be turned round by means of a wheel and pulley with an uniform motion and determined velocity. It will exert the same force on the contiguous water which would be exerted on it by water turning round it with the same velocity; and as this water would have its motion gradually retarded by the fixed cylinder, so the moving cylinder will gradually communicate motion to the surrounding water. We should observe the water gradually dragged round by it; and the vortex would extend farther and farther from it as the motion is continued, and the velocities of the parts of the vortex will be less and less as we recede from the axis. Now, we apprehend, that when a point of the surface of the cylinder has moved 200 feet, the *motion* of the water at different distances from it will be similar and proportional to, if not precisely the same with, *retardations* of water flowing 200 feet at the same distance from the side of a canal; at any rate, the two are susceptible of an accurate comparison, and the law of retardation may be accurately deduced from observations made on the motions of this vortex.

Wind.

Air in motion is a very familiar object of observation; and it is interesting. In all languages it has got a name; we call it wind; and it is only upon reflection that we consider air as wind in a quiescent state. Many persons hardly know what is meant when air is mentioned; but they cannot refuse that the blast from a bellows is the expulsion of what they contained; and thus they learn that wind is air in motion.

The velocity of win not easily discovered

It is of consequence to know the velocity of wind; but no good and unexceptionable method has been contrived for this purpose. The best seems to be by measuring the space passed over by the shadow of a cloud; but this is extremely fallacious. In the first place, it is certain, that although we suppose that the cloud has the velocity of the air in which it is carried along, this is not an exact measure of the current on the surface of the earth; we may be almost certain that it is greater; for air, like all other fluids, is retarded by the sides and bottom of the channel in which it moves. But, in the next place, it is very gratuitous to suppose, that the velocity of the cloud is the velocity of the stratum of air between the cloud and the earth; we are almost certain that it is not. It was clearly proved by Dr. Hutton of Edinburgh, that clouds are always formed when two parcels of air of different temperatures mix together, each containing a proper quantity of vapour in the state of chemical solution. We know that different strata of air will frequently flow in different directions for a long time. In 1781, whilst a great fleet rendezvoused in Leith Roads during the Dutch war, there was a brisk easterly wind for about five weeks; and, during the last fortnight of this period, there was a brisk westerly current at the height of about three-fourths of a mile. This was distinctly indicated by frequent fleecy clouds at a great distance above a lower stratum of these clouds, which were driving all this time from the eastward. A gentleman who was present at the siege of Quebec in 1759, stated that one day whilst there blew a gale from the west, so hard that the ships at anchor in the river were obliged to strike their topmasts, and it was with the utmost difficulty that some well-manned boats could row against it, carrying some artillery stores to a post above the town, several shells were thrown from the town to destroy the boats; one of the shells burst in the air near the top of its flight, which was about half a mile high. The smoke of this bomb remained in the same spot for above a qaarter of an hour, like a great round ball, and gradually dissipated by diffusion, without removing many yards from its place. When, therefore, two strata of air come from different quarters, and one of them flows over the other, it will be only in the contiguous surfaces that a precipitation of vapour will be made. This will form a thin fleecy cloud; and it will have a velocity and direction which neither belongs to the upper nor to the lower stratum of air which produced it. Should one of these strata come from the east and the other from the west with equal velocities, the cloud formed between them will have no motion at all; should one come from the east, and the other from the north, the cloud will move from the north-east with a greater velocity than either of the strata. So uncertain then is the information given by the clouds either of the velocity or the direction of the wind. A thick smoke from a furnace will give us a much less equivocal measure; and this, combined with the effects of the wind in impelling bodies, or deflecting a loaded plane from the perpendicular, or other effects of this kind, may give us measures of the different currents of wind with a precision sufficient for all practical uses.

The resul of Smeaton's observations.

The celebrated engineer, Mr. John Smeaton, has given, in the 51st volume of the *Philosophical Transactions*, the velocities of wind corresponding to the usual denominations in our language. These are founded on a great number of observations made by himself in the course of his practice in erecting wind-mills. They are contained in the following table:—

Velocity of wind.

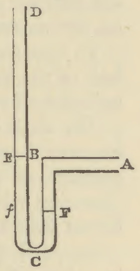
Miles per hour.	Feet per second.	Names.
1	1·47	
2	2·93	Light airs.
3	4·40	
4	5·87	Breeze.
5	7·33	
10	14·67	Brisk gale.
15	22·	
20	29·34	Fresh gale.
25	36·57	
30	44·01	Strong gale.
35	51·34	
40	58·68	Hard gale.
45	66·01	
50	73·35	Storm.
60	88·02	
80	117·36	Hurricane, tearing up trees,
100	146·70	overturning buildings, &c.

Account of Dr. Lind's anemometer.

One of the most ingenious and convenient methods for measuring the velocity of the wind is to employ its pressure in supporting a column of water, in the same way as Mr. Pitot measures the velocity of a current of water. We believe that it was first proposed by Dr. James Lind of Windsor, a gentleman eminent for his great knowledge in all the branches of natural science, and for his ingenuity in every matter of experiment or practical application.

His anemometer consists of a glass tube of the form ABCD (fig. 76), open at both ends, and having the branch AB at right angles to the branch CD. This tube contains a few inches of water or any fluid (the lighter the better); it is held with the part CD upright, and AB horizontal and in the direction of the wind; that is, with the mouth A fronting the wind. The wind acts in the way of pressure on the air in AB, compresses it, and causes it to press on the surface of the liquor; forcing it down to F, whilst it rises to E in the other leg. The velocity of the wind is concluded from the difference E*f* between the heights of the liquor in the legs. As the wind does not generally blow with uniform velocity, the liquor is apt to dance in the tube, and render the observation difficult and uncertain; to remedy this, it is proper to contract very much the communication at C between the two legs. If the tube has half an inch of diameter, and it should not have less, a hole of 1-50th of an inch is large enough; indeed the hole can hardly be too small, nor the tubes too large.

Fig. 76.

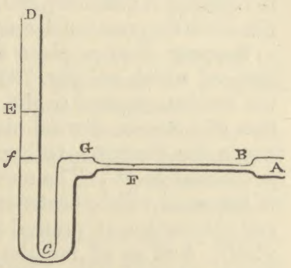


This instrument is extremely ingenious, and will undoubtedly give the proportions of the velocities of different currents with the greatest precision; for in whatever way the pressure of wind is produced by its motion, we are certain that the different pressures are as the squares of the velocities; if, therefore, we can obtain one certain measure of the velocity of the wind, and observe the degree to which the pressure produced by it raises the liquor, we can at all other times observe the pressures and compute the velocities from them, making proper allowances for the temperature and the height of the mercury in the barometer; because the velocity will be in the subduplicate ratio of the density of the air inversely when the pressure is the same.

It is usually concluded, that the velocity of the wind is that which would be acquired by falling from a height which is to E*f* as the weight of water is to that of an equal bulk of air. Thus, supposing air to be 840 times lighter than water, and that E*f* is 9-10ths of an inch, the velocity will be about 63 feet per second, which is that of a very hard gale, approaching to a storm. Hence we see by the bye, that the scale of this instrument is extremely short, and that it would be a great improvement of it to make the leg CD not perpendicular, but very much sloping; or perhaps the following form of the instrument will give it all the perfection of which it is capable. Let the horizontal branch AB (fig. 77) be contracted at B, and continued horizontally for several inches BG of a much smaller bore, and then turned down for two or three inches GC, and then upwards with a wide bore. To use the instrument, hold it with the part DC perpendicular; and (having sheltered the mouth A from the wind) pour in water at D till it advances along GB to the point B, which is made the beginning of the scale; the water in the upright branch standing at *f* in the same horizontal line with BG. Now, turn the mouth A to the wind; the air in AB will be compressed and will force the water along BG to F, and cause it to rise from *f* to E; and the range *f*E will be to the range BF on the scale as the section of the tube BG to that of CD. Thus, if the width of DC be half an inch, and that of BG 1-10th, we shall have 25 inches in the scale for one inch of real pressure E*f*.

Velocity of wind.

Fig. 77.



But it has not been demonstrated in a very satisfactory manner, that the velocity of the wind is that acquired by falling through the height of a column of air whose weight is equal to that of the column of water E*f*. Experiments made with Pitot's tube in currents of water show that several corrections are necessary for conducting the velocity of the current from the elevations in the tube: these corrections may however be made, and safely applied to the present case; and then the instrument will enable us to conclude the velocity of the wind immediately, without any fundamental comparison of the elevation, with a velocity actually determined upon other principles.[1] The chief use which we have for this information is in our employment of wind as an impelling power, by which we can actuate machinery or navigate ships. These are very important applications of pneumatical doctrines, and merit a particular consideration; and this naturally brings us to the last part of our subject, viz. the consideration of the impulse of air on bodies exposed to its action, and the resistance which it opposes to the passage of bodies through it.

This subject important but difficult.

This is a subject of the greatest importance, being the foundation of that art which has done the greatest honour to the ingenuity of man, and the greatest service to human society, by connecting together the most distant inhabitants of this globe, and making a communication of benefits which would otherwise have been impossible; we mean the art of Navigation or Seamanship. Of all the machines which human art has constructed, a ship is not only the greatest and most magnificent, but also the most ingenious and intricate; and the clever seaman possesses a knowledge founded on the most difficult and abstruse doctrines of mechanics. The seaman probably cannot give any account of his own science; and he possesses it rather by a kind of intuition than by any process of reasoning; but the success and efficiency of all the mechanism of this complicated engine, and the propriety of all the manœuvres which the seaman practises, depend on the invariable laws of mechanics; and a thorough knowledge of these would enable an intelligent person not only to understand the machine and the manner of working it, but to improve both.

Unfortunately this is a subject of very great difficulty; and although it has employed the genius of Newton, who has con-

---

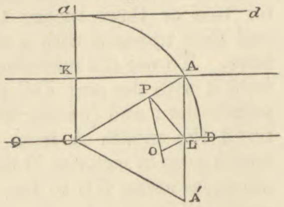
Velocity of wind.

sidered it with great care, and his followers have added more to his labours on this subject than on any other, it still remains in a very imperfect state. A minute discussion of this subject cannot therefore be expected in a work like this; we must content ourselves with such a general statement of the most approved doctrine on the subject as shall enable our readers to conceive it distinctly, and judge with intelligence and confidence of the practical deductions which may be made from it.

Fig. 78.



Suppose then a plane surface, of which aC (fig. 78) is the section, exposed to the action of a stream of wind blowing in the direction QC, perpendicular to aC. The motion of the wind will be obstructed, and the surface aC pressed forward. And as all impulse or pressure is exerted in a direction perpendicular to the surface, and is resisted in the opposite direction, the surface will be impelled in the direction CD, the continuation of QC. And as the mutual actions of bodies depend on their relative motions, the force acting on the surface aC will be the same, if we shall suppose the air at rest, and the surface moving equally swift in the opposite direction. The resistance of the air to the motion of the body will be equal to the impulse of the air in the former case. Thus resistance and impulse are equal and contrary.

Air moving with a double velocity generally impels as the square of that velocity.

If the air be moving twice as fast, its particles will give a double impulse; but in this case a double number of particles will exert their impulse in the same time. The impulse will therefore be fourfold, and in general it will be as the square of the velocity; or if the air and body be both in motion, the impulse and resistance will be proportional to the square of the relative velocity. This is the first proposition on the subject, and it appears very consistent to reason. There will therefore be some analogy between the force of the air's impulse or the resistance of a body, and the weight of a column of air incumbent on the surface; for it is a principle in the action of fluids, that the heights of the columns of fluid are as the squares of the velocities which their pressures produce. Accordingly, the second proposition is, that the absolute impulse of a stream of air, blowing perpendicularly on any surface, is equal to the weight of a column of air which has that surface for its base, and for its height the space through which a body must fall in order to acquire the velocity of the air.

Thirdly, Suppose the surface AC equal to aC no longer to be perpendicular to the stream of air, but inclined to it in the angle ACD, which we shall call the *angle of incidence*; then, by the resolution of forces, it follows, that the action of each particle is diminished in the proportion of radius to the sine of the angle of incidence, or of AC to AL, AL being perpendicular to CD.

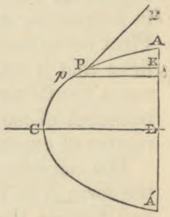
Again: Draw AK parallel to CD. It is plain that no air lying farther from CD than KA is will strike the plane. The quantity of impulse therefore is diminished still farther in the proportion of aC to KC, or of AC to AL. Therefore, on the whole, the absolute impulse is diminished in the proportion of AC^2 to AL^2: hence the proposition, that the impulse and resistance of a given surface are in the proportion of the square of the sine of the angle of incidence.

Fourthly, This impulse is in the direction PL, perpendicular to the impelled surface, and the surface tends to move in this direction: but suppose it moveable only in some other direction PO that we wish to employ this impulse, its action is therefore oblique; and if we wish to know the intensity of the impulse in this direction, it must be diminished still farther in the proportion of radius to the cosine of the angle LPO or sine of CPO. Hence the general proposition: *The effective impulse is as the surface, as the square of the velocity of the wind, as the square of the sine of the angle of incidence, and as the sine of the obliquity jointly*, which we may express by the symbol $R = S \cdot V^{2} \cdot \textit{sin.}^{2}\, I \cdot \textit{sin.}\, O$; and as the impulse depends on the density of the impelling fluid, we may take in every circumstance by the equation $R = S \cdot D \cdot V^{2} \cdot \textit{sin.}^{2}\, I \cdot \textit{sin.}\, O$. If the impulse be estimated in the direction of the stream, the angle of obliquity ACD is the same with the angle of incidence, and the impulse in this direction is as the surface, as the square of the velocity, and as the cube of the angle of incidence jointly.

It evidently follows from these premises, that if ACA′ be a wedge, of which the base AA′ is perpendicular to the wind, and the angle ACA′ bisected by its direction, the direct or perpendicular impulse on the base is to the oblique impulse on the sides as radius to the square of the sine of half the angle ACA′.

The same must be affirmed of a pyramid or cone ACA′, of which the axis is in the direction of the wind.

Fig. 79.



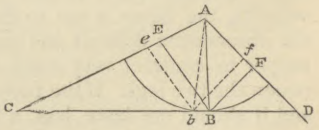
If ACA′ (fig. 79,) represent the section of a solid, produced by the revolution of a curve line APC round the axis CD, which lies in the direction of the wind, the impulse on this body may be compared with the direct impulse on this base, or the resistance to the motion of this body through the air may be compared with the direct resistance of its base, by resolving its surface into elementary planes Pp, which are coincident with a tangent plane PR, and comparing the impulse on P p with the direct impulse on the corresponding part K k of the base.

In this way it follows that the impulse on a sphere is one half of the impulse on its great circle, or on the base of a cylinder of equal diameter.

We shall conclude this sketch of the doctrine with a very important proposition to determine the most advantageous position of a plane surface, when required to move in one direction while it is impelled by the wind blowing in a different direction. Thus,

Inference from this doctrine.

Fig. 80.



Let AB (fig. 80) be the sail of a ship, CA the direction in which the wind blows, and AD the line of the ship's course. It is required to place the yard AC in such a position that the impulse of the wind upon the sail may have the greatest effect possible in impelling the ship along AD.

Let AB, Ab, be two positions of the sail very near the best position, but on opposite sides of it. Draw BE, $b\,e$, perpendicular to CA, and BF, $b\,f$, perpendicular to AD, calling AB radius; it is evident that BE, BF, are the sines of impulse and obliquity, and that the effective impulse is $BE^2 \times BF$, or $b\,e^2 \times b\,f$. This must be a maximum.

Let the points B, b, continually approach and ultimately coincide; the chord b B will ultimately coincide with a straight line CBD touching the circle in B; the triangles CBE, C b e are similar, as also the triangles DBF, D b f: therefore $BE^2 : b\,e^2 = BC^2 : bC^2$, and $BF : b\,f = BD : b\,D$; and $BE^2 \times BF : b\,e^2 \times b\,f = CB^2 \times BD : Cb^2 \times bD$. Therefore when AB is in the best position, so that $BE^2 \times BF$ is greater than $b\,e^2 \times b\,f$, we shall have $CB \times BD$ greater than $Cb^2 \times bD$, or $CB^2 \times BD$ is also a maximum. This we know to be the case when $CB = 2BD$: therefore the sail must be so placed that the tangent of the angle of incidence shall be double of the tangent of the angle of the sail and keel.

In a common windmill the angle CAD is necessarily a right angle; for the sail moves in a circle to which the wind is perpendicular: therefore the best angle of the sail and axle will be 54° 44′ nearly.

Such is the theory of the resistance and impulse of the air. It is extremely simple and of easy application. In all physical theories there are assumptions which depend on other principles, and those on the judgment of the naturalist; so that it is always proper to confront the theory with experiment. There are even circumstances in the present case which have not been attended to in the theory. When a stream of air is obstructed by a solid body, or when a solid body moves along in air, the air is condensed before it and rarefied behind. There is therefore a pressure on the anterior parts arising from this want of equilibrium in the elasticity of the air. This must be superadded to the force arising from the impetus or inertia of the air. We cannot tell with precision what may be the amount of this condensation; it depends on the velocity with which any condensation diffuses itself. Also, if the motion be so rapid that the pressure of the atmosphere cannot make the air immediately occupy the place quitted by the body, it will sustain this pressure on its fore part to be added to the other forces.

The principal experiments on this subject

Experiments on this subjects are by no means numerous; at least such experiments as can be depended on for the foundation of any practical application. The first that have this character are those published by Mr. Robins in 1742, in his *Treatise on Gunnery*. They were repeated with some additions by the Chevalier Borda, and some account of them published in the *Memoirs of the Academy of Sciences in* 1763. In the *Philosophical Transactions of the Royal Society of London*, vol. lxxiii., there are some experiments of the same kind on a larger scale by Mr. Edgeworth. These were all made in the way described in our account of Mr. Robins's improvements in gunnery. Bodies were made to move with determined velocities, and the resistances were measured by weights. In all these experiments the resistances were found very exactly in the proportion of the squares of the velocities; but they were found considerably greater than the weight of the column of air, whose height would produce the velocity in a falling body. Mr. Robins's experiments on a square of 16 inches, describing 25.2 feet per second, indicate the resistance to be to this weight nearly as 4 to 3. Borda's experiments on the same surface state the disproportion still greater.

The resistances are found not to be in the proportion of the surfaces, but increase considerably faster. Surfaces of 9, 16, 36, and 81 inches, moving with one velocity, had resistances in the proportion of 9, $17\frac{1}{2}$, $42\frac{3}{4}$, and $104\frac{3}{4}$.

Now as this deviation from the proportion of the surfaces increases with great regularity, it is most probable that it continues to increase in surfaces of still greater extent; and these are the most generally to be met with in practice in the action of wind on ships and mills.

Borda's experiments on 81 inches show that the impulse of wind moving one foot per second is about $\frac{1}{100}$ of a pound on a square foot. Therefore to find the impulse on a foot corresponding to any velocity, divide the square of the velocity by 500, and we obtain the impulse in pounds. Mr. Rouse of Leicestershire made many experiments, which are mentioned with great approbation by Mr. Smeaton. His great sagacity and experience in the erection of windmills, oblige us to pay a considerable deference to his judgment. These experiments confirm our opinion, that the impulses increase faster than the surfaces. The following table was calculated from Mr. Rouse's observations, and may be considered as pretty near the truth:

Velocity in feet.	Impulse on a foot in pounds.	Velocity in feet.	Impulse on a foot in pounds.
0	0,000	30	2,059
10	0,229	40	3,660
20	0,915	50	5,718
60	8,234	110	27,675
70	11,207	120	32,926
80	14,638	130	38,654
90	18,526	140	44,830
100	22,872	150	51,462

If we multiply the square of the velocity in feet by 16, the product will be the impulse or resistance on a square foot in grains, according to Mr. Rouse's numbers.

The greatest deviation from the theory occurs in the oblique impulses. Mr. Robins compared the resistance of a wedge, whose angle was 90°, with the resistance of its base; and instead of finding it less in the proportion of $\sqrt{2}$ to 1, as determined by the theory, he found it greater in the proportion of 55 to 68 nearly; and when he formed the body into a pyramid, of which the sides had the same surface and the same inclination as the sides of the wedge, the resistance of the base and face were now as 55 to 39 nearly; so that here the same surface with the same inclination had its resistance reduced from 68 to 39 by being put into this form. Similar deviations occur in the experiments of the Chevalier Borda; and it may be collected from both, that the resistances diminish more nearly in the proportion of the sines of incidence than in the proportion of the squares of those sines.

The irregularity in the resistance of curved surfaces is as great as in plane surfaces. In general, the theory gives the oblique impulses on plane surfaces much too small, and the impulses on curved surfaces too great. The resistance of a sphere does not exceed the fourth part of the resistance of its great circle, instead of being its half; but the anomaly is such as to leave hardly any room for calculation. It would be very desirable to have the experiments on this subject repeated in a greater variety of cases, and on larger surfaces, so that the errors of the experiments may be of less consequence. Till this matter is reduced to some rule, the art of working ships must remain very imperfect, as must also the construction of windmills.

The resistance of air in the motion of projectiles.

The case in which we are most interested in the knowledge of the resistance of the air is the motion of bullets and shells. Writers on artillery have long been sensible of the great effect of the air's resistance. It seems to have been this consideration that chiefly engaged Sir Isaac Newton to consider the motion of bodies in a resisting medium. A proposition or two would have sufficed for showing the incompatibility of the planetary motions with the supposition that the celestial spaces were filled with a fluid matter; but he has with great solicitude considered the motion of a body projected on the surface of the earth, and its deviation from the parabolic track assigned by Galileo. He has bestowed more pains on this problem than any other in his whole work; and his investigation has pointed out almost all the improvements which have been made in the application of mathematical knowledge to the study of nature. Nowhere does his sagacity and fertility of resource appear in so strong a light as in the second book of the *Principia*, which is almost wholly occupied by this problem. The celebrated mathematician John Bernoulli engaged in it as the finest opportunity of displaying his superiority. A mistake committed by Newton in his attempt to a solution was matter of triumph to him; and the whole of his performance, though a piece of elegant and elaborate geometry, is greatly hurt by his continually bringing this mistake, which is a mere trifle, into view. The difficulty of the subject is so great, that subsequent mathematicians seem to have kept aloof from it; and it has been entirely overlooked by the many voluminous writers who have treated professedly on military projectiles. They have supposed that the resistance of air was not so great as to render their theories erroneous; but as this will be found discussed under the article Gunnery, nothing more shall be said of it here.

There is another motion of which air and other elastic fluids are susceptible, viz. an internal vibration of their particles, or undulation, by which any extended portion of air is distributed into alternate parcels of condensed and rarefied air, which are continually changing their condition without changing their places. By this change the condensation which is produced in one part of the air is gradually transferred along the mass of air to the greatest distances in all directions. It is of importance to have some distinct conception of this motion. It is found to be by this means that distant bodies produce in us the sensation of sound. Sir Isaac Newton treated this subject with his accustomed ingenuity, and has given us a theory of it in the end of the second book of his *Principia*. This theory has been objected to with respect to the conduct of the argument, and other explanations have been given by the most eminent mathematicians. Though they appear to differ from Newton's, their results are precisely the same; but, on a close examination, they differ no more than John Bernoulli's theorem of centripetal forces differs from Newton's, viz. the one being expressed by geometry and the other by literal analysis. The celebrated Lagrange reduces Newton's investigation to a tautological proposition or identical equation; but Dr M. Young of Trinity College, Dublin, has by a different turn of expression, freed Newton's method from this objection.

This has been used to explain a variety of natural phenomena.

But since Newton published this theory of aerial undulations, and of their propagation along the air, and since the theory has been so corrected and improved as to be received by the most accurate philosophers as a branch of natural philosophy susceptible of rigid demonstration, it has been freely resorted to by many writers on other parts of natural science, who did not profess to be mathematicians, but made use of it for explaining phenomena in their own line on the authority of the mathematicians themselves. Learning from them that this vibration, and the *quaquaversum* propagation of the pulses, were the necessary properties of an elastic fluid, and that the rapidity of this propagation had a certain assignable proportion to the elasticity and density of the fluid, they freely made use of these concessions, and have introduced elastic vibrating fluids into many facts, where others would suspect no such thing, and have attempted to explain by their means many abstruse phenomena of nature. Æthers are everywhere introduced, endued with great elasticity and tenuity. Vibrations and pulses are supposed in this æther, and these are offered as explanations. The doctrines of animal spirits and nervous fluids, and the whole mechanical system of Hartley, by which the operations of the soul are said to be explained, have their foundation in this theory of aerial undulations. If these fancied fluids, and their internal vibrations, really operate in the phenomena ascribed to them, any explanation that can be given of the phenomena from this principle must be nothing else then showing that the legitimate consequences of these undulations are similar to the phenomena; or, if we are no more able to see this last step than in the case of sound, (which we know to be *one* consequence of the aerial undulations, although we cannot tell how), we must be able to point out, as in the case of sound, certain constant relations between the general laws of these undulations and the general laws of the phenomena. It is only in this way that we think ourselves entitled to say that the aerial undulations are causes, though not the only causes, of sound; and it is because there is no such relation, but, on the contrary, a total dissimilarity, to be observed between the laws of elastic undulations and the laws of the propagation of light, that we assert with confidence that ethereal undulations are not the causes of vision.

Explanations of this kind suppose, therefore, in the first place, that the philosopher who proposes them understands precisely the nature of these undulations; in the next place, that he makes his reader sensible of those circumstances of them which are concerned in the effect to be explained; and, in the third place, that he makes the reader understand how this circumstance of the vibrating fluid is connected with the phenomenon, either by showing it to be its mechanical cause, as when the philosopher explains the resounding of a musical chord to a flute or pipe which gave the same tone; or by showing that this circumstance of the undulation always accompanies the phenomenon, as when the philosopher shows that 233 vibrations of air in a second, in whatever manner or by whatever cause they are produced, always are followed by the sensation of the tone C in the middle of the harpsichord.

How elastic differ from unelastic fluids.

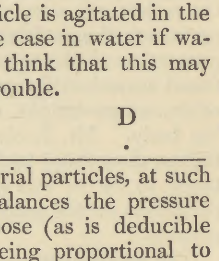
We propose now to give some account of the motion of elastic fluids; and the first thing incumbent on us is to show how these fluids differ from the unelastic in the propagation of any agitation of their parts. When a long tube is filled with water, and any one part of it pushed out of its place, the whole is instantly moved like a solid mass. But this is not the case with air. If a door be suddenly shut, the window at the farther end of a long and close room will rattle; but some time will elapse between the shutting of the door and the motion of the window. If some light dust be lying on a braced drum, and another be violently beat at a little distance from it, an attentive observer will see the dust dance up from the parchment; but this will be at the instant he hears the sound of the stroke on the other drum, and a sensible time after the stroke. Many such familiar facts show that the agitation is gradually communicated along the air; and therefore that when one particle is agitated by any sensible motion, a finite time, however small, must elapse before the adjoining particle is agitated in the same manner. This would not be the case in water if water be perfectly incompressible. We think that this may be made intelligible with very little trouble.

Let A, B, C, D, &c. be a row of aerial particles, at such distances that their elasticity just balances the pressure of the atmosphere; and let us suppose (as is deducible from the observed density of air being proportional to the compressing force) that the elasticity of the particles, by which they keep each other at a distance, is as their distances inversely. Let us farther suppose that the particle A has been carried, with an uniform motion, to *a* by some external force. It is evident that B cannot remain in its present state; for being now nearer to *a* than to C, it is propelled towards C by the excess of the elasticity of A above the natural elasticity of C. Let E be the natural elasticity of the particles, or the force corresponding to the distance BC or BA, and let F be the force which impels B towards C, and let *f* be the force exerted by A when at *a*. We have

$$\mathrm{E} : f = \mathrm{B}a : \mathrm{BC} = \mathrm{B}a,\ \mathrm{BA};$$
$$\text{and } \mathrm{E} : f - \mathrm{E} = \mathrm{B}a : \mathrm{BA} - \mathrm{B}a = \mathrm{B}a : \mathrm{A}a;$$
$$\text{or } \mathrm{E} : \mathrm{F} = \mathrm{B}a : \mathrm{A}a.$$

Now, in fig. 81, let ABC be the line joining three particles, to which draw FG, PH parallel, and IAF, HBG perpendicular. Take IF or HG to represent the elasticity corresponding to the distance AB. Let the particle A be supposed to have been carried with an uniform motion to *a* by some external force, and draw R*a*M perpendicular to RG; and make FI : RM = B*a* : BA. We shall then have FI : PM = B*a* : A*a*; and PM will represent the force

Fig. 81.



with which the particle B is urged towards C. Suppose this construction to be made for every point of the line AB, and that a point M is thus determined for each of them, mathematicians know that all these points M lie in the curve of a hyperbola, of which FG and GH are the asymptotes. It is also known by the elements of mechanics, that since the motion of A along AB is uniform, A*a* or IP may be taken to represent the time of describing A*a*; and that the area IPM represents the whole velocity which B has acquired in its motion towards C when A has come to *a*, the force urging B being always as the portion PM of the ordinate.

Take GX of any length in HG produced, and let GX represent the velocity which the uniform action of the natural elasticity IF could communicate to the particle B during the time that A would uniformly describe AB. Make GX to GY as the rectangle IFGH to the hyperbolic space IFRM, and draw YS cutting MR produced in S, and draw FX cutting MR in T. It is known to the mathematicians that the point S is in a curve line FS*s*, called the *logarithmic curve;* of which the leading property is, that any line RS parallel to GX is to GX as the rectangle IFGH is to the hyperbolic space IFRM, and that FX touches the curve in F.

This being the case, it is plain, that because RT increases in the same proportion with FR, or with the rectangle IFRP, and RS increases in the proportion of the space IFRM, TS increases in the proportion of the space IPM. Therefore TS is proportional to the velocity of B when A has reached *a*, and RT is proportional to the velocity which the uniform action of the natural elasticity would communicate to B in the same time. Then since FT is as the time, and TS is as the velocity, the area FTS will be as the space described by B, urged by the variable force PM; while A, urged by the external force, describes A*a;* and the triangle FRT will represent the space which the uniform action of the natural elasticity would cause B to describe in the same time.

And thus it is plain that these three motions can be compared together: the uniform motion of the agitated particle A, the uniformly accelerated motion which the natural elasticity would communicate to B by its constant action, and the motion produced in B by the agitation of A. But this comparison, requiring the quadrature of the hyperbola and logarithmic curve, would lead us into most intricate and tedious computations. Of these we need only give the result, and make some other comparisons which are palpable.

Let A*a* be supposed indefinitely small in comparison of AB. The space described by A is therefore indefinitely small; but in this case we know that the ratio of the space FRT to the rectangle IFRP is indefinitely small. There is therefore no comparison between the agitation of A by the external force, and the agitation which natural elasticity would produce on a single particle in the same time, the last being incomparably smaller than the first. And this space FRT is incomparably greater than FTS; and therefore the space which B would describe by the uniform action of the natural elasticity is incomparably greater than what it would describe in consequence of the agitation of A.

From this reasoning we see evidently that A must be sensibly moved, or a finite or measurable time must elapse before B acquires a measurable motion. In like manner, B must move during a measurable time before C acquires a measurable motion, &c.; and therefore the agitation of A is communicated to the distant particles in gradual succession.

By a further comparison of these spaces we learn the time in which each succeeding particle acquires the very agitation of A. If the particles B and C only are considered, and the motion of C neglected, it will be found that B has acquired the motion of A a little before it has described one-third of the space described by A; but if the motion of C be considered, the acceleration of B must be increased by the retreat of C, and B must describe a greater space in proportion to that described by A. By computation it appears, that when both B and C have acquired the velocity of A, B has described nearly one-half of A's motion, and C more nearly one-third. Extending this to D, we shall find that D has described still more nearly one-fourth of A's motion. And from the nature of the computation it appears that this approximation goes on rapidly; therefore, supposing it accurate from the very first particle, it follows from the equable motion of A, that each succeeding particle moves through an equal space in acquiring the motion of A.

The conclusion which we must draw from all this is, that when the agitation of A has been fully communicated to a particle at a *sensible* distance, the intervening particles, all moving forward with a common velocity, are equally compressed as to sense, except a very few of the first particles; and that this communication, or this propagation of the original agitation, goes on with an uniform velocity.

These computations need not be attended to by such as do not wish for an accurate knowledge of the precise agitation of each particle. It is enough for such readers to see clearly that time *must* escape between the agitation of A and that of a distant particle; and this is abundantly manifest from the incomparability (excuse the term) of the nascent rectangle IFRP with the nascent triangle FRT, and the incomparability of FRT with FTS.

Newton's demonstration on this subject.

What has now been shown of the communication of any sensible motion A *a* must hold equally with respect to any change of this motion. Therefore if a tremulous motion of a body, such as a spring or bell, should agitate the adjoining particle A by pushing it forward in the direction AB, and then allowing it to come back again in the direction BA, an agitation similar to this will take place in all the particles of the row one after the other. Now if this body vibrate according to the law of motion of a pendulum vibrating in a cycloid, the neighbouring particle of air *will of necessity* vibrate in the same manner; and then Newton's demonstration in the article Acoustics needs no apology. Its only deficiency was, that it *seemed* to prove that this *would be* the way in which every particle would of necessity vibrate; which is not true, for the successive parcels of air will be differently agitated according to the original agitation. Newton only wants to prove the uniform propagation of the agitations, and he selects that form which renders the proof easiest. He proves, in the most unexceptionable manner, that if the particles of a pulse of air are really moving like a cycloidal pendulum, the forces acting on each particle, in consequence of the compression and dilatation of the different parts of the pulse, are precisely such as are necessary for continuing this motion, and therefore no other forces are required. Then since each particle in a certain part of its path, is moving in a certain direction, and with a certain velocity, and urged by a determined force, it *must* move in that very manner. The objection started by John Bernoulli against Newton's demonstration of the elliptical motion of a body urged by a force in the inverse duplicate ratio of the distance from the focus, is precisely the same with the objection against Newton's demonstration of the progress of aerial undulations, and is equally futile.

It must, however, be observed, that Newton's demonstration proceeds on the supposition that the linear agitations of a particle are incomparably smaller than the extent of an undulation. This is not strictly the case in any instance, and in many it is far from being true. In a pretty strong twang of a harpsichord wire, the agitation of a particle may be near the 50th part of the extent of the undulation. This must disturb the regularity of the motion, and cause the agitations in the remote undulations to differ from those in the first pulse. In the explosion of a cannon, the breaking of an exhausted bottle, and many instances which may be given, the agitations are still greater. The commentators on Newton's *Principia*, Le Sueur and Jacquier, have shown, and Euler more clearly, that when the original agitations are very violent, the particles of air will acquire a subordinate vibration compounded with the regular cycloidal vibration, and the progress of the pulses will be somewhat more rapid; but the intricacy of the calculus is so great, that they have not been able to determine with any tolerable precision what the change of velocity will be.

Confirmed by experiments on sounds.

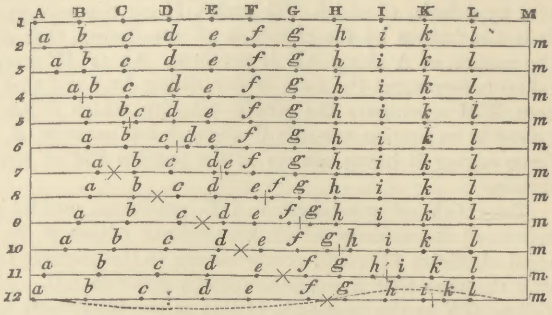
All this, however, is fully confirmed by experiment on sounds. The sound of a cannon at 10 or 20 miles distance does not in the least resemble its sound when near. In this case it is a loud instantaneous crack, to which we can assign no musical pitch. At a distance, it is a grave sound, of which we can tell the note; and it begins softly, swells to its greatest loudness, and then dies away growling. The same may be said of a clap of thunder, which we know to be a loud snap of still less duration. It is highly probable that the appreciable tones which those distant sounds afford are produced by the continuance of these subordinate vibrations which are added together and fortified in the successive pulses, though not perceptible in the first, in a way somewhat resembling the resonance of a musical chord. Newton's explanation gathers evidence therefore from this circumstance. And we must further observe, that all elastic bodies tremble or vibrate almost precisely as a pendulum swinging in a cycloid, unless their vibrations are uncommonly violent; in which case they are quickly reduced to a moderate quantity by the resistance of the air. The only very loud sounds which we can produce in this way are from great bells; and in these the utmost extent of the vibration is very small in comparison with the breadth of the pulse. The velocity of these sounds has not been compared with that of cannon, or perhaps it would be found less, and an objection against Newton's determination removed. He gives 969 feet per second, (experiment 1142.)

The agitation in the successive pulses probably assumes a cycloidal form.

But it is also very probable, that in the propagation through the air, the agitation gradually and rapidly approaches to this regular cycloidal form in the successive pulses, in the same way as we observe that whatever is the form of agitation in the middle of a smooth pond of water, the spreading circles are always of one gentle form without asperities. In like manner, into whatever form we throw a stretched cord by the twang which we give it, it almost immediately makes smooth undulations, keeping itself in the shape of an elongated trochoid. Of this last we can demonstrate the necessity, because the case is simple. In the wave, the investigation is next to impossible; but we see the fact. We may therefore presume it in air. And accordingly we know that any noise, however abrupt and jarring near at hand, is smooth at a distance. Nothing is more rough and harsh than the scream of a heron; but at half a mile's distance it is soft. The ruffle of a drum is also smooth at a distance.

Fig. 82, shows the successive situations of the particles of a row. Each line of the figure shows the same particles marked with the same letters; the first particle *a* being supposed to be removed successively from its quiescent situation and back to it again. The mark × is put on that part of each line where the agitated particles are at their natural distances, and the air is of the natural density. The mark | is put where the air is most of all compressed, and : where it is most of all dilated; the curve line drawn through the lowest line of the figure is intended to represent the density in every point, by drawing ordinates to it from the straight line. The ordinates below the line indicate a rarity, and those above the line a density, greater than common. It appears that when *a* has come back to its natural situation, the part of greatest density is between the particles *i* and *k*, and the greatest rarity between *c* and *d*.

Fig. 82.

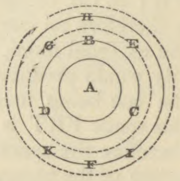


We have only to add, that the velocity of this propagation depends on the elasticity and density of the fluid. If these vary in the same proportion, that is, if the fluid has its elasticity proportional to its density, the velocity will remain the same. If the elasticity or density alone be changed, the velocity of the undulations will change in the direct subduplicate ratio of the elasticity and the inverse subduplicate ratio of the density; or should the elasticity be quadrupled, the quantity of motion produced by it in any given time will be quadrupled. This will be the case if the velocity be doubled; for there would then be double the number of particles doubly agitated. Should the density be quadrupled, the elasticity remaining the same, the quantity of motion must remain the same. This will be the case if the velocity be reduced to one half; for this will propagate half the agitation to half the distance, which will communicate it to twice the number of particles, and the quantity of motion will remain the same. The same may be said of other proportions, and therefore $V=\frac{\sqrt{E}}{\sqrt{D}}$. Therefore a change in the barometer will not affect the velocity of the undulations in air; but they will be accelerated by heat, which diminishes its density, or increases its elasticity. The velocity of the pulses in inflammable air must be at least thrice as great, because its density is but one-tenth of that of air when the elasticity of both are the same.

Further consideration of aerial pulses.

Let us now attend a little to the propagation of aerial pulses as they really happen; for this hypothesis of a single row of particles is nowhere to be observed. Suppose a sphere A, fig. 83, filled with condensed air, and that the vessel which contains it is suddenly annihilated. The air must expand to its natural dimensions, suppose BCD. But it cannot do this without pressing aside the surrounding air. We have seen that in any single row of particles this cannot be at once diffused to a distance, but must produce a condensation in the air adjoining; which will be gradually propagated to a distance. Therefore this sphere BCD of the common density will form round it a shell, bounded by EFG, of condensed air. Suppose that at this instant the inner air BCD becomes solid. The shell of condensed air can expand only outwards. Let it expand till it is of the common density, occupying the shell HIK. This expansion must, in like manner, produce a shell of condensed air without it; and at this instant let HIK become solid. The surrounding shell of condensed air can expand only outward, condensing another shell without it. It is plain that this must go on continually, and the central agitation will be gradually propagated to a distance in all directions. But, in this process, it is not the same numerical particles that go to a distance. Those of the original

Fig. 83.



sphere go no further than BCD, those of the next shall go no further than HIK, &c. Further, the expansion outwards of any particle will be more moderate as the diffusion advances; for the whole motion of each shell cannot exceed the original quantity of motion; and the number of particles in each successive shell increases as the surface, that is, as the square of the distance from the centre; therefore the agitation of the particles will decrease in the same ratio, or will be in the inverse duplicate ratio of the distance from the centre. Each successive shell, therefore, contains the same quantity of motion, and the successive agitations of the particles of any row out from the centre will not be equal to the original agitation, as happens in the solitary row. But this does not affect the velocity of the propagation, because all agitations are propagated equally fast.

We supposed the air A to become solid as soon as it acquired the common density; but this was to facilitate the conception of the diffusion. It does not stop at this bulk; for while it was denser it had a tendency to expand. Therefore each particle has attained this distance with an accelerated motion. It will, therefore, continue this motion like a pendulum that has passed the perpendicular, till it is brought to rest by the air without it; and it is now rarer than common air, and collapses again by the greater elasticity of the air without it. This outward air, therefore, in regaining its natural density, must expand both ways. It expands towards the centre, following the collapsing of the air within it; and it expands outwards, condensing the air beyond it. By expanding inwards, it will again condense the air within it, and this will again expand; a similar motion happens in all the outward shells; and thus there is propagated a succession of condensed and rarefied shells of air, which gradually swell to the greatest distance.

Application of the fact of dropping a pebble into water.

It may be demonstrated, that when the central air has for the second time acquired the natural density, it will be at rest, and be disturbed no more; and that this will happen to all the shells in succession. But the demonstration is much too intricate for this place; and we must be contented with pointing out a fact perfectly analogous. When we drop a small pebble into water, we see it produce a series of circular waves, which go along the surface of smooth water to a great distance, becoming more and more gentle as they recede from the centre; and the middle, where the agitation was first produced, remains perfectly smooth, and this smoothness extends continually; that is, each wave when brought to a level remains at rest. Now these waves are produced and propagated by the depression and elevation made at the centre. The elevation tends to diffuse itself; and the force with which each particle of water is actuated is a force acting directly up and down, and is proportional to the elevation or depression of the particle. This hydrostatical pressure operates precisely in the same way as the condensation and rarefaction of the air; and the mathematical investigation of the propagation of the circular undulations on smooth water is similar in every step to that of the propagation of the spherical waves in still air. For this we appeal to Newton's *Principia*, or to Euler's *Opuscula*, where he gives a very beautiful investigation of the velocity of the aerial pulses; and to some memoirs of Lagrange in the collections of the academies of Berlin and Turin. These two last authors have made the investigation as simple as seems possible, and have freed it from every objection which can be stated against the geometrical one of their greater teacher Newton.

The waves of water are useful in explaining those of air.

Having said this much respecting the similarity between the waves on water and the aerial undulations, we shall have recourse to them, as affording us a very sensible object to represent many affections of the other which it would be extremely difficult to explain. We neither see nor feel the aerial undulations; and they behoved, therefore, to be described very abstractedly and imperfectly. In the watery wave there is no permanent progressive motion of the water from the centre. Throw a small bit of cork on the surface, and it will be observed to popple up and down without the least motion outwards. In like manner, the particles of air are only agitated a very little outwards and inwards, which motion is communicated to the particles beyond them, whilst they themselves come to rest, unless agitated afresh; and this agitation of the particles is inconceivably small. Even the explosion of a cannon at no great distance will but gently agitate a feather, giving it a single impulse outwards, and immediately after another inwards or towards the cannon. When a harpsichord wire is forcibly twanged at a few feet distance, the agitation of the air is next to insensible. It is not, however, nothing; and it differs from that in a watery wave by being *really* outwards and inwards. In consequence of this, when the condensed shell reaches an elastic body, it impels it slightly. If its elasticity be such as to make it acquire the opposite shape at the instant that the next agitation and condensed shell of air touches it, its agitation will be doubled, and a third agitation will increase it, and so on, till it acquire the agitation competent to that of the shell of air which reaches it, and it is thrown into sensible vibration, and gives a sound extremely faint indeed, because the agitation which it acquires is that corresponding to a shell of air considerably removed from the original string. Hence it happens that a musical chord, pipe, or bell, will cause another to resound, whose vibrations are isochronous with its own; or if the vibrations of the one coincides with every second, or third, or fourth, &c. of the other; just as we can put a very heavy pendulum into sensible motion by giving it a gentle puff with the breath at every vibration, or at every second, third, or fourth, &c. A drum struck in the neighbourhood of another drum will agitate it very sensibly; for here the stroke depresses a very considerable surface, and produces an agitation of a considerable mass of air; it will even agitate the surface of stagnant water. The explosion of a cannon will even break a neighbouring window. The shell of condensed air which comes against the glass has a great surface and a great agitation; the best security in this case is to throw up the sash; this admits the condensed air into the room, which acts on the inside of the window, balancing part of the external impulse.

Waves of air and of water in some respects similar

It is demonstrated in every elementary treatise of natural philosophy, that when a wave on water meets any plane obstacle, it is reflected by it from a centre equally removed behind the obstacle; that waves radiating from the focus of a parabola are reflected in waves perpendicular to its axis; that waves radiating from one focus of an ellipse are made to converge to the other focus, &c. All this may be affirmed of the aerial undulations; that when part of a wave gets through a hole in the obstacle, it becomes the centre of a new series of a waves; that waves bend round the extremities of an obstacle; all this happens in the aerial undulations. And lastly, that when the surface of water is thrown into regular undulations by one agitation, another agitation in another place will produce other regular waves, which will cross the former without disturbing them in the smallest degree. The same thing happens in air; and experiments may be made on water which will illustrate in the most perfect manner many other affections of the aerial pulses, which we should otherwise conceive very imperfectly. We would recommend to our curious readers to make some of these experiments in a large vessel of milk. Take a long and narrow plate of lead, which, when set on the bottom of the vessel, will reach above the surface of the milk; bend this plate into a parabola, elliptical, or other curve. Make the undulations by dropping milk on the focus from a small pipe, which will cause the agitations to succeed with rapidity, and then all that we have said will be most distinctly seen, and the experiment will be

Effects of the pressure of the air.

very amusing and instructive, especially to the musical reader.

We shall now proceed to explain a number of natural appearances, depending on the pressure and the elasticity of the air; appearances not sufficiently general, or too complicated for the purposes of argument, whilst we were employed in the investigation of these properties, but too important to be passed over in silence.

The pressure of the air occasions the cohesion of two surfaces, &c.

It is owing to the pressure of the atmosphere that two surfaces which accurately fit each other cohere with such force. This is a fact familiarly known to the glass-grinders, polishers of marble, &c. A large lens or speculum, ground on its tool till it becomes very smooth, requires more than any man's strength to separate it directly from the tool. If the surface is only a square inch, it will require fifteen pounds to separate them perpendicularly, though a very moderate force will make them slide along each other. But this cohesion is not observed unless the surfaces are wetted or smeared with oil or grease; otherwise the air gets between them, and they separate without any trouble. That this cohesion is owing to the atmospheric pressure, is evident from the ease with which the plates may be separated in an exhausted receiver. To the same cause we must ascribe the very strong adhesion of snails, periwinkles, limpets, and other univalve shells, to the rocks. The animal forms the rim of its shell, so as to fit the shape of the rock to which it intends to cling. It then fills its shell, if not already filled by its own body, with water. In this condition it is evident that we must act with a force equal to fifteen pounds for every square inch of touching surface before we can detach it. This may be illustrated by filling a drinking-glass to the brim with water, and having covered it with a piece of thin wet leather, invert it on a table, and then try to pull it straight up; which will require a considerable force. But if we expose a snail adhering to a stone in the exhausted receiver, we shall see it drop off by its own weight. In the same manner do the remora, the polypus, the lamprey, and many other animals, adhere with such firmness. Boys frequently amuse themselves by pulling out large stones from the pavement by means of a circle of stiff wetted leather fastened to a string. It is owing to the same cause that the bivalve shell fishes keep themselves so firmly shut. We think the muscular force of an oyster prodigious, because it requires such force to open it; but if we grind off a bit of the convex shell, so as to make a hole in it, though without hurting the fish in the smallest degree, it opens with great ease, as it does also *in vacuo*.

Other effects of the pressure of the air.

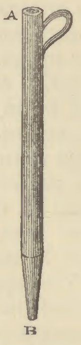
The pressure of the air, operating in this way, contributes much to the cohesion of bodies, where we do not suspect its influence. The tenacity of our mortars and cements would frequently be ineffectual without this assistance. It is owing to the pressure of the atmosphere that a cask will not run by the cock unless a hole be opened in some other part of the cask. If the cask is not quite full, some liquor indeed will run out, but it will stop as soon as the diminished elasticity of the air above the liquor is in equilibrio, together with the liquor, with the atmospheric pressure. In like manner, a teapot must have a small hole in its lid to ensure its pouring out the tea. If indeed the hole in the cask is of large dimensions, it will run without any other, because air will get in at the upper side of the hole while the liquor runs out by the lower part of it. On the same principle depends the performance of an instrument used by the spirit-dealers for taking out a sample of their spirits. It consists of a long tinplate tube AB (fig. 84,) open a-top at A, and ending in a small hole at B. The end B is dipped into the spirits, which rises into the tube; then the thumb is clapt on the mouth A, and the whole is lifted out of the cask. The spirit remains in it till the thumb be taken off; it is then allowed to run into a glass for examination.

Effects of the pressure of the air.

Why frosts instantly occasion a scarcity of water.

It seems principally owing to the pressure of the air that frosts immediately occasion a scantiness of water in our fountains and wells. This is erroneously accounted for, by supposing that the water freezes in the bowels of the earth. But this is a great mistake. The most intense frost of a Siberian winter would not freeze the ground two feet deep; but a very moderate frost will consolidate the whole surface of a country, and make it impervious to the air; especially if the frost has been preceded by rain, which has soaked the surface. When this happens, the water which was filtering through the ground is all arrested and kept suspended in its capillary tubes by the pressure of the air, in the very same manner as the spirits are kept suspended in the instrument just now described by the thumb's shutting the hole A. A thaw melts the superficial ice, and allows the water to run in the same manner as the spirits run when the thumb is removed.

Fig. 84.

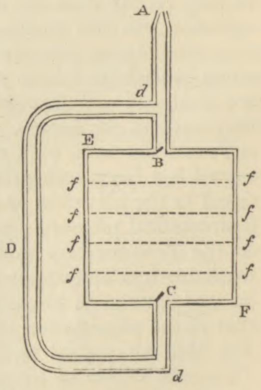


The necessity of common air to animal life.

Common air is necessary for supporting the lives of most animals. If a small animal, such as a mouse or bird, be put under the receiver of an air-pump, and the air be exhausted, the animal will quickly be thrown into convulsions and fall down dead; if the air be immediately readmitted, the animal will sometimes revive, especially if the rarefaction has been briskly made, and has not been very great. We do not know that any breathing animal can bear the air to be reduced to one-fourth of its ordinary density, nor even one-third; nor have we good evidence that an animal will ever recover if the rarefaction is pushed very far, although continued for a very short time.

But the mere presence of the air is by no means sufficient for preserving the life of the animal; for it is found, that an animal shut up in a vessel of air cannot live in it for any length of time. If a man be shut up in a box, containing a wine hogshead of air, he cannot live in it much above an hour, and long before this he will find his breathing very unsatisfactory and uneasy. A gallon of air will support him about a minute. A box EF (fig. 85,) may be made, having a pipe AB inserted into its top, and fitted with a very light valve at B, opening upwards. This pipe sends off a lateral branch *d*D *d*C, which enters the box at the bottom, and is also fitted with a light valve at C opening upwards. If a person breathe through the pipe, keeping his nostrils shut, it is evident that the air which he expires will not enter the box by the hole B, nor return through the pipe CD*d*; and by this contrivance he will gradually employ the whole air of the box. With this apparatus experiments can be made without any risk or inconveniency, and the quantity of air necessary for a given time of easy breathing may be accurately ascertained.

Fig. 85.



How the air of our atmosphere produces this effect is not a question for mechanical philosophy to determine. While a certain amount of atmospheric pressure and elasticity is necessary to balance the mechanical impulse of the blood, and to maintain a sufficient supply of air in the lungs; these play but a subordinate part to the subtle agency more immediately concerned in maintaining the animal functions. Quito in Peru, and the country round Gondar in Abyssinia, are so far elevated above the surface of the ocean, that the pressure and the elasticity of the air are one-third less

Effects of the pressure of the air.

than in the low countries; yet these are populous and healthy places. And, on the other hand, we know, that when an animal has breathed in any quantity of air for a certain time without renewal, it will not only be suffocated, but another animal put into this air will die immediately. And we do not find either the pressure or elasticity of the air remarkably diminished; it is indeed diminished, but by a very small quantity. Restoring the former pressure and elasticity has not the smallest tendency to prevent the death of the animal; for an animal will live no longer under a receiver that has its mouth inverted on water, than in one set upon the pump-plate covered with leather. Now when the receiver is set on water, the pressure of the atmosphere acts completely on the included air, and preserves it in the same state of elasticity.

The nature of air that has been inspired, altered.

In short, it is known that the air which has already served to maintain the animal functions has its chemical and alimentary properties completely changed, and is no longer fit for this purpose. So much of any mass of air as has really been thus employed is changed into what is called *fixed air* by Dr. Black, or *carbonic acid* by the chemists of the school of Lavoisier. Any person may be convinced of this by breathing or blowing through a pipe immersed in lime water. Every expiration will produce white clouds on the water, till all the lime which it contains is precipitated in the form of pure chalk. In this case we know that the lime has combined with the fixed air.

Hales's experiments.

The celebrated Dr. Stephen Hales made many experiments, with a view to clear the air from the noxious vapour which he supposed to be emitted from the lungs. He made use of the apparatus which we have been just now mentioning; and he put several diaphragms *ff*, *ff*, &c. of thin woollen stuff into the box, and moistened them with various liquids. He found nothing so efficacious as a solution of potash. We now understand this perfectly. If the solution is not already saturated with fixed air, it will take it up as fast as it is produced, and this will purify the air: a solution of caustic alkali therefore will have this effect till it is rendered quite mild.

How it comes to be changed.

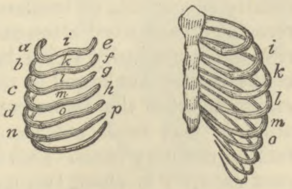
These experiments have been repeated, and varied in many circumstances, in order to ascertain whether this fixed air was really emitted by the lungs, or whether the inspired air was in part changed into fixed air by its combination with some other substance. This is a question which comes properly in our way, and which the doctrines of pneumatics enable us to answer. If the fixed air be emitted in substance from the lungs, it does not appear how a renewal of the air into which it is emitted is necessary, for this does not hinder the subsequent emission; and the bulk of the air would be increased by breathing in it, viz. by the bulk of all the fixed air emitted; but, on the contrary, it is a little diminished. We must therefore adopt the other opinion; and the discoveries in modern chemistry enable us to give a pretty accurate account of the whole process. Fixed air is acknowledged to be a compound, of which one ingredient is found to constitute nearly one-fourth of the whole atmospheric fluid, we mean vital air or the oxygen of Lavoisier. When this is combined with phlogiston, according to the doctrine of Stahl, or with carbon, according to Lavoisier, the result is fixed air or carbonic acid. The change therefore which breathing makes on the air is the solution of this matter by vital air; and the use of air in breathing is the carrying off this noxious principle in the way of solution. When therefore the air is already so far saturated as not to dissolve this substance as fast as it is secreted, or must be secreted in the lungs, the animal suffers the pain of suffocation, or is otherwise mortally affected. Suffocation is not the only consequence; for we can remain for a number of seconds without breathing, and then we begin to feel the true pain of suffocation; but those who have been instantaneously struck down by an inspiration of fixed air, and afterwards recovered to life, complained of no such pain, and seemed to have suffered chiefly by a nervous affection. It is said, but we will not vouch for the truth of it, that a person may safely take a full inspiration of fixed air, if the passages of the nose be shut; and that unless these nerves are stimulated by the fixed air, it is not instantaneously mortal. But these are questions out of our present line of inquiry. They belong to physiology, and are treated of in other places of this work. Our business is to explain in what manner the pressure and elasticity of the air, combined with the structure and mechanism of the body, operate in producing this necessary secretion and removal of the matter discharged from the lungs in the act of breathing.

Effects of the pressure of the air.

It is well ascertained, that the secretion is made from the mass of blood during its passage through the lungs. The blood delivered into the lungs is of a dark blackish colour, and is there changed into a florid red. In the lungs it is exposed to the action of the air in a prodigiously extended surface; for the lungs consist of an inconceivable number of small vessels or bladders, communicating with each other and with the windpipe. These are filled with air in every inspiration. These vessels are everywhere in contact with minute blood-vessels. The blood does not *in toto* come into immediate contact with the air; and it would seem that it is only the thin serous part of it which is acted on by the air at the mouths of the vessels or pores, where it stands by capillary attraction. Dr. Priestley found, that venous blood inclosed in thin bladders and other membranes was rendered florid by keeping the bladders in contact with abundance of pure vital air. We know also, that breath is moist or damp, and must have acquired this moisture in the lungs. It is immaterial whether this secretion of water or lymph, as the anatomists call it, be furnished by mere exudation through simple pores, or by a vascular and organic secretion; in either case, some ingredient of the blood comes in contact with air in the lungs, and there unites with it. This is farther confirmed, by observing, that all breathing animals are warmer than the surrounding medium, and that by every process in which fixed air is formed from vital air, heat is produced. Hence the formation of this gas by the union of atmospheric oxygen with carbon in the blood is generally assigned as the source of animal heat. We touch on these things in a very transitory way in this place, only to prove that, for the support of animal life, there must be a very extensive application of the air to the blood, and that this is made in the lungs.

The question under consideration here is, How is this brought about by the weight and elasticity of the air? The answer is, it is done in two ways; by the action of the muscles of the ribs, and by the action of the diaphragm and other muscles of the abdomen. The thorax or chest is a great cavity, completely filled by the lungs. The sides of this cavity are formed by the ribs. These are crooked or arched, and each is moveable round its two ends, one of them being inserted into the vertebra of the back, and the other into the sternum or breast-bone. The rib turns in a manner resembling the handle of a drawer. The inspection of fig. 86 will illustrate this matter a little. Suppose the curves *a c e*, *b k f*, *c l g*, &c. to represent the ribs moveable round the extremities. Each succeeding rib is more bent than the one above it, and this curvature is both in the vertical and horizontal direction. Suppose each so broad as to project a little over its inferior like the tiles of a roof. It is evident, that if we take the lower one by its middle, and draw it out a little, moving it round the line *np*, it will bring out the next *dmh* along with it. Also, because the dis-

Fig. 86.



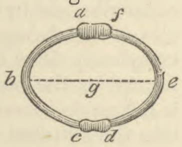
Effects of the pressure of the air.

Effects of the pressure of the air.

tance of the middle point o from the axis of motion np is greater than the distance of m from the axis dh, and because o will therefore describe a portion of a larger circle than m does, the rib nop will slide up a little under the rib dmh, or the rib dmh will overlap nop a little more than before; the distance om will therefore be diminished. The same must happen to all the superior ribs; but the change of distance will be less and less as we go upwards. Now, instead of this great breadth of the ribs overlapping each other, suppose each inferior rib connected with the one above it by threads or fibres susceptible of contraction at the will of man. The articulations e, a, of the first or upper rib with the spine and sternum are so broad and firm, that this rib can have little or no motion round the line ae; this rib therefore is as a fixture for the ends of all the contracting fibres: therefore, whenever the fibres which connect the second rib with the first rib contract, the second must rise a little, and also go outward, and will carry the lower ribs along with it; the third rib will still rise farther by the contraction of the muscles which connect it with the second, and so on; and thus the whole ribs are raised and thrown outward (and a little forward, because the articulation of each with the spine is considerably higher than that with the sternum), and the capacity of the thorax is enlarged by the contraction of its muscular covering. The direction of the muscular fibres is very oblique to the direction of the circular motion which it produces; from which circumstance it follows, that a very minute contraction of the muscles produces all the motion which is necessary. This indeed is not great; the whole motion of the lowest ribs is less than an inch in the most violent inspiration, and the whole contraction of the muscles of the twelve ribs does not exceed the eighth part of an inch, even supposing the intercostal muscles at right angles to the ribs; and being oblique, the contraction is still less. It would seem, that the intensity of the contractive power of a muscular fibre is easily obtained, but that the space through which it can be exerted is very limited; for in most cases nature places the muscles in situations of great mechanical disadvantage in this respect, in order to procure other conveniences.

But this is not the whole effect of the contraction of the intercostal muscles; since the compound action of the two sets of muscles, which cross each other from rib to rib like the letter X, is nearly at right angles to the rib, but is oblique to its plane, it tends to push the ribs closer on their articulations, and thus to press out the two pillars on which they are articulated. Thus, supposing af (fig. 87) to represent the section of one of the vertebræ of the spine, and $c\,d$ a section of the sternum, and $a\,b\,c$, $f\,e\,d$, two opposite ribs, with a lax thread $b\,e$ connecting them. If this thread be pulled upwards by the middle g till it is tight, it will tend to pull the points b and e nearer to each other, and to press the vertebra af and the sternum $c\,d$ outwards. The spine being the chief pillar of the body, may be considered as immoveable in the present instance. The sternum is sufficiently susceptible of motion for the present purpose. It remains almost fixed a-top at its articulation with the first rib, but it gradually yields below; and thus the capacity of the thorax is enlarged in this direction also. The whole enlargement of the diameters of the thorax during inspiration is very small, not exceeding the fiftieth part of an inch in ordinary cases. This is easily calculated. Its quiescent capacity is about two cubic feet, and we never draw in more than fifteen inches. Two spheres, one of which holds two cubic feet and the other two feet and fifteen inches, will not differ in diameter above the fiftieth part of an inch.

Fig. 87.



The other method of enlarging the capacity of the thorax is very different. It is separated from the abdomen by a strong muscular partition called the diaphragm, which is attached to firm parts all around. In its quiescent or relaxed state it is considerably convex upwards, that is, towards the thorax, rising up into its cavity like the bottom of an ordinary quart bottle, only not so regular in its shape. Many of its fibres tend from its middle to the circumference, where they are inserted into firm parts of the body. Now suppose these fibres to contract. This must draw down its middle, or make it flatter than before, and thus enlarge the capacity of the thorax.

Physiologists are not well agreed as to the share which each of these actions has in the operation of enlarging the thorax. Many refuse all share of it to the intercostal muscles, and say that it is performed by the diaphragm alone. But the fact is, that the ribs are really observed to rise even while the person is asleep; and this cannot possibly be produced by the diaphragm, as these anatomists assert. Such an opinion shows either ignorance or neglect of the laws of pneumatics. If the capacity of the thorax were enlarged only by drawing down the diaphragm, the pressure of the air would compress the ribs, and make them descend. And the simple laws of mechanics make it as evident as any proposition in geometry, that the contraction of the intercostal muscles must produce an elevation of the ribs and enlargement of the thorax; and it is one of the most beautiful contrivances of nature. It depends much on the will of the animal what share each of these actions shall have. In general, the greatest part is done by the diaphragm; and any person can breathe in such a manner that his rib shall remain motionless; and, on the contrary, he can breathe almost entirely by raising his chest. In the first method of breathing, the belly rises during inspiration, because the contraction of the diaphragm compresses the upper part of the bowels, and therefore squeezes them outwards; so that an ignorant person would be apt to think that the breathing was performed by the belly, and that the belly is inflated with the air. The strait lacing of the women impedes the motion of the ribs, and changes the natural habit of breathing, or brings on an unnatural habit. When the mind is depressed, it is observed that the breathing is more performed by the muscles of the thorax; and a deep sigh is always made in this way.

These observations on the manner in which the capacity of the chest can be enlarged were necessary, before we can acquire a just notion of the way in which the mechanical properties of air operate in applying it to the mass of blood during its passage through the lungs. Suppose the thorax quite empty, and communicating with the external air by means of the trachea or windpipe, it would then resemble a pair of bellows. Raising the boards corresponds to the raising of the ribs; and we might imitate the action of the diaphragm by forcibly pulling outwards the folded leather which unites them. Thus their capacity is enlarged, and the air rushes in at the nozzle by its weight in the same manner as water would do. The thorax differs from bellows only in this respect, that it is filled by the lungs, which is a vast collection of little bladders, like the holes in a piece of fermented bread, all communicating with the trachea, and many of them with each other. When the chest is enlarged, the air rushes into them all in the same manner as into the single cavity of an empty thorax. It cannot be said with propriety that they are inflated; all that is done is the allowing the air to come in. At the same time, as their membranous covering must have some thickness, however small, and some elasticity, it is not unlikely that, when compressed by expiration, they tend a little to recover their former shape, and thus aid the voluntary action of the muscles. It is in this manner that a small bladder of caoutchouc swells again after compression, and fills itself with air or water. But this cannot happen except in the most minute vesicles; those of sensible bulk have not elasticity enough for this purpose. The lungs of birds, however, have some very large bladders, which have a very considerable elasticity, and recover their shape and size with great force after compression, and thus fill themselves with air. The respiration of these animals is considerably different from that of land animals, and their muscles act chiefly in expiration. This will be explained by and by as a curious variety in the pneumatic instrument.

Air taken in, not by our own action, but by external pressure.

This account of the manner in which the lungs are filled with air does not seem agreeable to the notions we entertain of it. We seem to suck in the air; but although it be true that we act, and exert force, in order to get air into our lungs, it is not by our action, but by external pressure, that it does come in. If we apply our mouth to the top of a bottle filled with water, we find that no draught, as we call it, of our chest will suck in any of the water, but if we suck in the very same manner at the end of a pipe immersed in water, it follows immediately. Our interest in the thing makes us connect in imagination our own action with the effect, without thinking on the many steps which may intervene in the train of natural operations; and we consider the action as the immediate cause of the reception of the air into the lungs. It is as if we opened the door, and took in by the hand a person who was really pushed in by the crowd without. If an incision be made into the side of the thorax, so that the air can get in by that way, when the animal acts in the usual manner, the air will really come in by this hole, and fill the space between the lungs and the thorax; but no air is sucked into the lungs by this process, and the animal is as completely suffocated as if the windpipe were shut up. And, on the other hand, if a hole be made into the lungs without communicating with the thorax, the animal will breathe through this hole, though the windpipe be stopped. This is successfully performed in cases of patients whose trachea is shut up by accident or by inflammation; only it is necessary that this perforation be made into a part of the lungs where it may meet with some of the great pulmonary passages; for if made into some remote part of a lobe, the air cannot find its way into the rest of the lungs through such narrow passages, obstructed too by blood, &c.

Nature of expiration.

We have now explained, on pneumatical principles, the process of inspiration. The expiration is chiefly performed by the natural tone of the parts. In the act of inspiration the ribs were raised and drawn outwards in opposition to the elasticity of the solids themselves; for although the ribs are articulated at their extremities, the articulations are by no means such as to give a free and easy motion like the joints of the limbs. This is particularly the case in the articulations with the sternum, which are by no means fitted for motion. It would seem that the motion really produced here is chiefly by the yielding of the cartilaginous parts and the bending of the rib; when therefore the muscles which produced this effect are allowed to relax, the ribs again collapse. Perhaps this is assisted a little by the action of the long muscles which come down across the ribs without being inserted into them. These may draw them together a little, as we compress a loose bundle by a string. In like manner, when the diaphragm was drawn down, it compressed the abdomen in opposition to the elasticity of all the viscera contained in it, and to the elasticity and tone of integuments and muscles which surround it. When therefore the diaphragm is relaxed, these parts push it up again into its natural situation, and in doing this expel the air from the lungs.

It requires no effort.

If this be a just account of the matter, expiration should be performed without any effort. This accordingly is the case. We feel that, after having made an ordinary easy inspiration, it requires the continuance of the effort to keep the thorax in this enlarged state, and that all that is necessary for expiration is to cease to act. No person feels any difficulty in emptying the lungs; but weak people often feel a difficulty of inspiration, and compare it to the feeling of a weight on their breast; and expiration is the last motion of the thorax in a dying person. But nature has also given us a mechanism by which we can expire, namely, the abdominal muscles; and when we have finished an ordinary and easy expiration, we can still expel a considerable bulk of air—nearly half the contents of the lungs—by contracting the abdominal muscles. These, by compressing the body, force up its moveable contents against the diaphragm, and cause it to rise further into the thorax, acting in the same manner as when we expel the fæces *per anum.* When a person breathes out as much air as he can in this manner, he may observe that his ribs do not collapse during the whole operation.

A certain quantity of air necessary to keep the lungs of a natural size.

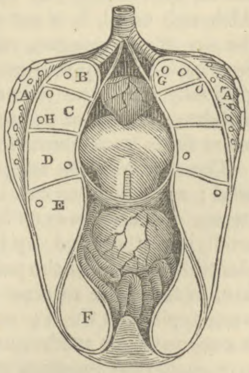
There seems then to be a certain natural unconstrained state of the vesicles of the lungs, and a certain quantity of air necessary for keeping them of this size. It is probable that this state of the lungs gives the freest motion to the blood. Were they more compressed, the blood-vessels would be compressed by the adjoining vesicles; were they more lax, the vessels would be more crooked, and by this means obstructed. The frequent inspirations gradually change this air by mixing fresh air with it, and at every expiration carrying off some of it. In catarrhs and inflammations, especially when attended with suppuration, the small passages into the remote vessels are obstructed, and thus the renewal of air in them will be prevented. The painful feeling which this occasions, causes us to expel the air with violence, shutting the windpipe, till we have exerted strongly with the abdominal muscles, and made a strong compression on the lower part of the thorax. We then open the passage suddenly, and expel the air and obstructing matter by violent coughing.

Process of breathing in birds.

We have said, that birds exhibit a curious variety in the process of breathing. The muscles of their wings being so very great, required a very extensive insertion, and this is one use of the great breast bone. Another use of it is, to form a firm partition to hinder the action of these muscles from compressing the thorax in the act of flying; therefore the form of their chest does not admit of alternate enlargement and contraction to that degree as in land animals. Moreover, the muscles of their abdomen are also very small; and it would seem that they are not sufficient for producing the compression on the bowels which is necessary for carrying on the process of concoction and digestion. Instead of aiding the lungs, they receive help from them.

In the ostrich, the lungs consist of a fleshy part A, A, (fig. 88) composed of vesicles like those of land animals, and, like theirs, serving to expose the blood to the action of the air. Besides these, they have on each side, four large bags, B, C, D, E, each of which has an orifice G, communicating with the trachea; but the second, C, has an orifice, H, by which it communicates with another bag F, situated below the rest in the abdomen. Now, when the lungs are compressed by the action of the diaphragm, the air in C is partly expelled by the trachea through the orifice G, and partly driven through the orifice H into the bag F, which is then allowed to receive it, because the same action which compresses the lungs enlarges the abdomen. When the thorax is enlarged, the bag C is partly supplied with fresh air through the trachea, and partly from the bag F. As the lungs of other animals resemble a common bellows, the

Fig. 88.



Effects of the pressure of the air.

lungs of birds resemble the smith's bellows with a partition; and anatomists have discovered passages from this part of the lungs into their hollow bones and quills. We do not know all the uses of this contrivance; and only can observe, that this alternate action must assist the muscles of the abdomen in promoting the motion of the food along the alimentary canal, &c. We can distinctly observe in birds that their belly dilates when the chest collapses, and *vice versa*, contrary to what we see in the land animals. Another use of this double passage may be to produce a circulation of air in the lungs, by which a compensation is made for the smaller surface of action on the blood; for the number of small vesicles, of equal capacity with these large bags, give a much more extensive surface.

If we try to raise mercury in a pipe by the action of the chest alone, we cannot raise it above two or three inches; and the attempt is both painful and hazardous. It is painful chiefly in the breast, and it provokes coughing. Probably the fluids ooze through the pores of the vesicles by the pressure of the surrounding parts. On the other hand, we can by expiration support mercury about five or six inches high; but this also is very painful, and apt to produce extravasation of blood. This seems to be done entirely by the abdominal muscles.

The operation of sucking.

The operation properly termed *sucking*, is totally different from breathing, and resembles exceedingly the action of a common pump. Suppose a pipe held in the mouth, and its lower end immersed in water. We fill the mouth with the tongue, bringing it forward, and applying it closely to the teeth and to the palate; we then draw it back, or bend it downwards from the palate behind, thus leaving a void. The pressure of the air on the cheeks immediately depresses them, and applies them close to the gums and teeth; and its pressure on the water in the vessel causes it to rise through the pipe into the empty part of the mouth, which it quickly fills. We then push forward the tip of the tongue, below the water, to the teeth, and apply it to them all round, the water being above the tongue, which is kept much depressed. We then apply the tongue to the palate, beginning at the tip, and gradually going backward in this application. By this means the water is gradually forced backward by an operation similar to that of the gullet in swallowing. This is done by contracting the gullet above, and relaxing it below, just as we would empty a gut of its contents, by drawing our closed hand along it. By this operation the mouth is again completely occupied by the tongue, and we are ready for repeating the operation. Thus the mouth and tongue resemble the barrel and piston of a pump; and the application of the tip of the tongue to the teeth, performs the office of the valve at the bottom of the barrel, preventing the return of the water into the pipe. Although usual, it is not absolutely necessary, to withdraw the tip of the tongue, making a void before the tongue. Sucking may be performed by merely separating the tongue gradually from the palate, beginning at the root. If we withdraw the tip of the tongue a very minute quantity, the water flows back above the tongue.

The action of the tongue in this operation is very powerful; some persons can raise mercury 25 inches; but this strong exertion is very fatiguing, and the soft parts are prodigiously swelled by it. It causes the blood to ooze plentifully through the pores of the tongue, fauces, and palate, in the same manner as if a cupping-glass and syringe were applied to them; and, when the inside of the mouth is excoriated or tender, as is frequent with infants, even a very moderate exertion of this kind is accompanied with extravasation of blood. When children suck the nurse's breast, the milk follows their exertion by the pressure of the air on the breast; and a weak child, or one that withholds its exertions on account of pain from the above mentioned cause, may be assisted by a gentle pressure of the hand on the breast. The infant pupil of nature, without any knowledge of pneumatics, frequently helps itself by pressing its face to the yielding breast.

Effects of the pressure of the air.

In the whole of this operation the breathing is performed through the nostrils; and it is a prodigious distress to an infant when this passage is obstructed by mucus. We beg to be forgiven for observing by the way, that this obstruction may be almost certainly removed for a little while, by rubbing the child's nose with any liquid of quick evaporation, or even with water.

Of drinking.

The operation in drinking is not very different from that in sucking. We have indeed little occasion here to suck, but we must do it a little. Dogs, and some other animals, cannot drink, but only lap the water into their mouths with their tongues, and then swallow it. The gallinaceous birds seem to drink very imperfectly. They seem merely to dip their head into the water, up to the eyes, till their mouth is filled with water, and then holding up the head, it gets into the gullet by its weight, and is then swallowed. The elephant drinks in a very complicated manner. He dips his trunk into the water, and fills it by making a void in his mouth. This he does in the contrary way to man. After having depressed his tongue, he begins the application of it to the palate at the root, and by extending the application forward, he expels the air by the mouth which came into it from the trunk. The process here is not very unlike that of the condensing syringe without a piston valve, in which the external air, corresponding to the air in the trunk, enters by the hole in the side, and is expelled through the hole in the end of the barrel; by this operation the trunk is filled with water; then he lifts his trunk out of the water, and bringing it to his mouth, pours the contents into it, and swallows it. On considering this operation, it appears that, by the same process by which the air of the trunk is taken into the mouth, the water could also be taken in, to be afterwards swallowed; but we do not find, upon inquiry, that this is done by the elephant; we have always observed him to drink in the manner now described. In either way it is a double operation, and cannot be carried on any way but by alternately sucking and swallowing, and while one operation is going on, the other is interrupted; whereas man can do both at the same time. Nature seems to delight in exhibiting to rational observers her inexhaustible variety of resource; for many insects which drink with a trunk, drink without interruption; yet we do not call in question the truth of the aphorism, *Natura maxime simplex et semper sibi consona*, nor doubt but that, if the *whole* of her purpose were seen, we should find that her process is the simplest possible; for Nature, or Nature's God, is wise above our wisest thoughts, and simplicity is certainly the choice of wisdom; but, alas! it is generally but a small and the most obvious part of her purpose that we can observe or appreciate. We seldom see this simplicity of nature stated to us, except by some system-maker, who has found a principle which somehow tallies with a considerable variety of phenomena, and then cries out, *Frustra sit per plura quod fieri potest per pauciora*.

Mode of keeping up a continued blast with a blow-pipe.

There is an operation similar to that of the elephant, which many find a great difficulty in acquiring; namely, keeping up a continued blast with a blow-pipe. We would desire our chemical reader to attend minutely to the gradual action of his tongue in sucking, and he will find it such as we have described. Let him attend particularly to the way in which the tip of the tongue performs the office of a valve, preventing the turn of the water into the pipe; and the same position of the tongue would hinder air from coming into the mouth. Next let him observe, that in swallowing what water he has now got lodged above his tongue, he continues the tip of the tongue applied to the teeth; now let him shut his mouth, keeping his lips firm together, the tip of the tongue at the

Effects of the pressure of the air.

teeth, and the whole tongue forcibly kept at a distance from the palate; bring up the tongue to the palate, and allow the tip to separate a little from the teeth, this will expel the air into the space between the fauces and cheeks, and will blow up the cheeks a little; then, acting with the tip of the tongue as a valve, hinder this air from getting back, and depressing the tongue again, more air from the nostrils will get into the mouth, which may be expelled into the space without the teeth as before, and the cheeks will be more inflated. Continue this operation, and the lips will no longer be able to retain it, and it will ooze through as long as the operation is continued. When this has become familiar and easy, take the blow-pipe, and there will be no difficulty in maintaining a blast as uniform as a smith's bellows, breathing all the while through the nostrils. The only difficulty is the holding the pipe. This fatigues the lips; but it may be removed by giving the pipe a convenient shape, a pretty flat oval, and wrapping it round with leather or thread.

Nature of the land and sea-breeze in warm countries.

Another phenomenon depending on the principles already established, is the land and sea-breeze in the warm countries. We have seen that air expands exceedingly by heat; therefore heated air, being lighter than an equal bulk of cold air, must rise in it. If we lay a hot stone in the sunshine in a room, we shall observe the shadow of the stone surrounded with a fluttering shadow of different degrees of brightness, and that this flutter rises rapidly in a column above the stone. If we hold an extinguished candle near the stone, we shall see the smoke move towards the stone, and then ascend from it. Now, suppose an island receiving the first rays of the sun in a perfectly calm morning; the ground will soon be warmed, and will warm the contiguous air. If the island be mountainous, this effect will be more remarkable; because the inclined sides of the hills will receive the light more directly. The midland air will therefore be most warmed. The heated air will rise, and that in the middle will rise fastest; and thus a current of air upwards will begin, which must be supplied by air coming in from all sides, to be heated and to rise in its turn; so that the morning sea-breeze is produced, and continues all day. This current will frequently be reversed during the night, by the air cooling and gliding down the sides of the hills, and we shall have the land-breeze.

Circulation of air in mines.

It is owing to the same cause that we have a circulation of air in mines which have the mouths of their shafts of unequal heights. The temperature under ground is pretty constant through the whole year, while that of the atmosphere is extremely variable. Now, suppose a mine having a long horizontal drift, communicating between two pits or shafts, and that one of these shafts terminates in a valley, while the other opens on the brow of a hill perhaps 100 feet higher. Let us further suppose it summer, and the air heated to 65°, while the temperature of the earth is but 45°; this last will be also the temperature of the air in the shafts and the drift. Now, since air expands nearly 24 parts in 10,000 by one degree of heat, we shall have an odds of pressure at the bottom of the two shafts equal to nearly the 20th part of the weight of a column of air 100 feet high (100 feet being supposed the difference of the heights of the shafts.) This will be about six ounces on every square foot of the section of the shaft. If this pressure could be continued, it would produce a prodigious current of air down the long shafts, along the drift, and up the short shaft. The weight of air acting through 100 feet would communicate to it the velocity of 80 feet per second: divide this by $\sqrt{20}$, that is, by 4·5, and we shall have 18 feet per second for the velocity: this is the velocity of what is called a brisk gale. This pressure would be continued, if the warm air which enters the long shaft were cooled and condensed as fast as it comes in; but this is not the case. It is however cooled and condensed, and a current is produced sufficient to make an abundant circulation of air along the whole passage; and care is taken to dispose the shafts and conduct the passages in such a manner that no part of the mine is out of the circle. When any new lateral drift is made, the renewal of air at its extremity becomes more imperfect as it advances: and when it is carried a certain length, the air stagnates and becomes suffocating, till either a communication can be made with the rest of the mine, or a shaft be made at the end of this drift.

Effects of the pressure of the air.

As this current depends entirely on the difference of temperature between the air below and that above, it must cease when this difference ceases. Accordingly, in the spring and autumn, the miners complain much of stagnation; but in summer they never want a current from the deep pits to the shallow, nor in the winter a current from the shallow pits to the deep ones. It frequently happens also, that in mineral countries the chemical changes which are going on in different parts of the earth occasion differences of temperature sufficient to produce a sensible current.

The nature of what is called the draught in chimneys.

And this naturally leads us to consider a very important effect of the expansion and consequent ascent of air by heat, namely, the drawing, as it is called, of chimneys. The air which has contributed to the burning of fuel must be intensely heated, and will rise in the atmosphere. This will also be the case with much of the surrounding air which has come very near the fire, although not in contact with it. If this heated air be made to rise in a pipe, it will be kept together, and therefore will not soon cool and collapse: thus we shall obtain a long column of light air, which will rise with a force so much the greater as the column is longer or more heated. Therefore the taller we make the chimney, or the hotter we make the fire, the more rapid will be the current, or the draught or suction, as it is injudiciously called, will be so much the greater. The ascensional force is the difference between the weight of the column of heated air in the funnel and a column of the surrounding atmosphere of equal height. We increase the draught, therefore, by increasing the perpendicular height of the chimney. Its length in a horizontal direction gives no increase, but, on the contrary, diminishes the draught by cooling the air before it gets into the effective part of the funnel. We increase the draught also by obliging all the air which enters the chimney to come very near the fuel; therefore a low mantle-piece will produce this effect; also filling up all the spaces on each side of the grate. When much air gets in above the fire, by having a lofty mantle-piece, the general mass of air in the chimney cannot be much heated. Hence it must happen that the greatest draught will be produced by bringing down the mantle-piece to the very fuel; but this converts a fire-place into a furnace, and by thus sending the whole air through the fuel, causes it to burn with great rapidity, producing a prodigious heat; and this producing an increase of ascensional force, the current becomes furiously rapid, and the heat and consumption of fuel immense. If the fire-place be a cube of a foot and a half, and the front closed by a door, so that all the air must enter through the bottom of the grate, a chimney of fifteen or twenty feet high, and sufficiently wide to give passage to all the expanded air which can pass through the fire, will produce a current which will roar like thunder, and a heat sufficient to run the whole inside into a lump of glass.

All that is necessary, however, in a chamber fire-place, is a current sufficiently great for carrying up the smoke and vitiated air of the fuel. And as we want also the enlivening light and flutter of the fire, we give the chimney-piece both a much greater height and width than what is merely necessary for carrying up the smoke, only wishing to have the current sufficiently determinate and steady for counteracting any occasional tendency which it may sometimes have to come into the room. By allowing a greater quantity of air to get into the chimney, heated only to a mode-

Effects of the pressure of the air.

rate degree, we produce a more rapid renewal of the air of the room: did we oblige it to come so much nearer the fire as to produce the same renewal of the air in consequence of a more rapid current, we should produce an inconvenient heat. But in this country, where pit-coal is in general so very cheap, we carry this indulgence to an extreme; or rather we have not studied how to get all the desired advantages with economy. A much smaller renewal of air than we commonly produce is abundantly wholesome and pleasant, and we may have all the pleasure of the light and flame of the fuel at much less expense, by contracting greatly the passage into the vent. The best way of doing this is by contracting the brick-work on each side behind the mantle-piece, and reducing it to a narrow parallelogram, having the back of the vent for one of its long sides. Make an iron plate to fit this hole, of the same length, but broader, so that it may lie sloping, its lower edge being in contact with the foreside of the hole, and its upper edge leaning on the back of the vent. In this position it shuts the hole entirely. Now let the plate have a hinge along the front or lower edge, and fold up like the lid of a chest. We shall thus be able to enlarge the passage at pleasure. In a fire-place fit for a room of 24 feet by 18, if this plate be about 18 inches long from side to side, and folded back within an inch or an inch and a half of the wall, it will allow passage for as much air as will keep up a very cheerful fire; and by raising or lowering this register, the fire may be made to burn more or less rapidly. A free passage of half an inch will be sufficient in weather that is not immoderately cold. The principle on which this construction produces its effect is, that the air which is in the front of the fire, and much warmed by it, is not allowed to get into the chimney, where it would be immediately hurried up the vent, but rises up to the ceiling and is diffused over the whole room. This double motion of the air may be distinctly observed by opening a little of the door and holding a candle in the way. If the candle be held near the floor, the flame will be blown into the room; but if held near the top of the door, the flame will be blown outward.

Description of a stove-grate or chapelle.

But the most perfect method of warming an apartment in the temperate climates, where we can indulge in the cheerfulness and sweet air produced by an open fire, is what we call a stove-grate, and our neighbours on the Continent call a chapelle, from its resemblance to the chapels or oratories in the great churches.

In the great chimney-piece, which, in this case, may be made even larger than ordinary, is set a smaller one fitted up in the same style of ornament, but of a size no greater than is sufficient for holding the fuel. The sides and back of it are made of iron (cast iron is preferable to hammered iron, because it does not so readily calcine), and are kept at a small distance from the sides and back of the main chimney-piece, and are continued down to the hearth, so that the ash-pit is also separated. The pipe or chimney of the stove grate is carried up behind the ornaments of the mantle-piece till it rises above the mantle-piece of the main chimney-piece, and is fitted with a register or damper-plate turning round a traverse axis. The best form of this register is that which we have recommended for an ordinary fire-place, having its axis or joint close at the front; so that when it is open or turned up, the burnt air and smoke striking it obliquely, are directed with certainty into the vent, without any risk of reverberating and coming out into the room. All the rest of the vent is shut up by iron-plates or brick-work out of sight.

The effect of this construction is very obvious. The fuel, being in immediate contact with the back and sides of the grate, heats them to a great degree, and they heat the air contiguous to them. This heated air cannot get up the vent, because the passages above these spaces are shut up. It therefore comes out into the room; some of it goes into the real fire-place and is carried up the vent, and the rest rises to the ceiling and is diffused over the room.

Effects of the pressure of the air.

Effect of its construction.

It is surprising to a person who does not consider it with skill, how powerfully this grate warms a room. Less than one-fourth of the fuel consumed in an ordinary fire-place is sufficient; and this with the same cheerful blazing hearth and salutary renewal of air. It even requires attention to keep the room cool enough. The heat communicated to those parts in contact with the fuel is needlessly great; and it will be a considerable improvement to line this part with very thick plates of cast-iron, or with tiles made of fire-clay which will not crack with the heat. These, being very bad conductors, will make the heat, ultimately communicated to the air, very moderate. If, with all these precautions, the heat should be found too great, it may be brought under perfect management by opening passages into the vent from the lateral spaces. These may be valves or trap-doors moved by rods concealed behind the ornaments.

Thus we have a fire-place under the most complete regulation, where we can always have a cheerful fire without being for a quarter of an hour incommoded by the heat; and we can as quickly raise our fire, when too low, by hanging on a plate of iron on the front, which shall reach as low as the grate. This in five minutes will blow up the fire into a glow; and the plate may be sent out of the room, or set behind the stove-grate out of sight.

The propriety of inclosing the ash-pit is not so obvious; but if this be not done, the light ashes, not finding a ready passage up the chimney, will come out into the room along with the heated air.

Mode of warming apartments by stoves.

Under this head we shall next give a general account and description of the method of warming apartments by stoves. A stove in general is a fire-place shut up on all sides, having only a passage for admitting the air to support the fire, and a tube for carrying off the vitiated air and smoke; and the air of the room is warmed by coming into contact with the outside of the stove and flue. The general principle of construction, therefore, is very simple. The air must be made to come into as close contact as possible with the fire, or even to pass through it, and this in such quantities as just to consume a quantity of fuel sufficient for producing the heat required; and the stove must be so constructed, that both the burning fuel and the air which has been heated by it shall be applied to as extensive a surface as possible of furnace, all in contact with the air of the room; and the heated air within the stove must not be allowed to get into the funnel which is to carry it off till it is too much cooled to produce any considerable heat on the outside of the stove.

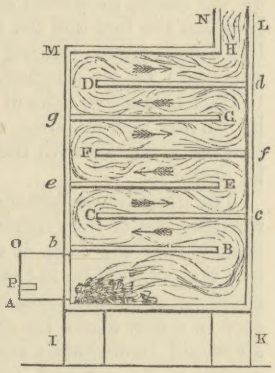
In this temperate climate no great ingenuity is necessary for warming an ordinary apartment; and stoves are made rather to please the eye as furniture than as economical substitutes for an open fire of equal calorific power. But our neighbours on the Continent, and especially towards the north, where the cold of winter is intense and fuel very dear, have bestowed much attention on their construction, and have combined ingenious economy with every elegance of form. Nothing can be handsomer than the stoves of Fayencerie that are to be seen in French Flanders, or the Russian stoves at St. Petersburg, finished in stucco. Our readers will not, therefore, be displeased with a description of them. In this place, however, we shall only consider a stove in general as a subject of pneumatical discussion, and refer our readers to the article STOVE for stoves as articles of domestic accommodation.

General form of a stove.

The general form, therefore, of a stove, and of which all others are only modifications adapted to circumstances of utility or taste, is as follows:—MIKL (fig. 79.) is a quadrangular box of any size in the directions MILK. The inside width from front to back is pretty constant, never less than 10 inches, and rarely extending to 20;

the included space is divided by a great many partitions. The lowest chamber B is the receptacle for the fuel, which lies on the bottom of the stove without any grate; this fire-place has a door AO turning on hinges, and in this door is a very small wicket P: the roof of the fire-place extends to within a very few inches of the farther end, leaving a narrow passage B for the flame. The next partition c C is about eight inches higher, and reaches almost to the other end, leaving a narrow passage for the flame at C. The partitions are repeated above, at the distance of eight inches, leaving passages at the ends, alternately disposed as in the figure; the last of them H communicates with the room vent. This communication may be regulated by a plate of iron, which can be slid across it by means of a rod or handle which comes through the side. The more usual way of shutting up this passage is by a sort of pan or bowl of earthen ware, which is inverted over it with its brim resting in sand contained in a groove formed all round the hole. This damper is introduced by a door in the front, which is then shut. The whole is set on low pillars, so that its bottom may be a few inches from the floor of the room. It is usually placed in a corner, and the apartments are so disposed that their chimneys can be joined in stacks as with us.

Fig. 79.



Some straw or wood shavings are first burnt on the hearth at its farther end. This warms the air in the stove, and creates a determined current. The fuel is then laid on the hearth close by the door, and pretty much piled up. It is now kindled; and the current being already directed to the vent, there is no danger of any smoke coming out into the room. Effectually to prevent this, the door is shut, and the wicket P opened. The air supplied by this, being directed to the middle or bottom of the fuel, quickly kindles it, and the operation goes on.

Aim and effects of this construction.

The aim of this construction is very obvious. The flame and heated air are retained as long as possible within the body of the stove by means of the long passages; and the narrowness of these passages obliges the flame to come in contact with every particle of soot, so as to consume it completely, and thus convert the whole combustible matter of the fuel into heat. For want of this, a very considerable portion of our fuel is wasted by our open fires, even under the very best management. The soot which sticks to our vents is very inflammable, and a pound weight of it will give as much if not more heat than a pound of coal. And what sticks to our vents is very inconsiderable in comparison with what escapes unconsumed at the chimney top. In fires of green wood, peat, and some kinds of pit-coal, nearly one-fifth of the fuel is lost in this way; but in these stoves there is hardly ever any mark of soot to be seen; and even this small quantity is produced only after lighting the fires. The volatile inflammable matters are expelled from parts much heated indeed, but not so hot as to burn; and some of it charred or half-burnt cannot be any further consumed, being enveloped in flame and air already vitiated and unfit for combustion. But when the stove is well heated, and the current brisk, no part of the soot escapes the action of the air.

The hot air retained in this manner in the body of the stove is applied to its sides in a very extended surface. To increase this still more, the stove is made narrower from front to back in its upper part; a certain breadth is necessary below, that there may be room for fuel. If this breadth were preserved all the way up, much heat would be lost, because the heat communicated to the partitions of the stove does no good. By diminishing their breadth, the proportion of useful surface is increased. The whole body of the stove may be considered as a long pipe folded up, and its effect would be the greatest possible if it really were so; that is, if each partition cC, dD, &c. were split into two, and a free passage allowed between them for the air of the room. Something like this will be observed afterwards in some German stoves.

It is with the same view of making an extensive application of a hot surface to the air, that the stove is not built in the wall, not even in contact with it, nor with the floor; for by its detached situation, the air in contact with the back, and with the bottom, where it is hottest, is warmed, and contributes at least one-half of the whole effect; for the great heat of the bottom makes its effect on the air of the room at least equal to that of the two ends. Sometimes a stove makes part of the wall between two small rooms, and is found sufficient.

It must be remarked, on the whole, that the effect of a stove depends much on keeping in the room the air already heated by it. This is so remarkably the case, that a small open fire in the same room will be so far from increasing its heat, that it will greatly diminish it; it will even draw the warm air from a suite of adjoining apartments. This is distinctly observed in the houses of the English merchants in St. Petersburg; their habits of life in Britain make them uneasy without an open fire in their sitting rooms; and this obliges them to heat all their stoves twice a-day, and their houses are cooler than those of the Russians, who heat them only once. In many German houses, especially of the lower class, the fire-place of the stove does not open into the room, but into the yard or a lobby, where all the fires are lighted and tended; by this means is avoided the expense of warm air which must have been carried off by the stove; but it is evident, that this must be very unpleasant, and cannot be wholesome. We must breathe the same quantity of stagnant air loaded with all the vapours and exhalations which must be produced in every inhabited place. Going into one of these houses from the open air, is like putting one's head into a stew-pan or under a pie-crust, and quickly nauseates us who are accustomed to fresh air and cleanliness. In these countries it is a matter almost of necessity, to fumigate the rooms with frankincense and other gums burnt. The censer in ancient worship was in all probability an utensil introduced by necessity for sweetening or rendering tolerable the air of a crowded place; and it is a constant practice in the Russian houses for a servant to go round the room after dinner, waving a censer with some gums burning on bits of charcoal.

Of hot walls in gardening, &c.

The account now given of stoves for heating rooms, and of the circumstances which must be attended to in their construction, will equally apply to hot walls in gardening, whether within or without doors. The only new circumstance which this employment of a flue introduces, is the attention which must be paid to the equability of the heat, and the gradation which must be observed in different parts of the building. The heat in the flue gradually diminishes as it recedes from the fire-place, because it is continually giving out heat to the flue. It must therefore be so conducted through the building by frequent returns, that in every part there may be a mixture of warmer and cooler branches of the flue, and the final chimney should be close by the fire-place. It would, however, be improper to run the flue from the end of the floor up to the ceiling, where the second horizontal pipe would be placed, and then return it downward again and make the third horizontal flue adjoining to the first, &c. This would make the middle of the wall the coldest. If it is the flue of a greenhouse, this would be highly improper, because the upper part of the wall can be very little employed; and in this case it is better to allow the flue to proceed gradually up the wall in its different returns, by which the lowest part would be the warmest, and the heated air will ascend among the pots and plants; but in a hot wall, where the trees are to receive heat by contact, some approximation to the above method may be useful. In the hypocausta and fudaria of the Greeks and Romans, the flue was conducted chiefly under the floors.

Malt-kilns a species of stove.

Malt-kilns are a species of stove which merit our attention. Many attempts have been made to improve them on the principle of flue stoves; but they have been unsucessful, because heat is not what is chiefly wanted in malting; it is a copious current of very dry air to carry off the moisture.

Of the current of air in melting furnaces.

All that is to be attended to in the different kinds of melting furnaces is, that the current of air be sufficiently rapid, and that it be applied in as extensive a surface as possible to the substance to be melted. The more rapid the current it is the hotter, because it is consuming more fuel; and therefore its effect increases in a higher proportion than its rapidity. It is doubly effectual if twice as hot; and if it then be twice as rapid, there is twice the quantity of doubly hot air applied to the subject; it would therefore be four times more powerful. This is procured by raising the chimney of the furnace to a greater height. The close application of it to the subject can hardly be laid down in general terms, because it depends on the precise circumstances of each case.

Current in reverberatory furnaces.

In reverberatory furnaces, such as refining furnaces for gold, silver, and copper, the flame is made to play over the surface of the melted metal. This is produced entirely by the form of the furnace, by making the arch of the furnace as low as the circumstances of the manipulation will allow. See Furnace. Experience has pointed out in general the chief circumstances of their construction, viz. that the fuel should be at one end on a grate, through which the air enters to maintain the fire; and that the metal should be placed on a level floor between the fuel and the tall chimney which produces the current. But there is no kind of furnace more variable in its effect, and almost every place has a small peculiarity of construction, on which its preeminence is rested. This has occasioned many whimsical varieties in their form. This uncertainty seems to depend much on a circumstance rather foreign to our present purpose; but as we do not observe it taken notice of by mineralogical writers, we beg leave to mention it here. It is not heat alone that is wanted in the refining of silver by lead, for instance. We must make a continual application to its surface of air, which has not contributed to the combustion of the fuel. Any quantity of the hottest air, already saturated with the fuel, may play on the surface of the metal for ever, and keep it in the state of most perfect fusion, but without refining it in the least. Now, in the ordinary construction of a furnace, this is much the case. If the whole air has come in by the grate, and passed through the middle of the fuel, it can hardly be otherwise than nearly saturated with it; and if air be also admitted by the door, which is generally done or something equivalent, the pure air lies above the vitiated air, and during the passage along the horizontal part of the furnace, and along the surface of the metal, it still keeps above it, at least there is nothing to promote their mixture. Thus the metal does not come into contact with air fit to act on the base metal and calcine it, and the operation of refining goes on slowly. Trifling circumstances in the form of the arch or canal may tend to promote the jumbling of the airs together, and thus render the operation more expeditious; and as these are but ill understood, or perhaps this circumstance not attended to, no wonder that we see these considered as so many nostrums of great importance. It were therefore worth while to try the effect of changes in the form of the roof directed to this very circumstance. Perhaps some little prominence down from the arch of the reverberatory would have this effect, by suddenly throwing the current into confusion. If the additional length of passage do not cool the air too much, we should think that if there were interposed between the fuel and the refining floor a passsage twisted like a cork-screw, making just half a turn, it would be most effectual; for we imagine, that the two airs, keeping each to their respective sides of the passage, would by this means be turned upside down, and that the pure stratum would now be in contact with the metal, and the vitiated air would be above it.

Current in the glass-house furnaces.

The glass-house furnace exhibits the chief variety in the management of the current of heated air. In this it is necessary that the hole at which the workman dips his pipe into the pot shall be as hot as any part of the furnace. This could never be the case, if the furnace had a chimney situated in a part above the dipping-hole; for in this case cold air would immediately rush in at the hole, play over the surface of the pot, and go up the chimney. To prevent this the hole itself is made the chimney; but as this would be too short, and would produce very little current and very little heat, the whole surface is set under a tall dome. Thus the heated air from the real furnace is confined in this dome, and constitutes a high column of very light air, which will therefore rise with great force up the dome, and escape at the top. The dome is therefore the chimney, and will produce a draught or current proportioned to its height. Some are raised above a hundred feet. When all the doors of this house are shut, and thus no supply given except through the fire, the current and heat become prodigious. This, however, cannot be done, because the workmen are in this chimney, and must have respirable air. But notwithstanding this supply by the house-doors, the draught of the real furnace is vastly increased by the dome, and a heat produced sufficient for the work, and which could not have been produced without the dome.

Cotterel's improvement for melting iron from the ore.

This has been applied with great ingenuity and effect to a furnace for melting iron from the ore, and an iron finery, both without a blast. The common blast iron furnace is well known. It is a tall cone with the apex undermost. The ore and fluxes are thrown into this cone mixed intimately with the fuel till it is full, and the blast of most powerful bellows is directed into the bottom of this cone through a hole in the side. The air is thrown in with such force, that it makes its way through the mass of matter, kindles the fuel in its passage, and fluxes the materials, which then drop down into a receptacle below the blast-hole, and thus the passage for the air is kept unobstructed. It was thought impossible to produce or maintain this current without bellows; but Mr. Cotterel, an ingenious founder, tried the effect of a tall dome placed over the mouth of the furnace, and though it was not half the height of many glass-house domes it had the desired effect.

Currents of air applied to free mines, &c. of noxious air.

The last application which we shall make of the currents produced by heating the air is to the freeing mines, ships, prisons, &c. from the damp and noxious vapours which frequently infest them. As a drift or work is carried on in the mine, let a trunk of deal boards, about six or eight inches square, be laid along the bottom of the drift, communicating with a trunk carried up in the corner of one of the shafts. Let the top of this last trunk open into the ash-pit of a small furnace, having a tall chimney. Let fire be kindled in the furnace; and when it is well heated, shut the fire-place and ash-pit doors. There being no other supply for the current produced in the chimney of this furnace, the air will flow into it from the trunk, and will bring along with it all the offensive vapours. This is the most effectual method yet found out. In the same manner may trunks be conducted into the ash-pit of a furnace from the cells of a prison or the wards of an hospital.

In the account which we have been giving of the management of air in furnaces and common fires, we have frequently mentioned the immediate application of air to the burning fuel as necessary for its combustion. This is a general fact.

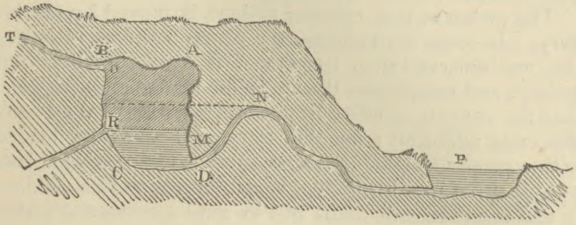
Air necessary for the combustion of fuel.

In order that any inflammable body may be readily inflamed, and its combustible matter consumed and ashes produced, it is not enough that the body be made hot. A piece of charcoal inclosed in a box of iron may be kept red hot for ever, without wasting its substance in the smallest degree. It is further necessary that it be in contact with a particular species of air, which constitutes nearly one-fourth of the air of the atmosphere, viz. the vital air or oxygen of Lavoisier. It was called empyreal air by Scheele, who first observed its indispensable use in maintaining fire; and it appears, that, in contributing to the combustion of an inflammable body, this air combines with some of its ingredients, and becomes fixed air, suffering the same change as by the breathing of animals. Combustion may therefore be considered as a union of the inflammable body with oxygen. This doctrine was first promulgated by the celebrated Dr. Hooke in his *Micrographia*, published in 1660, and afterwards improved in his *Treatise on Lamps*. It is now completely established, and considered as a new discovery. It is for this reason, that in fire-places of all kinds we have directed the construction, so as to produce a close application of the air to the fuel. It is quite needless at this day to enter into the discussions which formerly occupied philosophers about the manner in which the pressure and elasticity of the air promoted combustion. Many experiments were made in the seventeenth century by the first members of the Royal Society, to discover the office of air in combustion. It was thought that the flame was extinguished in rare air for want of a pressure to keep it together; but this did not explain its extinction when the air was not renewed. These experiments were long retained in courses of experimental philosophy, as they were judiciously styled; but they neither gave information, nor tended to the illustration of any pneumatical doctrine: they are of course omitted in this place. In short, it is now fully established, that it is not a mechanical but a chemical phenomenon. We can only inform the chemist, that a candle will consume faster in the low countries than in the elevated regions of Quito and Gondar, because the air is nearly one half denser below, and will act proportionally faster in decomposing the candle.

Curious effect of the pressure of the air.

We shall conclude this part of our subject with the explanation of a curious phenomenon observed in many places. Certain springs or fountains are observed to have periods of repletion and scantiness, or seem to ebb and flow at regular intervals; and some of these periods are of a complicated nature. Thus a well will have several returns of high and low water, the difference of which gradually increases to a maximum, and then diminishes, just as we observe in the ocean. A very ingenious and probable explanation of this has been given in No. 424 of the *Philosophical Transactions*, by Mr. Atwell.

Fig. 90.



Let ABCD (fig. 90,) represent a cavern, into which water is brought by the subterraneous passage OT. Let it have an outlet MNP, of a crooked form, with its highest part N considerably raised above the bottom of the cavern, and thence sloping downwards into lower ground, and terminating in an open well at P. Let the dimensions of this canal be such that it will discharge much more water than is supplied by TO. All this is very natural, and may be very common. The effect of this arrangement will be a remitting spring at P; for when the cavern is filled higher than the point N, the canal MNP will act as a syphon; and, by the conditions assumed, it will discharge the water faster than TO supplies it; it will therefore run it dry, and then the spring at P will cease to furnish water. After some time the cavern will again be filled up to the height N, and the flow at P will recommence.

If, besides this supply, the well P also receive water from a constant force, we shall have a reciprocating spring. The situation and dimensions of this syphon canal, and the supply of the feeder, may be such, that the efflux at P will be constant. If the supply increase in a certain degree, a reciprocation will be produced at P with very short intervals; if the supply diminishes considerably, we shall have another kind of reciprocation with great intervals and great differences of water.

If the cavern have another simple outlet R, new varieties will be produced in the spring P, and R will afford a copious spring. Let the mouth of R, by which the water enters into it from the cavern, be lower than N, and let the supply of the feeding spring be no greater than R can discharge, we shall have a constant spring from R, and P will give no water. But suppose that the main feeder increases in winter or in rainy seasons, but not so much as will supply both P and R, the cavern will fill till the water gets over N, and R will be running all the while; but soon after P has begun to flow, and the water in the cavern sinks below R, the stream from R will stop. The cavern will be emptied by the syphon canal MNP, and then P will stop. The cavern will then begin to fill, and when near full R will give a little water, and soon after P will run and R stop as before, &c. Desaguliers shows (vol. ii. p. 177, &c.) in what manner a prodigious variety of periodical ebbs and flows may be produced by underground canals, which are extremely simple and probable.

Account of some pneumatic engines.

We shall conclude this article with the descriptions of some pneumatical machines or engines which have not been particularly noticed under their names in the former volumes of this work.

Bellows are of most extensive and important use; and it will be of service to describe such as are of uncommon construction and power, sufficient for the great operations in metallurgy.

It is not the impulsive force of the blast that is wanted in most cases, but merely the copious supply of air, to produce the rapid combustion of inflammable matter; and the service would be better performed in general if this could be done with moderate velocities, and an extended surface. What are called air-furnaces, where a considerable surface of inflammable matter is acted on at once by the current which the mere heat of the expended air has produced, are found more operative in proportion to the air expended than blast furnaces animated by bellows; and we doubt not but that the method proposed by Mr. Cotterel, which we have already mentioned, of increasing this current in a melting furnace by means of a dome, will in time supersede the blast furnaces. There is indeed a great impulsive force required in some cases; as for blowing off the scoriæ from the surface of silver or copper in refining furnaces, or for keeping a clear passage for the air in the great iron furnace.

In general, however, we cannot procure this abundant supply of air any other way than by giving it a great velocity by means of a great pressure, so that the general construction of bellows is pretty much the same in all kinds.

The air is admitted into a very large cavity, and then expelled from it through a small hole.

The furnaces at the mines having been greatly enlarged, it was necessary to enlarge the bellows also; and the leathern bellows becoming exceedingly expensive, wooden ones were substituted in Germany about the beginning of the seventeenth century, and from them became general throughout Europe. They consist of a wooden box ABCPFE, fig. 91, which has its top and two sides flat or straight, and the end BAE formed into an arched or cylindrical surface, of which the line FP at the other end is the axis. This box is open below, and receives within it the shallow box KHGNML, fig. 92, which exactly fills it. The line FP of the one coincides with FM of the other, and along this line is a set of hinges on which the upper box turns as it rises and sinks. The lower box is made fast to a frame fixed in the ground. A pipe OQ proceeds from the end of it, and terminates at the furnace, where it ends in a small pipe called the *tewer* or *tuyere*. This lower box is open above, and has in its bottom two large valves V, V, fig. 93, opening inwards. The conducting pipe is sometimes furnished with a valve opening outwards, to prevent burning coals from being sucked into the bellows when the upper box is drawn up. The joint along PF is made tight by thin leather nailed along it. The sides and ends of the fixed box are made to fit the sides and curved end of the upper box, so that this last can be raised and lowered round the point FP without sensible friction, and yet without suffering much air to escape; but as this would not be sufficiently air-tight by reason of the shrinking and warping of the wood, a farther contrivance is adopted. A slender lath of wood, divided into several joints, and covered on the outer edge with very soft leather, is laid along the upper edges of the sides and ends of the lower box. This lath is so broad, that when its inner edge is even with the inside of the box, its outer edge projects about an inch. It is kept in this position by a number of steel wires, which are driven into the bottom of the box, and stand up touching the sides, as represented in fig. 94, where *a b c* are the wires, and *e* the lath, projecting over the outside of the box. By this contrivance the laths are pressed close to the sides and curved end of the moveable box, and the spring wires yield to all their inequalities. A bar of wood RS, fig. 91, is fixed to the upper board, by which it is either raised by machinery, to sink again by its own weight, having an additional load laid on it, or it is forced downward by a crank or wiper of the machinery, and afterwards raised.

Fig. 91.

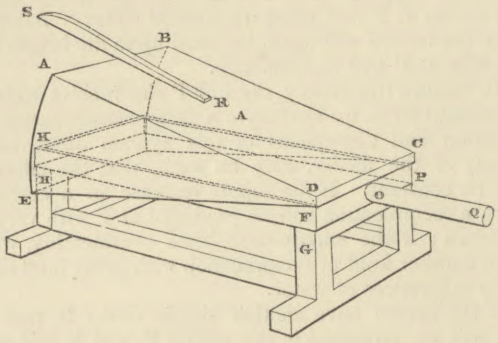


Fig. 92.

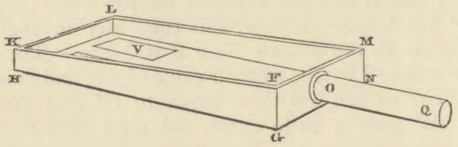

Fig. 93.

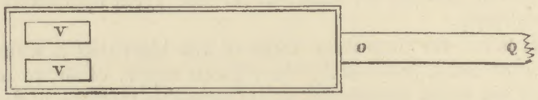

Fig. 94.

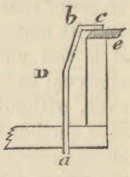


The operation here is precisely similar to that of blowing with a chamber-bellows. When the board is lifted up, the air enters by the valves V, V, fig. 93, and is expelled at the pipe OQ by depressing the boards. There is therefore no occasion to insist on this point.

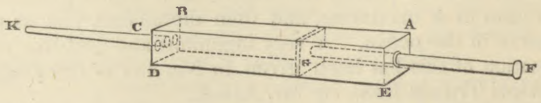
These bellows are made of a very great size, AD being 16 feet, AB five feet, and the circular end AE also five feet. The rise, however, is but about 3 or $3\frac{1}{2}$ feet. They expel at each stroke about 90 cubic feet of air, and they make about 8 strokes per minute.

Such are the bellows in general use on the continent. We have adopted a different form in this kingdom, which seems much preferable. We use an iron or wooden cylinder, with a piston sliding along it. This may be made with much greater accuracy than the wooden boxes, at less expense, if of wood, because it may be of cooper's work, held together by hoops; but the great advantage of this form is its being more easily made air-tight. The piston is surrounded with a broad strap of thick and soft leather, and it has around its edge a deep groove, in which is lodged a quantity of wool. This is called the packing or stuffing, and keeps the leather very closely applied to the inner surface of the cylinder. Iron cylinders may be very neatly bored and smoothed, so that the piston, even when very tight, will slide along it very smoothly. To promote this, a quantity of black lead is ground very fine with water, and a little of this is smeared on the inside of the cylinder from time to time.

The cylinder has a large valve, or sometimes two, in the bottom, by which the atmospheric air enters when the piston is drawn up. When the piston is thrust down, this air is expelled along a pipe of great diameter, which terminates in the furnace with a small orifice.

This is the simplest form of bellows which can be conceived. It differs in nothing but size from the bellows used by the rudest nations. The Chinese smiths have a bellows very similar, being a square pipe of wood ABCDE, fig. 95, with a square board G which exactly fits it, moved by the handle FG. At the farther end is the blast pipe CK, and on each side of it a valve in the end of the square pipe, opening inwards. The piston is sufficiently tight for their purposes without any leathering.

Fig. 95.

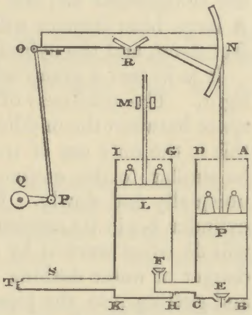


The piston of this cylinder bellows is moved by machinery. In some blast engines the piston is simply raised by the machine, and then let go, and it descends by its own weight, and compresses the air below it to such a degree, that the velocity of efflux becomes constant, and the piston descends uniformly; for this purpose it must be loaded with a proper weight. This produces a very uniform blast, except at the very beginning, whilst the piston falls suddenly and compresses the air; but in most engines the piston rod is forced down the cylinder with a determined motion, by means of a beam, crank, or other contrivance. This gives a more unequal blast, because the motion of the piston is necessarily slow in the beginning and end of the stroke, and quicker in the middle.

But in all it is plain that the blast must be desultory. It ceases while the piston is rising; for this reason it is usual to have two cylinders, as it was formerly usual to have two bellows which worked alternately. Sometimes three or four are used, as at the Carron iron-works. This makes a blast abundantly uniform.

But an uniform blast may be made with a single cylinder, by making it deliver its air into another cylinder, which has a piston exactly fitted to its bore, and loaded with a sufficient weight. The blowing cylinder ABCD, fig. 96, has its piston P worked by a rod NP, connected by double chains with the arched head of the working beam NO, moving round a gudgeon at R. The other end O of this beam is connected by the rod OP, with the crank PQ of a wheel machine; or it may be connected with a piston of a steam-engine, &c. &c. The blowing cylinder has a valve or valves E in its bottom, opening inwards. There proceeds from it a large pipe CF, which enters the regulating cylinder GHKI, and has a valve at top to prevent the air from getting back into the blowing cylinder. It is evident that the air forced into this cylinder must raise its piston L, and that it must afterwards descend, while the other piston is rising. It must descend uniformly, and make a perfectly equable blast.

Fig. 96.



Observe, that if the piston L be at the bottom when the machine begins to work, it will be at the bottom at the end of every stroke if the *tuyere* T emits as much air as the cylinder ABCD furnishes; nay, it will lie a while at the bottom, for, while it was rising, air was issuing through T. This would make an interrupted blast. To prevent this, the orifice T must be lessened; but then there will be a surplus of air at the end of each stroke, and the piston L will rise continually, and at last get to the top, and allow air to escape. It is just possible to adjust circumstances, so that neither shall happen. This is done easier by putting a stop in the way of the piston, and putting a valve on the piston, or on the conducting pipe KST, loaded with a weight a little superior to the intended elasticity of the air in the cylinder. Therefore, when the piston is prevented by the stop from rising, the snifting valve, as it is called, is forced open, the superfluous air escapes, and the blast preserves its uniformity.

It may be of use to give the dimensions of a machine of this kind, which worked for many years at a very great furnace, and given satisfaction.

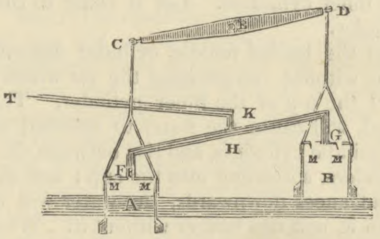
The diameter of the blowing cylinder is 5 feet, and the length of the stroke is 6. Its piston is loaded with $3\frac{1}{2}$ tons. It is worked by a steam-engine whose clyinder is 3 feet 4 inches wide, with a six-feet stroke. The regulating cylinder is 8 feet wide, and its piston is loaded with $8\frac{1}{2}$ tons, making about 2.63 pounds on the square inch; and it is very nearly in equilibrio with the load on the piston of the blowing cylinder. The conducting pipe KST is 12 inches in diameter, and the orifice of the tuyere was $\frac{5}{8}$ths of an inch when the engine was erected, but it has gradually enlarged by reason of the intense heat to which it is exposed. The snifting valve is loaded with 3 pounds on the square inch.

When the engine worked briskly, it made 18 strokes per minute, and there was always much air discharged by the snifting valve. When the engine made 15 strokes per minute, the snifting valve opened but seldom, so that things were nearly adjusted to this supply. Each stroke of the blowing cylinder sent in 118 cubic feet of common air. The ordinary pressure of the air being supposed $14\frac{3}{4}$ pounds on an inch, the density of the air in the regulating cylinder must be $\frac{14.75+2.63}{14.75}$, $=1.1783$, the natural density being 1.

This machine gives an opportunity of comparing the expense of air with the theory. It must, at the rate of 15 strokes, expel 30 cubic feet of air in a second through a hole of $1\frac{5}{8}$ inches in diameter. This gives a velocity of near 2000 feet per second, and of more than 1600 feet for the condensed air. This is vastly greater than the theory can give, or is indeed possible; for air does not rush into a void with so great velocity. It shows with great evidence, that a vast quantity of air must escape round the two pistons. Their united circumferences amount to above 40 feet, and they move in a dry cylinder. It is impossible to prevent a very great loss. Accordingly, a candle held near the edge of the piston L has its flame very much disturbed. This case, therefore, gives no hold for a calculation; and it suggests the propriety of attempting to diminish this great waste.

This has been very ingeniously done, in part at least, at some other furnaces. At a certain foundery, near Glasgow, the blowing cylinder, also worked by a steam-engine, delivers its air into a chest without a bottom, which is immersed in a large cistern of water, and supported at a small height from the bottom of the cistern, and has a pipe from its top leading to the tuyere. The water stands about five feet above the lower brim of the regulating air-chest, and by its pressure gives the most perfect uniformity of blast, without allowing a particle of air to get off by any other passage besides the tuyere. This is a very effectual regulator, and must produce a great saving of power, because a smaller blowing cylinder will thus supply the blast. We must observe, that the loss round the piston of the blowing cylinder remains undiminished.

Fig. 97.



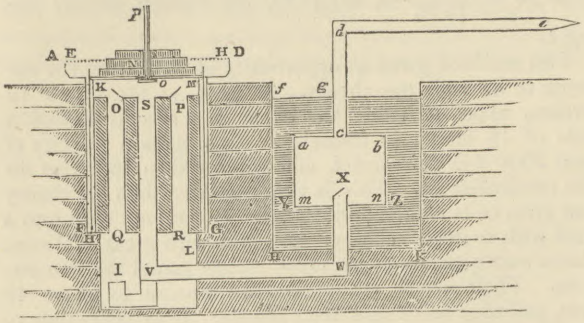
A blowing machine was erected many years ago at Chastillon in France on a principle considerably different, and which must be perfectly air-tight throughout. Two cylinders A, B, (fig. 97) loaded with great weights, were suspended at the ends of the lever CD, moving round the gudgeon E. From the top F, G of each there was a large flexible pipe which united in H, from whence a pipe KT led to the tuyere T. There were valves at F and G opening outwards, or into the flexible pipes; and other valves M, M, adjoining to them in the top of each cylinder, opening inwards, but kept shut by a slight spring. Motion was given to the lever by a machine. The operation of this blowing machine is evident. When the cylinder A was pulled down, or allowed to descend, the water, entering at its bottom, compressed the air, and forced it along the passage FHKT. In the mean time, the cylinder B was rising, and the air entered by the valve M. We see that the blast will be very unequal, increasing as the cylinder is immersed deeper. It is needless to describe this machine more particularly, because we shall give an account of one which we think per-

Pneumatic engines

fect in its kind, and which leaves hardly any thing to be desired in a machine of this sort.

ABCD (fig. 98) is an iron cylinder, truly bored within, and evasated a-top like a cup. EFGH is another, truly turned both without and within, and a small matter less than the inner diameter of the first cylinder. This cylinder is close above and hangs from the end of a lever moved by a machine. It is also loaded with weights at N. KILM is a third cylinder, whose outside diameter is somewhat less than the inside diameter of the second. This inner cylinder is fixed to the same bottom with the outer cylinder. The middle cylinder is loose, and can move up and down between the outer and inner cylinders without rubbing on either of them. The inner cylinder is perforated from top to bottom by three pipes OQ, SV, PR. The pipes OQ, PR have valves at their upper ends O, P, and communicate with the external air below. The pipe SV has a horizontal part VW, which again turns upwards, and has a valve at top X. This upright part WX is in the middle of a cistern of water *fhkg*. Into this cistern is fixed an air-chest *a* YZ *b*, open below, and having at top a pipe *cde* terminating in the tuyere at the furnace.

Fig. 98.



When the machine is at rest, the valves X, O, P, are shut by their own weights, and the air-chest is full of water. When things are in this state, the middle cylinder EFGH is drawn up by the machinery till its lower brims F and G are equal with the top KM of the inner cylinder. Now pour in water or oil between the outer and middle cylinders; and it will run down and fill the space between the outer and inner cylinders. Let it come to the top of the inner cylinder.

Now, let the loaded middle cylinder descend. It cannot do this without compressing the air which is between its top and the top of the inner cylinder. This air being compressed, will cause the water to descend between the inner and middle cylinders, and rise between the middle and outer cylinders, spreading into the cup; and as the middle cylinder advances downwards, the water will descend farther within it, and rise farther without it. When it has got so far down, and the air has been so much compressed, that the difference between the surface of the water on the inside and outside of this cylinder is greater than the depth of water between X and the surface of the water *fg*, air will go out by the pipe SVW, and will lodge in the air-chest, and will remain there if *c* be shut, which we shall suppose for the present. Pushing down the middle cylinder till the partition touch the top of the inner cylinder, all the air which was formerly between them will be forced into the air-chest, and will drive out water from it. Draw up the middle cylinder, and the external air will open the valves O, P, and again fill the space between the middle and inner cylinders; for the valve X will shut, and prevent the regress of the condensed air. By pushing down the middle cylinder a second time, more air will be forced into the air-chest, and it will at last escape by getting out between its brims Y, Z, and the bottom of the cistern; or if we open the passage *c*, it will pass along the conduit *c d e* to the tuyere, and form a blast.

The operation of this machine is similar to Mr. Haskins's quicksilver pump, described by Desaguliers.[1] The force which condenses the air is the load on the middle cylinder. The use of the water between the inner and outer cylinders, is to prevent this air from escaping; and the inner cylinder thus performs the office of a piston, having no friction. It is necessary that the length of the outer and middle cylinders be greater than the depth of the regulator-cistern, that there may be a sufficient height for the water to rise between the middle and outer cylinders, to balance the compressed air, and oblige it to go into the air-chest. A large blast-furnace will require the regulator-cistern five feet deep, and the cylinders about six or seven feet long.

It is in fact a pump without friction, and is perfectly air-tight. The quickness of its operation depends on the small space between the middle cylinder and the two others; and this is the only use of these two. Without these it would be similar to the engine at Chastillon, and operate more unequally and slowly. Its only imperfection is, that if the cylinder begin its motion of ascent or descent rapidly, as it will do when worked by a steam engine, there will be some danger of water dashing over the top of the inner cylinder, and getting into the pipe SV; but should this happen, an issue can easily be contrived for it at V, covered with a loaded valve *v*. This will never happen if the cylinder is moved by a crank. One blowing cylinder only is represented here, but two may be used.

We do not hesitate in recommending this form of bellows as the most perfect of any, and fit for all uses where standing bellows are required. They will be cheaper than any other sort for common purposes. For a common smith's forge they may be made with square wooden boxes instead of cylinders. They are also easily repaired. They are perfectly tight; and they may be made with a blast almost perfectly uniform, by making the cistern in which the air-chest stands, of considerable dimensions. When this is the case, the height of water, which regulates the blast, will vary very little.

This may suffice for an account of blast machines. The leading parts of their construction have been described as far only as was necessary for understanding their operation, and enabling an engineer to erect them in the most commodious manner. Views of complete machines might have amused, but they would not have added to our reader's information.

But the account is imperfect unless we show how their parts may be so proportioned that they shall perform what is expected from them. The engineer should know what size of bellows, and what load on the board or piston, and what size of tuyere, will give the blast which the service requires, and what force must be employed to give them the necessary degree of motion. We shall accomplish these purposes by considering the efflux of the compressed air through the tuyere. The propositions formerly delivered will enable us to ascertain this.

That we may proportion everything to the power employed, we must recollect, that if the piston of a cylinder employed for expelling air, be pressed down with any force p, it must be considered as superadded to the atmospheric pressure P on the same piston, in order that we may compare the velocity v of efflux with the known velocity V with which air rushes into a void. By what has been formerly delivered, it appears that this velocity $v = V \times \sqrt{\frac{p}{P+p}}$, where P is the pressure of the atmosphere on the piston, and p the additional load laid on it. This velocity is expressed in feet per second; and, when multiplied by the area of the orifice (also expressed in square feet) it will give us the cubical feet of condensed air expelled in a second; but the bellows are always to be filled again with common air, and therefore we want to know the quantity of common air which will be expelled; for it is this which determines the number of strokes which must be made in a minute, in order that the proper supply may be obtained. Therefore recollect that the quantity expelled from a given orifice with a given velocity, is in the proportion of the density; and that when D is the density of common air produced by the pressure P, the density d produced by the pressure $P+p$, is $D \times \frac{P+p}{P}$; or if D be made 1, we have $d = \frac{P+p}{P}$.

---

[1] *Experimental Philosophy*, vol. ii. p. 491; and *Philosophical Transactions*, 1728, vol. xxxii. p. 5.

Therefore, calling the area of the orifice expressed in square feet O, and the quantity of common air, or the cubic feet expelled in a second Q, we have $Q = V \times O \times \sqrt{\frac{p}{P+p}} \times \frac{P+q}{P}$.

It will be sufficiently exact for all practical purposes, to suppose P to be 15 pounds on every square inch of the piston; and p is then conveniently expressed by the pounds of additional load on every square inch. We may also take $V = 1332$ feet.

As the orifice through which the air is expelled is generally very small, never exceeding three inches in diameter, it will be more convenient to express it in square inches; which being the $\frac{1}{144}$th of a square foot, we shall have the cubic feet of common air expelled in a second, or $Q = \frac{1332}{144} O \sqrt{\frac{p}{P+p}} \times \frac{P+p}{P}, = O \times 9{\cdot}25 \times \sqrt{\frac{p}{P+p}} \times \frac{P+p}{P}$; and this seems to be as simple an expression as we can obtain.

This will perhaps be illustrated by taking an example in numbers. Let the area of the piston be four square feet, and the area of the round hole through which the air is expelled, be two inches, its diameter being 1.6, and let the load on the piston be 1728 pounds; this is three pounds on every square inch. We have $P=15$, $p=3$, $P+p=18$, and $O=2$; therefore we will have $Q = 2 \times 9.25 \times \sqrt{\frac{3}{18}} \times \frac{18}{15}, = 9.053$ cubic feet of common air expelled in a second. This will however be diminished at least one-third by the contraction of the jet; and therefore the supply will not exceed six cubic feet per second. Supposing therefore that this blowing machine is a cylinder or prism of this dimension in its section, the piston so loaded would, after having compressed the air, descend about 15 inches in a second. It would first sink one-fifth of the whole length of the cylinder pretty suddenly, till it had reduced the air to the density $\frac{18}{15}$, and would then descend uniformly at the above rate, expelling six cubic feet of common air in a second.

The computation is made much in the same way for bellows of the common form, with this additional circumstance, that as the loaded board moves round a hinge at one end, the pressure of the load must be calculated accordingly. The computation, however, becomes a little intricate, when the form of the loaded board is not rectangular. It is almost useless when the bellows have flexible sides, either like smith's bellows or like organ bellows, because the change of figure during their motion makes continual variation on the compressing powers. It is therefore chiefly with respect to the great wooden bellows, of which the upper board slides down between the sides, that the above calculation is of service.

The propriety, however, of this piece of information is evident: we do not know precisely the quantity of air necessary for animating a furnace; but this calculation tells us what force must be employed for expelling the air that may be thought necessary. If we have fixed on the strength of the blast, and the diameter of the cylinder, we learn the weight with which the piston must be loaded; the length of the cylinder determines its capacity, the above calculation tells the expense per second; hence we have the time of the piston's coming to the bottom. This gives us the number of strokes per minute. The load must be lifted up by the machine this number of times, making the time of ascent precisely equal to that of descent; otherwise the machine will either catch and stop the descent of the piston, or allow it to lie inactive for a while of each stroke. These circumstances determine the labour to be performed by the machine, and it must be constructed accordingly. Thus the engineer will not be affronted by its failure, nor will he expend needless power and cost.

In machines which force the piston or bellows board with a certain determined motion, different from what arises from their own weight, the computation is extremely intricate. When a piston moves by a crank, its motion at the beginning and end of each stroke is slow, and the compression and efflux is continually changing. We can however approximate to a statement of the force required.

Every time the piston is drawn up, a certain space of the cylinder is filled again with air of the common density; and this is expelled during the descent of the piston. A certain number of cubic feet of common air is therefore expelled with a velocity which perhaps continually varies; but there is a medium velocity with which it might have been uniformly expelled, and a pressure corresponding to this velocity. To find this, divide the area of the piston by the area of the blast-hole (or rather by this area multiplied by 0·613, in order to take in the effect of the contracted jet), and multiply the length of the stroke performed in a second by the quotient arising from this division; the product is the medium velocity of the air (of the natural density). Then find by calculation the height through which a heavy body must fall in order to acquire this velocity; this is the height of a column of homogeneous air which would expel it with this velocity. The weight of this column is the least force that can be exerted by the engine: but this force is too small to overcome the resistance in the middle of the stroke, and it is too great even for the end of the stroke, and much too great for the beginning of it. But if the machine is turned by a very heavy water-wheel, this will act as a regulator, accumulating in itself the superfluous force during the too favourable positions of the crank, and exerting it by its *vis insita* during the time of greatest effort. A force not greatly exceeding the weight of this column of air will therefore suffice. On the other hand, if the strength of the blast be determined, which is the general state of the problem, this determines the degree of condensation of the air, and the load on the square inch of the piston, or the mean force which the machine must exert on it. A table, which will be given presently, determines the cubic feet of common air expelled in a second, corresponding to this load. This combined with the proposed dimensions of the cylinder, will give the descent of the piston or the length of the stroke.

These general observations apply to all forms of bellows; and without a knowledge of them no person can erect a machine for working them without total uncertainty or servile imitation. In order, therefore, that they may be useful to such as are not accustomed to the management of even these simple formulæ, we insert the following short table of the velocity and quantity of air discharged from a cylinder whose piston is loaded with the pounds contained in the first column on every square inch. The second column contains the velocity with which the *condensed air*

Pneumatic engines.

rushes out through any *small* hole; and the third column is the cubic feet discharged from a hole whose area is a square inch; column fourth contains the mean velocity of air of the common density; and column fifth is the cubic feet of common air discharged; the sixth column is the height in inches at which the force of the blast would support a column of water if a pipe were inserted into the side of the cylinder. This is an extremely proper addition to such machines, showing at all times the power of the machines, and teaching us what intensity of blast is employed for different purposes. The table is computed from the supposition that the ordinary pressure of the air is 15 pounds on a square inch. This is somewhat too great, and therefore the velocities are a little too small; but the quantities discharged will be found about one-third too great, without affecting the velocities, on account of the convergency of the stream.

I	II	III	IV	V	VI
½	239	1·66	249	1·72	14
1	333	2·32	355	2·47	27

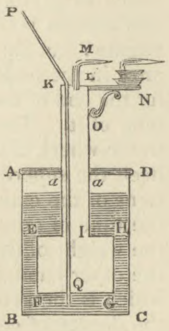
3	544	3·76	653	4·53	82
3½	582	4·03	715	4·98	95
4	611	4·24	774	5·38	109
4½	642	4·46	822	5·75	122
5	666	4·67	888	6·17	136
5½	693	4·84	950	6·49	150
6	711	5·06	997	6·92	163

This table extends far beyond the limits of ordinary use, very few blast-furnaces having a force exceeding 60 inches of water.

We shall conclude this account of blowing machines with a description of a small one for a blow-pipe. ABCD, (fig. 99) is a vessel containing water, about two feet deep. EFGH is the air-box of the blower open below, and having a pipe ILK rising up from it to a convenient height; an arm ON which grasps this pipe carries the lamp N: the blow-pipe LM comes from the top of the upright pipe. PKQ is the feeding-pipe reaching near to the bottom of the vessel.

Water being poured into the vessel below, and its cover being put on, which fits the upright pipe, and touches two studs *a*, *a*, projecting from it, blow in a quantity of air by the feeding pipe PQ; this expels the water from the air-box, and occasions a pressure which produces the blast through the blow-pipe M.

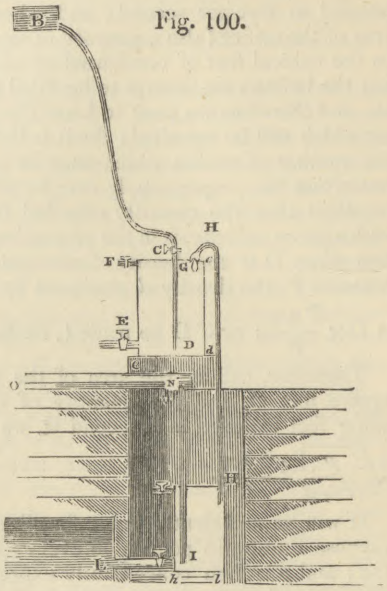
Fig. 99.



In a preceding part of this article, we mentioned an application which has been made of Hero's fountain, at Chemnitz in Hungary, for raising water from the bottom of a mine. We shall now give an account of this very ingenious contrivance.

In fig. 100, B represents the source of water elevated above the mouth of the pit 136 feet. From this there is led a pipe BCD, four inches diameter. This pipe enters the top of a copper cylinder *c d e*, 8½ feet high, five feet diameter, and two inches thick, and it reaches to within four inches of the bottom; it has a cock at C. This cylinder has a cock at F, and a very large one at E. From the top CF proceeds a pipe GHH′ two inches in diameter, which goes down the pit 96 feet, and is inserted into the top of another brass cylinder *fghi*, which is 6½ feet high, four feet diameter, and two inches thick, containing 83 cubic feet, which is very nearly one-half of the capacity of the other, viz. of 170 cubic feet. There is another pipe NI of four inches diameter, which rises from within four inches of the bottom of this lower cylinder, is soldered into its top, and rises to the trough NO, which carries off the water from the mouth of the pit. This lower cylinder communicates at the bottom with the water L which collects in the drains of the mine. A large cock K serves to admit or exclude this water; another cock M, at the top of this cylinder, communicates with the external air.

Fig. 100.



Now, suppose the cock C shut, and all the rest open; the upper cylinder will contain air, and the lower cylinder will be filled with water, because it is sunk so deep that its top is below the usual surface of the mine-waters. Now, shut the cocks F, E, M, K, and open the cock C. The water of the source B must run in by the orifice D, and rise in the upper cylinder, compressing the air above it and along the pipe GHH′, and thus acting on the surface of the water in the lower cylinder. It will therefore cause it to rise gradually in the pipe IN, where it will always be of such a height that its weight balances the elasticity of the compressed air. Suppose no issue given to the air from the upper cylinder, it would be compressed into one-fifth of its bulk by the column of 136 feet high; for a column of 34 feet nearly balances the ordinary elasticity of the air. Therefore, when there is an issue given to it through the pipe GHH′, it will drive the compressed air along this pipe, and it will expel water from the lower cylinder. When the upper cylinder is full of water, there will be 34 cubic feet of water expelled from the lower cylinder. If the pipe IN had been more than 136 feet long, the water would have risen 136 feet, being then in equilibrio with the water in the feeding pipe BCD, by the intervention of the elastic air; but no more water would have been expelled from the lower cylinder than what fills this pipe. But the pipe being only 96 feet high, the water will be thrown out at N with a very great velocity. If it were not for the great obstructions which water and air must meet with in their passage along pipes, it would issue at N with a velocity of more than 50 feet per second. It issues much more slowly, and at last the upper cylinder is full of water, and the water would enter the pipe GH and enter the lower cylinder, and without displacing the air in it, would rise through the discharging pipe IN, and run off to waste. To prevent this there hangs in the pipe HG a cork ball or double cone, by a brass wire which is guided by holes in two cross pieces in the pipe HG. When the upper cylinder is filled with water, this cork plugs up the orifice G, and no water is wasted; the influx at D now stops. But the lower cylinder contains compressed air, which would balance water in a discharging pipe 136 feet high, whereas IN is only 96. Therefore the water will continue to flow at N till the air has so far expanded as to balance only 96 feet of water, that is, till it occupies one-fourth of its ordinary bulk, that is, one-fourth of the capacity of the upper cylinder, or 42½ cubic feet. Therefore 42½ cubic feet will be expelled, and

Pneumatic engines.

the efflux at N will cease; and the lower cylinder is about one-half full of water. When the attending workman observes this, he shuts the cock C. He might have done this before, had he known when the orifice G was stopped; but no loss ensues from the delay. At the same time the attendant opens the cock E, the water issues with great violence, being pressed by the condensed air from the lower cylinder. It therefore issues with the sum of its own weight and of this compression. These gradually decrease together, by the efflux of the water and the expansion of the air; but this efflux stops before all the water has flowed out; for there is 42½ feet of the lower cylinder occupied by air. This quantity of water remains, therefore, in the upper cylinder nearly; the workman knows this, because the discharged water is received first of all into a vessel containing three-fourths of the capacity of the upper cylinder. Whenever this is filled, the attendant opens the cock E by a long rod which goes down the shaft; this allows the water of the mine to fill the lower cylinder, allows the air to get into the upper cylinder, and this allows the remaining water to run out of it. And thus every thing is brought into its first condition; and when the attendant sees no more water come out at E, he shuts the cock E and M, and opens the cock C, and the operation is repeated.

There is a very surprising appearance in the working of this engine. When the efflux at N has stopped, if the cock F be opened, the water and air rush out together with prodigious violence, and the drops of water are changed into hail or lumps of ice. It is a sight usually shown to strangers, who are desired to hold their hats to receive the blast of air: the ice comes out with such violence as frequently to pierce the hat like a pistol bullet. This rapid congelation is a remarkable instance of the general fact, that air by suddenly expanding, generates cold, its capacity for heat being increased. Thus the peasant cools his broth by blowing over the spoon, even from warm lungs; a stream of air from a pipe is always cooling.

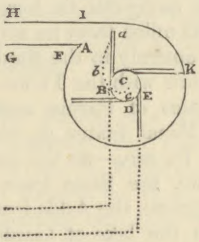
The above account of the procedure in working this engine shows that the efflux both at N and E becomes very slow near the end. It is found convenient therefore not to wait for the complete discharges, but to turn the cocks when about 30 cubic feet of water have been discharged at N: more work is done in this way. A gentleman of great accuracy and knowledge of these subjects took the trouble, at our desire, of noticing particularly the performance of the machine. He observed that each stroke, as it may be called, took up about three minutes and one-eighth; and that 32 cubic feet of water were discharged at N, and 66 were expended at E. The expense, therefore, is 66 feet of water falling 136 feet, and the performance is 32 raised 96, and they are in the proportion of 66×136 to 32×96, or of 1 to 0·3422, or nearly as 3 to 1. This is superior to the performance of the most perfect undershot mill, even when all friction and irregular obstructions are neglected, and is not much inferior to any overshot pump-mill that has yet been erected. When we reflect on the great obstructions which water meets with in its passage through long pipes, we may be assured that, by doubling the size of the feeder and discharger, the performance of the machine will be greatly improved; we do not hesitate to say, that it would be increased one-third: it is true that it will expend more water, but this will not be nearly in the same proportion, for most of the deficiency of the machine arises from the needless velocity of the first efflux at N. The discharging pipe ought to be 110 feet high, and not give sensibly less water. Then it must be considered how inferior in original expense this simple machine must be to a mill of any kind which would raise 10 cubic feet 96 feet high in a minute, and how small the repairs on it need be, when compared with a mill. And, lastly, let it be noticed, that such a machine can be used where no mill whatever can be put in motion. A small stream of water, which would not move any kind of wheel, will here raise one-third of its own quantity to the same height, working as fast as it is supplied.

For all these reasons, we think that the Hungarian machine eminently deserves the attention of mathematicians and engineers, to bring it to its utmost perfection, and into general use. There are situations where this kind of machine may be very useful. Thus, where the tide rises 17 feet, it may be used for compressing air to seven-eighths of its bulk; and a pipe leading from a very large vessel inverted in it, may be used for raising the water from a vessel of one-eighth of its capacity 17 feet high; or if this vessel has only one-tenth of the capacity of the large one set in the tide-way, two pipes may be led from it, one into the small vessel and the other into an equal vessel 16 feet higher, which receives the water from the first. Thus one-sixteenth of the water may be raised 34 feet, and a smaller quantity to a still greater height, and this with a kind of power that can hardly be applied in any other way. Machines of this kind are described by Schottus, Sturmius, Leupold, and other old writers; and they should not be forgotten, because opportunities may offer of making them highly useful. A gentleman's house in the country may thus be supplied with water by a machine that will cost little, and hardly go out of repair.

The last pneumatical engine which we shall speak of at present is the common fanners, used for winnowing grain, and for drawing air out of a room; and we have but few observations to make on them.

The wings of the fanners are enclosed in a cylinder or drum, whose circular sides have a large opening BDE, (fig. 101), round the centre, to admit the air. By turning the wings rapidly round, the air is hurried round along with them, and thus acquires a centrifugal tendency, by which it presses strongly on the outer rim of the drum: this is gradually detached from the circle as at KI, and terminated in a trunk IHGF, which goes off in a tangential direction; the air therefore is driven along this passage.

Fig. 101.



If the wings were disposed in planes passing through the axis C, the compression of the air by the anterior surface would give it some tendency to escape in every direction, and would obstruct in some degree the arrival of more air through the side holes. They are therefore reclined a little backward, as represented in the figure. It may be shown that their best form would be that of a hyperbolic spiral *a b c*; but the straight form approaches sufficiently near to the most perfect shape.

Much labour is lost, however, in carrying the air round those parts of the drum where it cannot escape. The fanners would either draw or discharge almost twice as much air if an opening were made all round one side. This could be gradually contracted, where required for winnowing, by a surrounding cone, and thus directed against the falling grain; as has been verified by actual trial. When used for drawing air out of a room for ventilation, it would be much better to remove the outer side of the drum entirely, and let the air fly freely off on all sides; but the flat sides are necessary, in order to prevent the air from arriving at the fanners any other way but through the central holes, to which trunks should be fitted leading to the apartment which is to be ventilated.

(J. R.)

PO, the largest river in Italy, called by the ancients *Padus* or *Eridanus*, rises on the E. side of Monte Viso, one of the highest summits of the Alps, between Italy and France; N. Lat. 44. 40., E. Long. 7. At first a mere mountain torrent, it flows eastward down the deep Val d'Oro; and being augmented by other streams like itself, turns to the left, and sweeps round the northern edge of the Monferrato hills. After describing nearly a semicircle, it emerges at Valenza into the broad plain of Lombardy, through which it flows eastward to the Adriatic, fed by the rivers that flow on the one side from the Alps and on the other from the Apennines. Its great volume, supplied from the everlasting snows of the Alps, renders the country liable to those destructive floods which have furnished the Latin poets with some of their finest comparisons. From Piacenza downwards, the river is confined by artificial embankments of very ancient origin; but these do not always prevent the danger. The constant deposits of soil tend to raise the bed of the stream above the surrounding country, so that at Ferrara the Po is on a level with the tops of the houses. For the last 200 miles of its course the breadth of the river varies from 400 to 600 yards, and the depth from 2 to 6 fathoms. Near its mouth it divides itself into two arms, each falling into the sea by several mouths, one belonging to each arm being accessible to small ships. Formerly the Po followed a different course to the sea, south of Ferrara, and its old channel is now filled partly by canals from the main river, and partly by the Reno from the Apennines. Considerable changes seem to have taken place on the coast-line, from the gradual deposit of sand and mud by the river; and indeed the whole lower part of the Lombard plain seems to have been gradually formed in this way. But these processes must have been accomplished for the most part ages before the historic period. The whole length of the Po is estimated at 420 miles; and it is navigable for barges and river steamers to a distance of 60 miles from its source. The upper part of its course lies entirely in the Sardinian territories; but after its confluence with the Ticino it separates Austrian Italy from the duchies of Parma and Modena on the north, and from the Papal States on the south. The principal affluents of the Po are,—on the north, the Dora Baltea from Mont Blanc, the Sesia from Monte Rosa, the Ticino from lake Maggiore, the Adda from the lake of Como, and the Mincio from the lake of Garda; and on the south, the Tanaro in Piedmont, the Trebbia and Taro in Parma, and the Secchia in Modena. The Po abounds in fish of various kinds, especially shad, salmon, and sturgeon. It imparts great fertility to the adjacent country. The free navigation of the Po is secured by a treaty concluded between Austria, Parma, and Modena in July 1850.

POCHETTI. See BARBATELLI.

POCKLINGTON, a town of England, in the E. Riding of Yorkshire, 12 miles E.S.E. of York, and 212 N. by W. of London. It stands in a flat region, near the western edge of the Yorkshire wolds, and is a pretty, well-built town, with a convenient market-place. Near the centre stands the plain old church, in the form of a cross, with a fine tower rising from its W. end. The town has churches for Dissenters, several schools, a literary institute, and a temperance hall. There are no manufactures here, the people being mostly engaged in farming; but some trade is carried on in cattle, corn, flour, timber, coal, &c. Pop. (1851) 2546.

POCOCK, **EDWARD**, a learned English divine, and the first oriental scholar of his time, was the eldest son of Edward Pocock, and born in November 1604, at Oxford, where he was also educated. In 1628 he was admitted probationer-fellow of his college; and about the same time he had prepared an edition of the second Epistle of St Peter, the second and third of St John, and the Epistle of St Jude, in Syriac and Greek, with a Latin translation and notes. In 1629 he was ordained priest, and appointed chaplain to the English merchants at Aleppo, where he arrived in October 1630, and continued for five or six years, during which he distinguished himself by his zeal and fortitude, particularly whilst the plague raged there in 1634. At length returning to England, he was in 1639 appointed reader of the Arabic Lectures founded by Archbishop Laud. Three years afterwards he went to Constantinople, where he prosecuted his studies of the eastern tongues, and procured many valuable manuscripts. After a residence of nearly four years in that city, he embarked in 1640; and taking Paris in his way, visited Gabriel Sionita, the famous Maronite, and also Hugo Grotius. In 1643 he was presented to the rectory of Childrey in Berkshire; and about three years afterwards married the daughter of Mr Thomas Burdett. About the middle of 1647 he obtained the restitution of the salary of his Arabic Lecture, which had been detained from him about three years. In 1648 Charles I., being then a prisoner in the Isle of Wight, nominated Pocock to the professorship of Hebrew, and the canonry of Christ Church annexed to it; but in 1650 he was ejected from his canonry for refusing to take the engagement, and soon afterwards a vote passed for depriving him of his Hebrew and Arabic professorships. But several governors of houses, and others, having presented a petition in his favour, he was suffered to enjoy both these places. He had some years before published his *Specimen Historiæ Arabum*, a very learned work, and now appeared his *Porta Mosis;* and soon afterwards the English polyglot edition of the Bible, to which he had largely contributed, and also Eutychius' *Annals*, with a Latin version, gave evidence of his industry and learning. At the Restoration he was reinstated in the canonry of Christ Church, and also received the degree of Doctor of Divinity. He then published his Arabic version of Grotius' *Treatise of the Truth of the Christian Religion;* and an Arabic poem entitled *Carmen Abu-Ismaelis Tograi*, with a Latin translation and notes. Soon afterwards he published Gregory Abulfaragius' *Historia Dynastiarum;* but this work did not meet with much encouragement from the public, a circumstance which his biographer accounts for in a manner not very creditable to the reign of Charles II. as compared with the Protectorate, when solid learning was appreciated and rewarded. The fact seems to be, that the love of Arabic learning was now growing cold; and Pocock himself, in his correspondence with Greaves, appears to be not only sensible that such was the case, but very much hurt by the decline of sound literary taste. The same circumstance also may in some measure account for this distinguished scholar not having obtained higher preferment at the period of the Restoration, when such numbers of vacant dignities were conferred on far inferior men. Perhaps he was almost the only instance of a clergyman, then at the highest pitch of eminence for learning and every other merit proper to his profession, who lived throughout the reign of Charles II. without the least regard from the court, except the favour sometimes done him of being called upon to translate Arabic letters from the princes of the Levant, or the credentials of ambassadors coming from thence; a service for which we do not find that he obtained any recompense besides fair words and hollow compliments. But his modesty equalled his merit; and after presenting Abulfaragius to the king, he ceased to obtrude his claims on the attention of royalty. In 1674 he published an Arabic version of the principal parts of the Liturgy of the Church of England; and a few years afterwards appeared his *Commentary on the Prophecies of Micah, Malachi, Hosea, and Joel.* This truly great man died in 1691, after having been for many years confessedly the first orientalist in Europe; and he was no less worthy of admiration for his uncommon modesty and humility, and all the virtues which can adorn a Christian. His theological works were republished at London in 1740, in 2 vols. folio, by Leonard Twells, M.A., with some account of his life and writings.

Pocock's son Edward published the works of Ibn Tofayl, the same which Ockley afterwards translated into English. He translated also the work of Abn-l-latif on Egypt, published for the first time at Oxford in 1800. Another of Pocock's sons translated into English the *De Termino Vitæ* of Manasses Ben Israel, London, 1699.

POCOCKE, RICHARD, distantly related to the preceding, was the son of Mr Richard Pococke, head master of the free school at Southampton, where he was born in the year 1704. He received his school learning under his father, and his academical education at Corpus Christi College, Oxford, where he took his various degrees. He commenced his travels in the East in 1737, and returned in 1742. In 1743 he published his *Observations on Egypt*, under the general title of *A Description of the East and some other Countries*. In 1744 he was made precentor of Waterford; and in 1745 he printed the second volume of his Travels, under the title of *Observations on Palestine, or the Holy Land, Syria, Mesopotamia, Cyprus, and Candia*, which he dedicated to the Earl of Chesterfield, then lord-lieutenant of Ireland, whom he attended in the capacity of domestic chaplain. In 1756 Dr Pococke was promoted to the bishopric of Ossory, vacant by the death of Dr Edward Maurice; in July 1765 he was translated to the see of Meath, which had been originally intended for the Bishop of Elphin, who, however, declined taking out his patent; and he died suddenly in September following, having been carried off by apoplexy, whilst engaged in visiting his diocese. As a traveller, Dr Pococke was equally distinguished for research, learning, and accuracy, to which ample justice has indeed been done by Jablonski, in the Preface to part third of his *Pantheon Ægyptiorum*. He penetrated farther up the Nile than the island of Philæ, called by the Arabs the Temple Island; whereas Norden, in 1737, proceeded as far as Derré, between the first and second cataracts. The two travellers are supposed to have met on the Nile, in the neighbourhood of Esneh, in January 1738; but, according to another account, they passed in the night without recognition.

Bishop Pococke visited other parts besides the East, and described some remarkable objects both in Scotland and Ireland. A French translation of his Travels appeared at Paris, 1771, in 7 vols. 12mo.

PODGORITZA, a town of European Turkey, in Albania, near the frontier of Montenegro, 38 miles N. of Scutari. It stands at the confluence of the rivers Moratsha and Chicuna, the latter of which is here crossed by a long wooden bridge. A short distance to the north lie the ruins of the ancient *Dioclea*, now called Dickla. They consist of temples, palaces, and isolated pillars; but they are gradually diminishing, as the people of Podgoritza make free use of the remains for building materials. Pop. 6000.

PODOLIA, or **PODOLSK**, a government of European Russia, lying between N. Lat. 47. 25. and 49. 45., E. Long. 26. 20. and 30. 55.; and bounded on the N. by the governments of Volhynia and Kiev, E. by that of Kherson, S. by those of Kherson and Bessarabia, and W. by the Austrian province of Galicia; length, from N.E. to S.W., 240 miles; greatest breadth, 80 miles; area, 16,449 square miles. The surface is generally level, slightly sloping from the Carpathians towards the S.E.; and a chain of hills, scarcely rising 500 feet above the sea, extends in that direction between the Dniester and the Bug. These two are the principal rivers of Podolia, and, with their affluents, water the entire country. The former only bounds the government on the S.W.; and the latter, rising on its northern confines, flows through it in a S.E. direction. The south-eastern part of the government is occupied with flat and sandy steppes. There are no lakes of any size in the country. Podolia enjoys a salubrious climate, an exceedingly rich soil, and contains much picturesque scenery. The principal mineral products are, saltpetre, lime, building-stone, and alabaster. Vines and mulberries grow here in the open air. Besides corn, the crops chiefly raised in the government are hemp, flax, hops, and tobacco. There are wide and rich meadows and pastures, on which large herds of excellent cattle are raised. A great part of the country is likewise occupied with forests, which produce excellent timber for ship-building. The extent of arable land in Podolia in 1849 was 5,577,736 acres; of meadow-land, 1,276,508 acres; of wood, 1,145,824 acres; and of waste land, 1,104,997 acres. The quantity of corn raised in the same year was 34,394,675 bushels; and that of potatoes, 2,454,880 bushels. The government contained in that year 96,436 horses, 353,864 horned cattle, 664,107 sheep, 160,086 swine, and 9933 goats. Hares, wolves, foxes, bustards, and other wild animals are found in Podolia; and the rivers are well supplied with fish. There is little manufacturing industry in the government; it contained, however, in 1849, in all 186 manufactories of various kinds, employing 2811 hands. Among the former, there were 10 tanneries, 15 manufactories of tobacco, 18 of tallow and candles, 85 of cloth, 12 of tiles, and 22 of beet-root sugar. The trade of the country, almost entirely carried on by Jews, consists mainly in exportation of corn to Odessa, and of cattle to Galicia. Most of the people belong to the Greek Church; but there are considerable numbers of Roman Catholics and of Jews, and a few Protestants and Mohammedans. The educational interests of the government are under the control of the university of Kiev; but they are in a low condition; and there are few schools in the country. Podolia is divided into twelve circles. The capital of the government is Kamenez Podolsk. Like the other governments in West Russia, Podolia once belonged to Poland, but has formed since 1772 a part of the Russian empire. Pop. (1851) 1,577,966.

POE, EDGAR ALLAN, author of the *Raven*, was born at Baltimore in the United States, in January 1811. His father, David Poe, while a student of law at Baltimore, had become enamoured of Elizabeth Arnold, an English actress, with whom he eloped. He married her, gave up his studies, and took to the stage. After a few years, they both died, leaving behind them three children in a state of utter destitution. The eldest, Edgar, a child of remarkable beauty and precocious wit, was then about six years old; and a Mr John Allan, a wealthy merchant, adopted him. In 1816 he visited Great Britain in company with Mr and Mrs Allan, and subsequently passed from four to five years with the Rev. Dr Barnsby, in a school kept at Stoke-Newington, near London. On his return to the United States he entered the university at Charlottesville, and there gave evidence of feats of hardihood, reckless wildness, and considerable genius. Gambling and intemperance induced his expulsion from the university. He quitted the place much in debt; and on Allan's refusal to accept some of the drafts, he wrote him an abusive letter, quitted the place, and sailed for Greece, then engaged in a struggle with the Turks. We know but little of his adventures for a year; at the end of which time he broke in upon the slumbers of the American minister in St Petersburg, to save him from penalties incurred in a drunken debauch. Through the ambassador's intercession, he was enabled to return to the United States. He became a cadet in the military academy, and, after passing ten months there, he was cashiered for dissipation and neglect of duty. He returned to Allan, who was still disposed to treat him as a son; but owing to a quarrel with the future Mrs Allan, he and his patron parted for ever. He published a small volume of verses, enlisted as a private soldier, was recognised by officers at the military academy, who were forming measures for his release, with prospects of success, when it was discovered that he had deserted. Two prizes were now offered by the proprietor of the *Baltimore Saturday Visitor* for the best tale and poem suited to his magazine. Poe competed, and was successful. This award was published 12th October 1833. He obtained, through the exertions of this committee, the editorship of a magazine published at Richmond, Virginia; but after the lapse of a few months, he fell into a state of brutish drunkenness, which resulted in his dismissal. While at Richmond, in January 1837, he had married his cousin, Virginia Clemm, a very amiable and lovely girl, who was as poor as himself. He went from Richmond to Baltimore, from Baltimore to Philadelphia, and from Philadelphia to New York. Towards the end of 1838 he settled in Philadelphia, and became editor of a magazine which Burton the comedian had recently established. Here he stayed for more than a year: his works were appreciated; his fame was increasing; when, before the summer was over, he relapsed into his former habits, and was for weeks regardless of everything. This led to his dismissal. Some months afterwards he became editor of *Graham's Magazine*. His connection with this periodical, which continued about a year and a half, was one of the most active and brilliant periods of his literary life. He wrote for it some of his finest tales and most charming criticisms. During his residence at Philadelphia his manner was usually very quiet and gentlemanly; he was generally dressed with simplicity and elegance; and there was a singular neatness and air of refinement about his home. For this he was mainly indebted to his mother-in-law, who loved him with more than maternal devotion and constancy. In 1844 he removed to New York, where he was received into circles accustomed to the appreciation as well as to the production of literature. It was here, during the outset of his career, that he published his poem of the *Raven*, of which Mr Willis justly observed, "It is the most effective single example of fugitive poetry ever published in America." His reputation as a magazinist rose rapidly; and his tales and critical articles set him on the high road to fame. In 1846 Poe's constancy again gave way, and he was reduced to quite an alarming destitution. He was ill; his wife was dying; and his mother-in-law, with his manuscript in her hand, was wandering the streets of New York. In 1848 he advertised several lectures, with the view of obtaining money to start a long-contemplated monthly journal. They were subsequently published as *Eureka, a Prose Poem*, on the cosmogony of the universe, to the composition of which he brought his subtlest and highest gifts in their fullest power. From this period Poe did not write much; he had quarrelled with most of the chief magazines for which he had formerly written. His name was associated about this time with one of the most brilliant women of New England; and he has immortalized her by the poem, "I saw thee once—once only—years ago." They were not married, however; and the breaking of the engagement seems entirely owing to his own wilful caprice. After a temporary absence from New York in the autumn of 1849, he arrived in Baltimore. He met acquaintances who induced him to drink, and, after a night of insanity and exposure, he was borne to an hospital, where he died the same evening at the age of thirty-eight.

In person, Poe was below the middle height, slenderly but compactly formed, and in his better moments was gentlemanly in an eminent degree. His voice was modulated with astonishing skill, and his elocution was at times wellnigh supra-mortal. He was at all times a dreamer, dwelling in ideal realms peopled with the creatures and accidents of his brain. His harsh experience had apparently deprived him of all faith in man and woman. His poetry is characterized by great originality and sweetness. He was a master of rythm; and put nothing out of his hand that did not bear the stamp of his genius. He wrote but little; but that little was in general of the highest mark. No American poet has reached the poetical heights which were familiar to Poe. His verses have all a dreamy, unworldly grandeur about them; sufficiently real to awaken an interest in the reader, and sufficiently ideal to carry him beyond himself and the things of sense and time. For a perfect mastery over language, and that subtle harmony which constitutes the very highest music, Poe knew but few equals. His versification was liquid and musical; and his entire composition was constructed with the design of being as near perfection as possible. His prose tales are very much like his poetry; but with this difference, that in general he chooses for his poetry subjects fitted to awaken melancholy, or at most exquisite sorrow; while in his prose he harrows up to the foundation the very roots of one's nature, and seems to take a positive pleasure in the exercise. A number of his pieces, to be sure, mainly address themselves to our curiosity, without involving the reader in any fit of feverish anxiety; yet so masterly is this executed, that one might safely say, no one, of any measure of culture, began a story of Poe's without completing it with breathless interest. The style is so simple and yet so accurate, so smooth and yet so highly finished, that it is only on reflection that one perceives the charming vehicle on which he has been carried along. He had a most subtle and delicate intellect, and an imagination singularly weird and unworldly. His works, and especially his poems, were more or less a reflection of his life. He wrote with fastidious difficulty, and in a style too high to be well paid. His works have been published in 4 vols., 1857.

POELEMBURG, Cornelius, an eminent Dutch landscape-painter, was born at Utrecht in 1586, and after receiving the first principles of his art from Bloemart, repaired to Rome to study the works of Raphael. He formed in course of time a style of his own. His custom was, to represent on a small canvas, with a light and delicate touch, a well-selected landscape. Neat figures and imposing ruins were introduced to add to the picturesque effect. The whole scene was finished with a delicate colouring which equalled the suavity of enamel. This artistic excellence soon introduced Poelemburg to a brilliant career of popularity. During a residence of several years at Rome, his studio was the resort of cardinals and other dignitaries. On his way home, the Grand Duke of Florence would fain have retained him at court. After his return to Utrecht, he was summoned in 1637 to England to paint for Charles I. and the nobility. Nor did prosperity desert him when he sought again his native city. He continued to amass a large fortune, and to see his pictures imitated by many rising artists, till his death in 1660. The pictures of Poelemburg are scarce. Many of his figures may be seen in the landscapes of Claude, Jan Both, and Kiering.

POETRY.

Definition.

The difficulty of giving a definition of poetry, which shall include all that essentially belongs to it, and exclude all that is foreign or accidental to it, has been long felt and admitted. The definition of the ancients, which makes poetry "an imitative art," is obviously exposed to the double objection of being at once too comprehensive, since it would equally apply to the other imitative arts of painting and sculpture; and too limited, since it would exclude many departments of poetry, in which, as in the lyrical, the art is not properly *imitative*, but *expressive;* not copying in any sense the thoughts and actions of others, but presenting to the sympathy of the reader the emotions of the poet himself. Not less objectionable is the definition, that poetry is "the art of expressing our thoughts by fiction;" which, while it is equally applicable to the novel and the romance, is, in fact, not necessarily true of poetry at all, except in this sense, that in all high poetry a certain transforming and beautifying power of imagination is excited, which in some measure transmutes the forms of things from their actual prosaic aspect,

> Clothing the palpable and the familiar
> With golden exhalations of the dawn.

Still less can verse or metrical form be regarded as constituting the essence, or even one of the essentials, of poetry. It no doubt heightens its effect; it increases its charm and power of pleasing, by enlisting the aid of musical sound and cadence on the side of imaginative language or touching sentiment; but it must yet be regarded as amongst the externals of poetry,—something which will never make poetry of itself, and without which poetry is not only conceivable, but has in fact existed, and that in very striking and impressive forms.

Object of poetry the communication of intellectual pleasure.

Poetry may perhaps be defined to be an art which has creation of intellectual pleasure for its object, which attains its end by the use of language natural in an excited state of the imagination and the feelings, and generally, though not necessarily, formed into regular numbers. The proper antithesis, therefore, to poetry, as Mr Coleridge has remarked, is not prose, but science. The proper antithesis to prose is verse. Science seeks to instruct, to discover and to communicate truth; "the proper and immediate object of poetry is the communication of immediate pleasure." Poetry may indeed incidentally instruct, as science may indirectly communicate pleasure; but the object of each must be gathered from its main direction and bearing, and in this sense the production of intellectual *enjoyment* is unquestionably the aim and the proper province of poetry.

This a pleasure conducive to morality.

But so closely are the intellectual and refined pleasures of man connected with his moral qualities; so much does his relish for the higher and more spiritual pleasures of the imagination depend on a sound and healthy state of morality in the first instance, and so much is this state in turn promoted and encouraged by stimulating and keeping alive the activity of the imagination and the sensibilities of the heart, that poetry, though generally avoiding the form of direct instruction, may yet be said, with justice, to be the most important handmaid and assistant of moral education, by its appeals to those affections which are apt to become indolent and dormant amidst the commerce of the world, and the revival of those purer and more enthusiastic feelings which are associated with the earlier and least selfish period of our existence. Immersed in business, which, if it sharpen the edge of intellect, leaves the heart barren; toiling after material wealth or power, or struggling with fortune for existence; seeing selfishness reflected all around us from the hard and glittering surface of society, as from a cold and polished mirror; it would go hard with man in adversity, perhaps still more in prosperity, if some resource were not provided for him, which, under the form of an amusement and a recreation, administered a secret but powerful balm in the one case, and an antidote in the other. This resource is afforded us by the influences of poetry. "Whatever withdraws us from the power of the senses; whatever makes the past, the distant, and the future, predominate over the present, advances us in the dignity of human beings." Sometimes, no doubt, poetry openly assumes the garb of morality, but it is generally least instructive when most directly *didactic*, and practically attains the end of instruction with most success when the instructor is himself unconscious of the lesson he conveys. In an indirect form, however, and through the medium of the feelings and the imagination rather than the mere reason, its efficiency as a moral agent is great and undeniable. And as upon the intellectual worth and nobleness of individuals depends the standard of a national morality, it may with truth be said that the fame and character of nations,—those qualities the presence of which makes the smallest state conspicuous in the world's eye, and the absence of which renders the widest empire, on which the sun never sets, insignificant; namely, national pride, honour, fidelity to engagements, courage to act, fortitude to suffer, a generous and far-seeing policy, disdaining all mean or questionable advantages; are to some extent derived, and, at all events, continually cherished and fostered, by the influence of a pure and ennobling national poetry. If Plato had succeeded in banishing poets from his ideal republic, he would assuredly have conferred no benefit upon morals. He would have created a hard and utilitarian frame of society, inaccessible to generous feeling, and incapable of those great efforts, either of action or of endurance, which have their source only in enthusiasm, and cannot be suggested by any principle of expediency, however enlarged may be the basis of calculation.

No poetry permanently popular which is of an immoral nature.

It is the conviction of this intimate though indirect connection between poetry and morality, and the consequent bearing of the former upon human welfare, that explains the veneration which mankind have always felt for those poets who, acting under an impression of the sacredness of the task committed to them, and of the power of the talisman which genius has placed in their hands, have devoted their labours to the purest forms of poetry, and to the excitement of emotions, either virtuous in themselves, or conducive to virtue. It is this conviction which accounts for the aversion which they have never failed in the end to manifest against all those who have made the fascinations of poetry and wit subservient to the gratification of baser feelings or meaner propensities. For men taken in the mass judge rightly, even when they act wrongly; and moral opinion, so variable and wavering when applied to our own case or that of our friends, is found a safe and steady guide when applied to the mere *representation* of human thought and action in the forms with which they are invested by the poet. Hence the feelings of all men are enlisted and warmly excited on the side of virtue in fictitious composition, and still more in the most fascinating form of fictitious composition, poetry. For here the *tendency* of the poem is felt to be no mere speculative question, but a real dispute "pro aris et focis;" a contest whether, as is said to be often the case in India, poison is to be conveyed into the wells from which pure and refreshing water ought to be drawn. And this practical bearing upon important interests, of the abuse of a fine art, is more felt, and justly, in poetry than in any other. In painting, for instance, Parrhasius, Julio Romano, Annibal Caracci, and Titian, have ministered by their pictures to the promotion of vice; in sculpture, some have even endeavoured to pervert the pure marble into a vehicle of impure representations; but the circle of their operation is limited; to the mass of men their iniquities of this nature are even unknown: but poetry, multiplied indefinitely by printing, finding its way into every quarter of the globe, and penetrating into the humblest as well as the highest class of society, has a sphere of operation bounded only by the globe itself, and a practical influence, through their sympathies, upon men's habits of thought, and consequently upon their morality and their happiness, which is not the less certain and extensive, that its limits do not admit of any precise or distinct determination.

Hence it is a remarkable fact in the history of poetry, that no work essentially immoral, or even exhibiting a manifest indifference to moral feeling, has ever maintained a permanent popularity. The low ribaldry which deforms the splendid talents of Aristophanes will always render the perusal of his plays a painful task; the witty licentiousness of the Pucelle is already all but forgotten; and the next generation, while they treasure the better parts of Byron, will assuredly consign to oblivion much of his gloomy reasonings, his contempt for human nature, and his ridicule of generous feelings. The poets who are found to retain their hold over all hearts, and whose influence even appears to extend with the progress of ages, Homer, Shakspeare, Milton, Spenser, Calderon, Tasso, are those who have done their utmost to elevate rather than to depress the spirit and the hopes of men; to make existence brighter about us, and to embody in their strains the principles of faith and hope, of purity and universal charity. For it need hardly be observed, that we are not to condemn a work as immoral on account of a few brief passages, in which the poet, led away by a too lively imagination, has admitted scenes or images of an objectionable kind. Such, indeed, are to be found in Shakspeare, and in the pure and religious poems of Spenser; more rarely also in Tasso; but the general strain of the poem, and the obvious aim of the poet, being to promote the cause of virtue, the few objectionable particulars are lost in the general effect, and cease to be dangerous from their proximity to so much that is calculated to purify and to elevate the mind.

Painting and poetry; qualities common to both.

If it be difficult to give an accurate definition of poetry, it is still more difficult to describe the precise combination of the mental and moral qualities which are required for its production, so as to distinguish these from the qualities requisite for perfection in the other imitative arts. The sensibility to natural and moral beauty; the study both of the outward world and of the mind of man; imagination and fancy to furnish the materials; judgment and taste to select and arrange them; these are common to the great poet and the great painter. What determines these energies and capabilities to the one direction more than to the other, and makes one man paint to the bodily eye in colours, the other to the eye of the mind in words, is that secret undefinable instinct which we call genius, which it is impossible to resolve into any mere result of the force of circumstances, and which, all experience teaches us, is born with the artist, and, like an instinct, directs his after-course. A genius for poetry or for painting is as certainly dependent on an organization mental and physical, with which we come into the world, as a musical ear; no education can give them; no general superiority of intellect will enable a man to turn with equal success to either; nature made him with the elements of a poet or a painter, and what she has so framed, art and education will never alter.

But though it is difficult to enumerate any quality requisite to form a great poet which is not necessary also to form a great painter, it is easy to see, that from the nature of the materials with which they deal, as well as their modes of operation; the one producing its effects by a momentary impression, the other by a continuous exertion; the degree in which the different component qualities of mind are employed in these respective arts is materially different.

Imagination.

Foremost amongst the qualities that constitute the poet is imagination, that creative principle of the mind which forms new conceptions out of previously existing materials; "conceptions not absolutely justifiable by the rules of logic, but quite intelligible to the mind when duly elevated; intelligible through our sympathies or sensibilities, though not sufficiently definite nor strictly coherent to stand the cold survey of our reason." This is indeed the most essential gift of the poet, "where either he must live or have no life;" with it, he may triumph over every other defect; without it, no combination of qualities will ever render him a great poet. This is the power which emancipates the poet from the trammels of space and time; carries him back into the spirit of past ages; enables him to create and to endow with coherent attributes beings of a nature different from our own, and yet having for us a real existence, so far as our sympathies are concerned: to conceive and consistently to follow out the thoughts, and words, and passions of imaginary actors, and all this not by a metaphysical analysis of the emotions or passions, nor by a course of induction from actual observation in the world about him, but by a secret consciousness, flashing upon his mind, in a concentrated shape, the result of all philosophy, embodying all which conception, abstraction, and judgment would have separately furnished. It supersedes the necessity of observation in every special case, because it furnishes him with those primary elements of our nature which give the formula for the solution of all. The value of patient observation and study of life and character, in addition to the suggestions of the imagination, we do not dispute; we shall afterwards see, that within certain limits, and for certain departments of poetry, they are indispensable. But we may be assured, that for those elemental conceptions of character which are unmodified by mere manners, local position, or age; the conception, for instance, of a Lear or a Miranda, a Caliban, an Ariel, or a Hamlet; no observation of human character in the actual world, nor dissection of the component passions and sympathies that make up character, would have sufficed. We have but to look at the range of Shakspeare's characters to be at once satisfied of this. Pre-eminent amongst these are his characters of women; and yet from what analysis of character, or observation of society, could these have been drawn? Where could a youth, whose chief companions had been deer-stalkers, actors, or play-writers of no high repute, and to whom female society, at least in its most refined form, must have been unknown, have gleaned the materials which enable him to pourtray, with equal mastery, the fierce overbearing spirit of Lady Macbeth and Constance, the tranquil regal dignity of Hermione and Katharine of Aragon, or the totally dissimilar aspect of female character presented in the passion of Juliet, the purity of Miranda, the simplicity of Ophelia, or the tender submission and wife-like confidence of Imogen and Desdemona? No prototypes existed in the society around him from which these could be drawn. The streets and taverns of London might indeed furnish him with Bardolphs and Pistols; his acquaintance with Lord Southampton, or with the other gallants of the court, might afford the outlines of his Prince Henry or Hotspur; but his female creations are obviously drawn from no other sphere but his own breast. They are the offspring of an imagination "all compact," not elaborately constructing, but almost unconsciously creating.

The power of imagination is shown in its most imposing form in the conception of character, incident, situation, and scenery,—in the general scope and design of the poem; but its value and importance as an element of poetry is scarcely less felt in the details, in the manner in which it informs and transforms the whole language of the poem; studding it with imagery, simple or complex, often making a single word act like a spell, and conjure up a host of magical associations. Its province in this respect is not to be confounded with that lower department of the poetical art which is called diction, and which, when the idea is formed, simply dictates the selection of the *word* most appropriate to express the precise *idea* to be conveyed. Imagination supplies the idea itself, or fasciculus of ideas, to be embodied in the word; and in the number, novelty, and judicious selection of associations which can be suggested to the mind within any equal space, lies the chief difference between the work of a great poet and an inferior one, between an original or an imitative mind.

The images suggested by the imagination, we have said, are frequently complex. It seems to fuse many in one, to divide one into many, and to present the mass to the mind in a form which suggests all the particulars of which it is composed. It is certain, too, that many of the images which it suggests, and the effect of which upon the mind is immediately felt by all lovers of poetry to be beautiful, can by no means be justified upon the principles of logic, or their coherence made clear to the understanding. " When Milton tells us of ' darkness visible,' " says a writer on poetry, " we feel that he has uttered a fine paradox; we *feel* its truth, but cannot prove it. And when in that appalling passage where the poet stands face to face with Night and Chaos in their dark pavilion, ' spread wide on the wasteful deep,' and says that

By them *stood*
Orcus and Ades, and the dreaded *name*
Of Demogorgon,

how is it possible to reconcile such expressions to a mere prosaic understanding? Darkness is, strictly speaking, absence of light. How then shall we say that it is visible, when we see only by the aid of light? And with respect to the ' *name*' of Demogorgon, which *stands* by Orcus and Ades, how can such a phrase be justified by the rules of reason? Nevertheless it is as magnificent as words can make it. It is clothed in a dark and spectral grandeur, and presses upon our apprehensions like a mighty dream."[1] Take another instance also from Milton, where he speaks of music

At every fall smoothing the raven down
Of darkness till it smiled.

Here also it is impossible to perceive the mere logical connection of the images; for, allowing darkness to be embodied under the notion of some bird with glossy and raven plumage, it would certainly puzzle any critic to show how musical sounds could smooth such plumage; and yet we should have little hesitation in putting this passage to any one as a test whether he possessed a feeling or sense of poetry, or whether his mind was entirely of a prosaic character. In these, and a thousand similar instances, particularly in Shakspeare, it is clear that the poetical effect can be explained upon no ordinary principle of reason. The metaphors are what are called broken; they cannot logically be united, and yet they have a sufficient poetical coherence. How this result is produced we shall only be enabled to explain when the whole laws which govern the faculty of imagination, as yet most imperfectly understood, shall be discovered.

It is somewhat difficult to establish a plain and practical distinction between fancy and imagination, so far as regards the imagery or ornaments of poetry; though, as we have already said, the higher efforts of conception, and the general design, fall almost entirely, in serious and heroic poetry, under the province of imagination. From Milton's line, " Sweetest Shakspeare, Fancy's child," it would seem that the words fancy and imagination had then been used as having the same meaning; for certainly any one now endeavouring to describe the most remarkable of Shakspeare's qualities would refer to his imagination rather than his fancy. Yet fancy may perhaps be said to be imagination at a lower point of excitement; not dealing with passions, or creating character; nor pouring out unconsciously, under the influence of strong feeling, images as they arise massed and clustered; but going in search of comparisons and illustrations, and when it invests them with personality, as in metaphors, still adhering much more closely to the logical fitness and sequence which govern similar ornaments in prose. It seems to act like a colder and weaker species of imagination, furnishing the thoughts which " play round the head, but do not touch the heart;" pleasing the eye and the ear; creating or heightening the idea of the beautiful, much more than of the sublime. It is not careful, like imagination, to make the whole bear on the general design, and heighten the main impression sought to be produced, but rather strives to excite our pleasure, and to bespeak our admiration for the images which it suggests. Its natural field, so far as regards the general design, is in poems like the Rape of the Lock, or the Lutrin, where the object is to give a poetical dress to a subject essentially prosaic, and excluding passion or high imagination. To these it lends an airy machinery, ingenious comparisons, imagery of a lively and pleasing cast in harmony with the level tone of the subject, and thus brings them within the domain of poetry. Some have represented the distinction between the effects of imagination and fancy to consist in this, " that the former altogether changes and remodels the original idea, impregnating it with something extraneous; the latter leaves it undisturbed, but associated with things to which, in some view or other, it bears a resemblance." But this distinction cannot be admitted; fancy, though in a less degree, does create, or change and remodel ideas; the difference between them must be sought more in the sort of ideas on which they operate, and the purposes to which they apply them, than in the plastic power supposed to be exercised in the one case and not in the other. " Fancy," says Mr Wordsworth, in a fine passage in his preface, " depends upon the rapidity and profusion with which she scatters her thoughts and images, trusting that their number, and the felicity with which they are linked together, will make amends for the want of individual value; or she prides herself upon the curious subtilty and the successful elaboration with which she can detect their lurking affinities. If she can win you over to her purpose, and impart to you her feelings, she cares not how mutable and transitory may be her influence, knowing that it will not be out of her power to resume it upon an apt occasion. But the imagination is conscious of an indestructible dominion; the soul may fall away from it, not being able to sustain its grandeur; but if once felt and acknowledged, by no act of any other faculty of the mind can it be relaxed, impaired, or diminished. Fancy is given to quicken and to beguile the temporal part of our nature, imagination to incite and support the eternal. Yet it is not the less true, that fancy, as she is an active, is also, under her own laws and in her own spirit, a creative faculty. In what manner fancy ambitiously aims at a rivalship with the imagination, and imagination stoops to work with the materials of fancy, might be illustrated from the compositions of all eloquent writers, whether in prose or verse, and chiefly from those of our own country. Scarcely a page of the impassioned parts of Bishop Taylor's works can be opened that shall not afford examples. Referring the reader to these inestimable volumes, we will content ourselves with placing a conceit, ascribed to Lord

---

[1] Edinburgh Review, 1825.

Chesterfield, in contrast with a passage from the Paradise Lost.

> The dews of the evening most carefully shun;
> They are tears of the sky for the loss of the sun.

After the transgression of Adam, Milton, with other appearances of sympathizing nature, thus marks the immediate consequence.

> Sky lowered, and, muttering thunder, some sad drops
> Wept at completion of the mortal sin.

The associating link is the very same in each instance; dew and rain, not distinguishable from the liquid substance of tears, are employed as indications of sorrow. A flash of surprise is the effect in the former case; a flash of surprise and nothing more; for the nature of things does not sustain the combination. In the latter, the effects of the act, of which there is this immediate consequence and visible sign, are so momentous, that the mind acknowledges the justice and reasonableness of the sympathy in nature so manifested; and the sky weeps drops of water, as if with human eyes, as earth had before trembled from her entrails, and nature given a second groan.” It is evident, that in the parallel passages thus opposed to each other by Wordsworth, the creative or remodelling operation produced by fancy in the former case, and by imagination in the latter, is the same; in both the sky is endowed with personality and human feeling; it is the propriety of the action attributed to the imaginary being in the one case, and its unreasonableness in the other, which makes the former merely fanciful, the latter highly imaginative.

Danger of an excess of fancy.

It will readily be perceived, from what has here been said of the nature of fancy, that when unregulated by a strong judgment, and unwarmed by strong passion, it is one of the most dangerous qualities which a poet can possess. To the predominance of this quality, indeed, to the consciousness of a facility of finding ingenious analogies or subtile distinctions, of conjuring up a multitude of fantastic resemblances, pleasing in themselves, but in no way heightening the leading impression sought to be conveyed, are to be ascribed many of the errors of taste by which modern poetry has been deformed. To this must be ascribed those conceits, from which scarcely a single Italian writer prior to the eighteenth century is free, and which reached their consummation in Marino; to this the similar extravagancies of Gongora, Quevedo, and their followers in Spain; the affected taste introduced by Voiture and Balzac in France, and exploded by the good sense of Molière; and the similar extravagancies of our own metaphysical poets. An excess of imagination cannot lead to bad taste in style; an excess of fancy is but too apt to produce that effect.

Judgment.

Of judgment, which is the regulating and controlling power by which the active and creative faculties of imagination and fancy are guided, checking the too daring flight of the one, and pruning the excesses of the other, it is needless to speak; since it is a quality not more peculiarly requisite in poetry than in oratory, or any of those departments of intellectual exertion which depend not on demonstration, but on the balance of probabilities. In fact, the highest range of imagination has invariably been found to be accompanied by a corresponding depth and comprehensiveness of judgment; or rather, perhaps, it would be more philosophical to say, that judgment is involved and constitutes one of the component parts of high imagination. For the imagination, as is justly remarked by Mr Stewart, is a *complex* power. “It includes conception or simple apprehension, which enables us to form a notion of those former objects of perception or knowledge, out of which we are to make a selection (in the fine arts); abstraction, which separates the selected materials from the qualities and circumstances which are connected with them in nature; and judgment or taste, which selects the materials, and directs their combination.” It is only in minds where imagination is limited, and where its possessor tries by effort and straining to enlarge it beyond its appointed bounds, that the judgment is generally found defective. Homer and Shakspeare, the most inventive and imaginative of poets, are also the most sagacious, the most practical, the most abounding in wisdom, both of a worldly and of a higher kind.

Study necessary to form a poet.

But, in addition to the natural gifts of sensibility to feel, memory to retain impressions, imagination and fancy to fashion new conceptions, and judgment to blend in harmony all the materials which have been thus accumulated, study is just as essential for the formation of the poet as for the acquisition and practice of the most mechanical art. That study regards both the materials of poetry and the language by which they are to be communicated in a sensible form to others. Study of men in the different conditions of life, and the habit of observing and systematising these observations; study of external nature, so as to mark the peculiarities which escape common eyes; the accustoming the mind to search for resemblances among things different, and to lay them up in the memory as in a treasury; these are assistances which no poet can overlook, and without which the imaginative faculty is deprived of its due nourishment, and of half its power. For even imagination does not strictly create out of nothing; it must be quickened and set in motion by something external, and demands materials on which it can try its processes of change or recombination. All great poets, therefore, have steadily pursued this course of study of nature, both moral and physical; though, after the habit is once formed, these mental operations are carried on almost unconsciously, and the treasures of poetical observation grow upon their possessor, without his being conscious of any effort in their accumulation. A remarkable instance of the attention paid by great poets to the minutest peculiarities of external nature, and of course equally applicable to the study of mental phenomena, is afforded by the case of Sir Walter Scott. Every one knows the graphic truth as well as the wonderful variety of his descriptions of scenery, which, by their selection of every thing that is characteristic, embody the very spirit of the place, and call back to our minds the impression with which we had first viewed it, and which had faded away and become forgotten. It is evident that in such descriptions Scott trusted little to the imagination, as able to compensate the observation of reality. Mr Morritt mentions, that whilst he was engaged in the composition of Rokeby, he observed him noting down even the peculiar little wild flowers and herbs that accidentally grew round and on the side of a crag near his intended cave of Guy Denzil; and on his saying that he need not have taken the trouble, since daisies, violets, and primroses, would have suited his purpose as well as the humble plants he was examining, the poet replied, “that in nature herself no two scenes are exactly alike, and that whoever copied truly what was before his eyes, would possess the same variety in his descriptions, and exhibit apparently an imagination as boundless as the range of nature in the scenes he recorded; whereas, whoever trusted to imagination would soon find his own mind circumscribed and contracted to a few favourite images, and the repetition of these would, sooner or later, produce that very monotony and barrenness which had always haunted descriptive poetry in the hands of any but the patient worshippers of truth.”

Diction.

The other department of the poet’s study relates to the use of the medium through which his ideal creations are to be conveyed to others; in other words, diction, or the choice and arrangement of the words most appropriate to convey the precise shade of meaning, and to convey it divested of all those associations of a low or ludicrous character, which usage sometimes connects with words, and assisted by all the charms of musical sound. All men who seek to command the minds of others through speech must by study learn to apprehend the power and perfect force, as affecting thought, imagination, and passion, of every word which his fellowmen have used for ages as the vivid image of some conception of the soul. They must acquire a perception of the value of words, at once exact, delicate, and passionate. This careful and fond study of language, however, is peculiarly requisite to the poet, and has been carried to higher perfection by them than by prose writers; "because, in the composition of poetry, the mind, attempered to delight, feels more sensitively the exquisite form into which the material expression of its conception is wrought." The very shackles imposed by metre and rhyme, though they may occasionally tempt an inferior poet into the use of a word which is not the one most apt to express his conception, unquestionably only operate as a stimulus to the great poet to make himself master of all the resources of words which the language supplies, so as to comply with the necessities of rhyme and musical sound without sacrificing any portion of the substance of his conception. Without this thorough command of the whole armament of language, and the utmost patience and perseverance in its use, we may be assured that no poet has ever succeeded in attaining a general and permanent popularity. Verse cannot leap full armed from the brain of the poet. The steps which lead from the rudeness of the first conception to the elegance of the last, though they cannot be seen, are undoubtedly many. The ideas must be patiently wrought into shape; words weighed and rejected; shades of meaning of the nicest kind discriminated; associations foreseen and guarded against; and an arrangement of words throughout preserved, which, while it differs from that of prose, never allows the inversions which are admitted in poetry to obscure the meaning. The practice of the greatest poets we know to have been in conformity to these rules. We find Virgil dictating a number of verses in the morning, spending the day in revising, correcting, and reducing them, and comparing himself, as Aulus Gellius mentions, to a she-bear licking her misshapen offspring into shape. We see Petrarch returning day after day to his sonnets, to alter some single word, or make some apparently trifling change in the arrangement of a line. The manuscripts of Ariosto, whose style appears the very perfection of ease, and an almost spontaneous emanation, still exist at Ferrara, and show that many of the favourite passages in the Orlando were written eight times over. Scarcely less attention was bestowed upon the stanzas of the Gerusalemme by Tasso. Milton's study of English speech, and mastery of the artifice of language, as well as the critical care with which he built up "the lofty rhyme," are well known:

> "He with difficulty and labour hard
> Moved on; with difficulty and labour he."

The specimens of Pope's *Iliad* given in Johnson's Life, exhibiting the successive changes which the lines underwent before they assumed that compact and harmonious form in which they appeared before the public, must be in the recollection of every reader. And we see from the letters of Lord Byron that the same laborious process of polishing was not disdained even by his impetuous mind. It is indeed scarcely too much to say, that no composition of any length which has obtained a permanent popularity was ever thrown off at a heat; and that the nearer the work approaches to the appearance of spontaneity, the greater has in general been the extent of the labour which has been employed upon it.

Q lities co mon to al good p try.

Such being the qualities and habits of mind that make the poet, it may be asked what are the common qualities to be found in all poetry which has permanently commanded the admiration of mankind. Milton has endeavoured to condense these into a sentence. Poetry, he says, must be "simple, sensuous, passionate."

Poetry must be simple.

By the first quality, simplicity, which applies both to the matter and the language, he seems to indicate the necessity of dealing in poetry with the simple elements of human nature; keeping the broad highways of feeling, avoiding affectation of sentiment, over-refinement, or morbid peculiarity of any kind. "It distinguishes poetry from the arduous processes of science labouring towards an end not yet arrived at, and supposes a smooth and finished road on which the reader is to walk onward easily, with streams murmuring by his side, and trees, and flowers, and human dwellings, to make his journey as delightful as the object of it is desirable, instead of having to toil with the pioneers, and painfully to make the road on which others are to travel."[1] And unquestionably it is the fact, that the works of the greatest poets are the simplest, the most level to ordinary apprehension, the most adapted to ordinary sympathies. Homer, in whose works nature is reflected without change, is understood and relished equally by the youth and the man, by nations the most distant from each other both in space and time. Shakspeare, in like manner, in whose works we can detect no subjective influence produced by his own mind, and who seems to range like the universal sun over the provinces of emotion, enlightening all alike, produces the same deep impression on the learned and the unlearned. Both concur in this, that they do not paint the exceptional, but the customary; not the peculiarities, but the common features of humanity; and that they paint these broadly and simply, instead of endeavouring, by a complex apparatus of singular traits and colours, to display their own artistic skill.

Sensuous.

The second of the qualities enumerated by Milton is, that poetry must be "sensuous;" that is, that it shall have that character of sensible reality which shall prevent its degenerating into mere dreams and abstractions; that it shall be so far connected with the world about us, and with our actual interests and pursuits as not to appear altogether the creature of another sphere, and this both as to the nature of the subject and the definite nature of the imagery employed upon it. The right understanding and application of this rule would have saved the world from many of those hazy poetical abstractions, or attempts to transmute political or metaphysical theories into poetry, with which, in the present age in particular, the public has been inundated. It is the neglect of it which renders the metaphysical poetry of the sixteenth century, with all its grandeur and force of thought, so often unreadable.

Passionate.

The third requisite of poetry is that it be passionate. It is not enough that thought and imagery be sensuous, or objective and definite; the *passio vera* of humanity, as Coleridge remarks, must animate both. It is by our sympathies that poetry lays its strongest hold on us; and it is by the representation of passion that these must be set in motion. Even the lower and more level departments of poetry must be warmed by it; of the epic, and still more the dramatic, it constitutes the mainspring. Didactic and descriptive poetry would become wearisome were they not enlivened by the occasional introduction of scenes awakening the feelings of love or pity. In lyric poetry, the song constantly exhibits its condensed expression; in fact, so powerful is its influence, that genuine passion will often support a poem which has but slender claims to fancy or imagination. The mere literal and truthful exhibition of the greater passions of our nature so stirs within us the sense of the sublime or the terrible, so rouses our curiosity and suspense, that for a time we are willing to dispense with the more ethereal colouring which imagination might impart to them. We say, however, for a time only; for a literal picture of human passions, if prolonged through a whole drama, and unrelieved by imagery or the expression of calmer thought, is felt to be painful and harrowing to the mind. Such is the effect produced by the Newgate Calendar dramas of Lillo, George Barnwell, Arden of Feversham, and the Fatal Curiosity, and by the similar German tragedy of Werner, the Twenty-Ninth of February. So great was the effect produced by the scene in Lillo's play representing the murder of Arden, that the audience, unable to endure the excitement of the representation, rose up with one accord and interrupted it. Appeals to our passions, presented in this bleak and naked reality, have the same painful effect upon the mind which exhibitions of crime and suffering have in real life. To make them produce a pleasing effect in poetry, at least for any length of time, they must be blended with associations of a less vulgar and less agitating kind; and the pain which attends our sympathy must be tempered by the soothing imagery suggested by the imaginative and reflective faculties.

---

[1] Coleridge's *Literary Remains*, vol. ii. p. 10.

Poetry changes with society.

The qualities enumerated by Milton may be considered as fixed and inherent in all good poetry; beyond these it is difficult to point out any which are of permanent and universal necessity. That poetry which seeks to please through our sympathies must shift and vary, both in its themes and in the manner of treating them, with the changes of society, is a truism on which it is needless to enlarge. If the opinions of men change, if their habits and the objects and associations which interest them alter, poetry must adapt itself to this altered state of things. It does so indeed unconsciously; it cannot avoid doing so; for the poet's own nature has partaken of the change.

Effect of increased civilization on poetry.

It is a more important question, whether the progress of society, the advancement in civilization, and the moral habits and intellectual constitution which accompany it, operate favourably or unfavourably on poetry; in other words, is there reason to believe that the imaginative faculty in poets, and the sensibilities of their readers, decline with the progress of refinement in the arts; or that the imagination no longer finds the same materials in actual life on which its plastic power can be excited?

The tendency of most of the late inquiries into the question has been towards the opinion of its unfavourable influence. The faculty of imagination is supposed to decline as knowledge becomes more exact; the turn for analysis, which is the characteristic of advancing civilization, and which shows itself in the philosophical character which language assumes, is maintained to be destructive of that individuality and distinctness which is the life of poetry; substituting general abstractions for particulars, vague phrases instead of images, and personified qualities instead of men. In a half-civilized state of society, too, life is a romance, a tissue of adventures, powerfully exciting the feelings of fear, wonder, and enthusiasm. In more refined periods these sources of excitement cease; and, even where they exist, they are veiled by the caution which the fear of ridicule produces, a restraint which in the ruder periods of society is comparatively unknown. Hence both the imagination of the poet and the sensibilities of the reader of poetry are chilled. "Poetry," says one of the ablest exponents of this unfavourable view of the effects of civilization on the arts, "produces an illusion on the eye of the mind, as a magic lantern produces an illusion on the eye of the body. And as the magic lantern acts best in a dark room, poetry effects its purpose most completely in a dark age. As the light of knowledge breaks in upon its exhibitions—as the outlines of certainty become more and more definite, and the shades of probability more and more distinct—the hues and lineaments of the phantoms which it calls up grow fainter and fainter. We cannot unite the incompatible advantages of reality and deception, the clear discernment of truth and the exquisite enjoyment of fiction."

Yet these observations, though true to some extent, must be received also with some qualification. If language loses something in picturesqueness, it becomes far more pliant, far better adapted to convey the exact idea intended; if phrases which originally conveyed images have by long use ceased to be metaphorical, we see that genius is constantly creating and giving currency to new combinations. Knowledge and learning and mechanical improvements, if they tend to repress enthusiastic feeling, at least supply poetry with a host of illustrations unknown to earlier periods; but, above all, it may be doubted whether the enthusiastic and imaginative faculties within us can ever be materially affected by the changes of society, however their outward manifestations may be repressed. Whilst men feel that they are connected with eternity, mysteriously surrounded by influences which they feel and acknowledge though they cannot account for them; whilst love still holds a place in the heart, and carries the spirit of romance into the barest realities of existence; whilst men have a country to honour and defend; whilst they can still be animated to enthusiastic concert in the cause of humanity; whilst the strange accidents by which even our decorous and conventional course of life is at times broken, still present to them a thousand scenes of joy or calamity; there seems little reason to apprehend that the imaginative faculty can ever be so impaired from want of external nutriment or inward vigour, but that a truly great poet will always find the means of speaking to the hearts and sympathies of men, in different language it may be, but with undiminished power.

Still less reason is there for the apprehension, that the materials for description and illustration which external nature offers to the poet are likely to be in time exhausted, or even materially encroached upon. Certainly the first and the more obvious of its features are caught by the first labourers in the field of poetry, with a truth and liveliness which no subsequent efforts are likely to surpass; and if poetical imitation were, like literal landscape or portrait painting, a mere transcript of the scene before us, there might be reason to think that all the more striking aspects and points of view would, in the course of time, come to be exhausted, and the poet driven either to mere repetition in a feebler form, or to seek for novelty by endeavouring to turn to account the materials which his predecessors had thrown aside as least fit for their purposes. But when it is recollected how infinite are the varieties and combinations of which the objects of moral and material nature are susceptible, how largely, too, a creative and changing power is exercised in poetical imitation; and in how many different lights, independently of this process of imaginative change, the objects around us are placed by natural differences of associations in the person who contemplates them; it may be safely assumed that the materials of poetry are inexhaustible.

That poetry must have existed from the very earliest periods is undoubted. As the expression in language, of that feeling of excitement and elevation produced either by moral or material grandeur or beauty, it had its seat and origin in human nature itself, and in its simplest form must necessarily have existed as soon as man felt the desire of recording his impressions, or communicating them to others. In its first shape it may have been destitute either of rhythm or metre; although so close is the connection between that state of the imagination which gives birth to poetical conceptions, and a tendency to assist the effect of these by certain intonations of the voice approaching to musical sounds, that it is far more probable that even from the first something of measure was imparted to it, probably without effort or consciousness on the part of the reciter. At any rate, the power of measure as an assistant to memory, and as furnishing a species of gratification to the ear, apart from the mere effect of the ideas upon the mind, could not fail to be soon perceived and acted upon. At first, in fact, poetry and music seem to have been constantly associated; for the study of music, as something separate from the accompaniment of words, is one which arises only at a later period; and in all the poetical compositions which have descended to us, the elements of versification, or division of lines into certain measures, are discernible.

Hebrew Poetry.

The poetry of the Hebrews is the oldest in the world. It stands apart from all the rest, in solitary grandeur, like a pillar of fire in the poetical wilderness. The poetry of Greece, for instance, only begins to exist centuries after the noblest efforts of the Hebrew muse had been produced and committed to writing. Even the oldest poetry of the Arabians, whose language is a kindred one to the Hebrew, is of far more recent date than the Jewish Scriptures, in fact not much older than the time of Mahommed. The Hebrew poetry, as it has come down to us, seems limited in its field, though within that field it has attained a mastery never excelled. Almost all its compositions are lyrical, and chiefly in the highest department of the lyric, resembling, though in a less regular and artful form, the ode of the classical poetry. Its characteristics appear to be unequalled majesty of thought and expression, a fervour and flow which, more than in any other poetry in existence, suggest the idea of an inspiration or divine afflatus, dictating, through the poet as a mere organ, the sublimest ideas in words of corresponding weight and grandeur; a profusion of imagery and illustration, which, though it at first appears excessive and overpowering to the critic of modern times, and colder climes, is seen upon further study to be in the closest harmony with the Hebrew character, and that of all the oriental nations, and is remarkable for the absence of any thing farfetched or elaborate; a rapid desultory movement from one train of thought or illustration to another, without formally supplying the links in the chain of association which have led to the new topic,—as if the poet relied upon a corresponding excitement in his readers or hearers to supply that elevation and reach of poetical vision necessary for tracing the chain of ideas from first to last. It is certain, however, that to the Hebrews themselves there was much less of abruptness and want of connection in their lyrics than at first sight appears to us; and that slight hints were sufficient to awaken trains of associations to which, from our altered circumstances and character of mind, we have now no clue; and this observation, in fact, applies equally to the Hebrew and to great part of the classical poetry of Greece and Rome.

ircumtances rom which derived s peculiar haracter.

When we look to the Hebrew character and poetry, and to the local situation and manners of the country, we perceive a combination of circumstances highly favourable to the growth and development of that department of poetry in which alone they can be said to have attained distinguished eminence. All the elements out of which a great national lyric poetry is formed existed amongst the Hebrews, both as regarded the impulses of the mind and the external influences by which they were surrounded and daily acted on. They had been selected as God's peculiar people from among the nations; they held as it were a commission from heaven, giving them authority over the world; they looked upon themselves as the race from which its Saviour was to spring. They had triumphed, by the divine aid, over the kings, and princes, and Pharaohs of the earth; they had the recollection of all their strange wanderings, their miraculous deliverances, their acquisition of the promised land, and their law given amidst audible thunders and visible smoke from Mount Sinai, in the presence of assembled myriads. They had a religion which, excluding the worship of the Deity under visible symbols, only made the image of the Deity more deeply and impressively worshipped within the temple of the heart and the imagination: while the connection of religion with all the affairs of life; the constant rites and ceremonies and festivals of rejoicing or humiliation; the presence of the Deity, kept before their thoughts by the ark, which was supposed to be his peculiar seat, and the sacredness of which had been more than once guarded or avenged by prodigies; prevented that religion from becoming a mere abstraction, and gave to their conceptions of the Deity a warmth and life peculiarly suited to the poetry of devotion, as blending the ideas of the visible and the spiritual, without any admission of those palpable, material, and degrading conceptions which mingle with and deform, to our associations, the mythological or religious poetry of Grecian polytheism. No commercial pursuits tended to excite among the earlier Hebrews the prosaic love of gain. They were shepherds, husbandmen, or warriors, deriving subsistence from the soil, and attached to it by a train of recollections. Frequent public ceremonies, festivals, jubilees, gave occasion for the assemblage of the people in large masses, for a common purpose; the occasion of all others most likely to call forth, by a common sympathy, the enthusiasm which stimulates the imagination into poetical activity. Add to these a climate bright and cheerful, but admitting also of every variation and interchange of serenity or tempest; a country, the external aspect of which presented the strongest contrasts of barrenness and luxuriance; fertile plains, with mountain ranges of the most bleak and desolate grandeur; gardens like those of Damascus, with dreary lakes like the Dead Sea, whose stagnant waters still spoke of the fall of the cities of the plain, or wildernesses haunted by the lion, the rhinoceros, and the serpent; and it would indeed be matter of surprise if the Hebrew sacred poetry were not characterized by a remarkable feeling of national pride, of sublimity, simplicity, and natural pathos in its sentiment, and by a peculiar freshness, truth, and boldness in its pictures of nature, or illustrations derived from external scenery. The parched plains of Judæa, the rocky top of Sinai, the towers of Damascus, and the gardens of Lebanon and Carmel, supply them with figures or allusions which have an unspeakable charm of picturesqueness and beauty. The climate is vividly brought before us in the allusions to the wellsprings that water the desert, and to the shadow of the great rock in a weary land. We see the simple character of their life in their pastoral images, so constantly derived from the tending of flocks and herds; imagery so congenial to their minds, that it is employed by the Author of our faith in some of the most touching passages of the New Testament. Such is the character of those books of the Hebrew Scriptures which are on all hands admitted to be poetical, though we know too little of the laws of Hebrew prosody to be able to say whether they are written in verse, though a species of rhythm, and apparent equality in the divisions of portions of the sentences, appear to indicate that they are. Such are the Book of Psalms; one of which (the ninetieth) is even ascribed to Moses, whilst several others were the production of predecessors or contemporaries of David. It is certain, however, that those ascribed to him are the finest and the most affecting of the whole, though perhaps not the most magnificent in point of stateliness of diction and imagery. "Nor is it in tragic so much as in joyous expression," says Mr Campbell, "that I conceive the power of his genius to consist. Its most inspired aspect appears to present itself when he looks abroad on the universe with the eye of a poet and with the breast of a glad and grateful worshipper. When he looks up to the starry firmament, his soul assimilates to the splendour and serenity which he contemplates. His lofty but bland spirit of devotion peculiarly reigns in the eighth and in the nineteenth psalms. But, above all, it expands itself in the 114th into a minute and richly diversified picture of the creation. Verse after verse in that psalm leads on the mind through the various objects of nature, as through a mighty landscape; and the atmosphere of the scene is coloured, not with a dim or mystic, but with a warm and clear light of religious feeling. He spreads his sympathies over the face of the world, and rejoices in the power and goodness of its protecting Deity. The impressions of that exquisite ode dilate the heart with a pleasure too instinctive and simple to be described."[1] Such also are the Song of Solomon, the Proverbs, Ecclesiastes, the Lamentations, and the Book of Job, with large portions of the prophetic books, and occasional passages even in the narrative books, such as the Song of Moses and Miriam, Jacob's dying prophecies to his sons, the triumphal chant of Deborah, Balak's involuntary blessing on the people whom he came to curse, and, above all, the exquisitely pathetic and beautiful lamentation of David over Saul and Jonathan. Amongst the Hebrew prophets, viewing their writings apart from their divine inspiration, and merely in the light of poetical compositions, the highest rank is universally ascribed to Isaiah; and that on account of the union of excellencies which his sacred poetry exhibits. Deeply pathetic in some portions, as in those where he paints the destruction which is about to fall upon Judah; awfully sublime in others, as where he describes the descent of the Assyrian king into the regions of hell, while all the dead monarchs of the earth rise up to greet him with reproaches; he rises with equal ease to themes of rapturous exultation, or spreads out in minute portraiture all the tranquil and soothing images of a coming millennium. "Joel," says Mr Campbell, "may be deemed to surpass him in continuity, and both Joel and Habakkuk are at moments more sublime. But their compositions are much shorter than his, and give us not the same conception of copious and unwearied inspiration. Isaiah's genius goes farther on an even wing, and burns longer with an unwavering fire. When he has merely to relate, his language has the utmost plainness; and his expositions are remarkably clear, considering the nature of oracular poetry. He unites the same simplicity with his rich and high visionary scenes, which are neither meagre like Jeremiah's, nor ambitiously overwrought and complex like Ezekiel's. A deliberate air, a divine self-possession, turns the very scorn and wrath of his spirit into movements of grace and beauty."

Jeremiah and Ezekiel belong to the declining period of Hebrew literature. They had fallen upon the evil days of their country, and the influence which its misfortunes and degradation produced on the mind, is peculiarly visible in the melancholy strains of Jeremiah. "His genius seems to bend, his voice to falter, under the burden of prophecy; and though sometimes pleasingly affecting, he generally prolongs the accents of grief to monotony, and seldom avoids tautology except where he abridges the works of other prophets." Ezekiel is the last great prophetic poet of the Hebrew line; and opinions have been divided as to the poetical rank to which he is entitled. Dr Lowth thinks that he is not excelled in sublimity even by Isaiah himself; Michaelis, on the contrary, that he displays more luxuriance in amplifying and decorating his subject than is consistent with true poetical fervour. Mr Campbell adopts the view of Michaelis, but adds, that the fancy of Ezekiel is daring and ingenious. Ingenious hardly appears to be the term applicable to the imagination of Ezekiel, which revels with peculiar pleasure in visions of a mystical, and, it must be admitted, somewhat confused sublimity. Some passages, however, are most powerfully impressive, such as the vision of the four cherubims in the first chapter, and the resurrection of the dry bones in the thirty-seventh, when there was "a noise and a shaking, and the bones came together, bone unto his bone;" and the prophet calls unto the wind, "Come from the four winds, O breath, and breathe upon these slain, that they may live; and they stood up on their feet, an exceeding great army."

But whilst the Hebrew poetry equals, and indeed far excels, that of any other nation in the sacred lyric, it is singularly defective in the other departments. The Song of Solomon, laying aside its spiritual meaning, may be admitted to be a fine specimen of the pastoral: but of dramatic and narrative poetry the Hebrews have left no specimens; for, though the book of Job has to a certain extent a dramatic form, it has clearly nothing of the essential qualities of the drama. This has been ascribed mainly to the theocratic nature of the Jewish constitution, in which the Levites or priesthood formed the sole and literary aristocracy; thus devoting poetry exclusively to religious themes. But, considering the ample field which the Jewish national religious history afforded, it is not easy to see why, if the genius of the people had inclined toward narrative or dramatic poetry, the Exodus, the wanderings in the desert, the wars carried on under the judges, and the many other striking events which gave interest to their annals, should not have been embodied in verse, as they were in prose, in the narrative books of the Old Testament.

But, though the poetry of the Hebrews is the first in the order of time, it cannot properly be regarded as the fountain-head of that literature, the course and connection of which we trace in an unbroken series of great works down to the present time.

The sacred poetry of the Hebrews, no doubt, impressed upon the literature of Christianity some strong and remarkable features; but it was from the fountain of classical literature that the genius of modern Europe first drew its inspiration. It is therefore to Greece that we must turn, as the head of that great family of literature with which we feel ourselves connected by relationship of thought and association.

Greek Poetry

On turning from the poetry of the Hebrews to that of Greece, we are immediately struck with one distinctive feature, which, as applicable to the whole of its poetry, we may notice before adverting to the different departments into which it is subdivided, viz. the more palpable, material, and distinct character of all its conceptions and imagery. This immaterial, vague, and spiritual character of the Hebrew poetry, dwelling more on emotions of the mind than on actions, and on the invisible rather than the outward and visible, is unquestionably to be ascribed in a great measure to the predominance, in the national mind, of a pure and elevating religious creed. On the other hand, the Grecian mind, formed under the influence of a mythology which was in fact a mere deification of the material world, and which certainly exercised no strong influence save on the fancy, banished those themes and trains of thought which led beyond the visible diurnal sphere, and, concentrating its attention upon the present, gave to all its imagery a distinctness of outline, a simplicity and pellucid clearness in the thought, which, if less suited than the Hebrew to the excitement of the evidences of the sublime, was certainly in a corresponding degree favourable to the creation of beauty. The Hebrew poetry, therefore, is contemplative and subjective; the Grecian plastic and objective.

In an outline like the present, of the progress of poetry, it is needless to dwell upon the subject of the antè-homeric poets of Greece. That there were poets before Homer, we know; and this is really the extent of what is known on the subject. That the *art* of poetry had been cultivated to a considerable extent, that its principles had been subjected to reflection and experiment, when Homer lived, is as clear as internal evidence in any case can make it.

---

[1] Campbell's Lectures on Poetry, i.

Poetry improves only as painting and sculpture rise to perfection. "In sculpture," says Herder, "what a track must it have travelled over in passing from the figures on the chest of Cypselus to the decorations of the Propyleia and the Minerva of Phidias, or from the sculptures of Dædalus to the Olympic Jupiter. A like track was travelled by poetry in advancing from the rude lays in honour of gods and chiefs to the Homeric Epos." We know, indeed, that many of the minstrels before Homer had sung theogonies and cosmogonies, the adventures of Titans and heroes, of Hercules, Theseus, and the Argonauts; and in all probability the legends of the siege of Troy, and the return of the chiefs engaged in that enterprise, had formed the subject of many a ballad or rhapsody, ere a Homer arose to give them unity, proportion, and poetic life. All these have faded and been forgotten, for the tablet of human memory is narrow, and, to give room for the last and best, the older and ruder inscriptions must be erazed. Not one of these, accordingly, has descended to us in any authentic form; whilst the spuriousness of most of the Orphic poetry is unquestionable. Whether even an Orpheus ever existed, was doubted by Aristotle; and Herodotus distinctly states his belief, that the poets given out as older than Homer were in fact of more recent date.

We do not enter into the details of the question whether the works which bear the name of Homer were the productions of one man, and written in their present form at the period commonly ascribed to them, namely, nine hundred years before Christ, or whether they were originally the work of many rhapsodists, in portions separate and distinct, and afterwards woven together in a collected form about the time of Solon and Pisistratus. The question is, in fact, of less importance in reference to the history of poetry than might at first sight appear. For whatever view may be adopted, it is clear that the spirit, the tone, and the manners which are described in the separate lays, supposed to have been ultimately incorporated in one, are those of the earlier and not of the later period, and that the Iliad paints the Grecian mind and character as it appeared three or four hundred years before the time of Solon, and that from draughts made at the time. If so, the only way in which the adoption of the modern theory of Wolff affects the question is, that it deprives Homer of the merit of one grand general design, consistently followed out. It is certain, however, that whatever difficulties may attend the supposition of the Iliad and Odyssey being written by one man, in their present form, and at the early date ascribed to them, and preserved in the absence of writing by mere oral tradition, the difficulties on the other side are infinitely greater. To suppose that a set of scattered lays, composed by a number of unconnected minstrels, should ever have been made to cohere so smoothly and compactly, evincing such perfect unity of plot and purpose; that they should have been confined to so small a portion of the Trojan legendary history, and have given such prominence to a single Thessalian hero; seems a supposition far more startling than any that attends the belief that the Iliad is the work of a single author. "For inspiration is a solitary creative spirit; and it is not to knots and groups, or accidental fabricators, that she has ever intrusted those great conceptions in poetry or painting, or the fine arts, that have commanded the permanent homage of mankind." Many smaller additions, by other hands, in the same spirit and style, may have been afterwards superinduced upon the original work of Homer. (See the article HOMER.)

Epic poetry.

The two great poems of Homer are the first specimens of *The Epic*, or narrative poem. It is, in fact, from the Iliad in particular that our conceptions of an epic poem have been derived, and its canons deduced. What Homer has done has been consecrated as establishing inviolable rules to be observed by his successors. The epic is, upon the whole, the noblest form of poetry; that which demands the highest and most sustained power of imagination, combined with the simplest and purest taste. The power of tragedy is greater for the moment; for its presentations, assisted by action and visible form, are more vivid; but the epic, possessing a wider compass, and painting only by words to the eye of the mind, has a more diversified, enduring, and tranquil operation. Rapidity, strength of passion, vehement and animated dialogue, are the essential requisites of tragedy; a calm, sustained, progressive, and sober majesty the characteristic of the epic. "Of dramatic pieces," says Herder, "we remember sentences; the characters move before our eyes, we feel their emotions with them. But this emotion being stronger, is also briefer; it passes away. The epopee, with its more quiet working, with its proportions too vast for any stage to compass, fills the soul, and there abides." The other points noticed by Aristotle, "revolutions of fortune, recognitions, characters, passions," are common to both, as well as to fictitious composition in prose. Every romance written on any high principle is, in fact, a prose epic; the epopee in verse merely adds to the other sources of interest the charm of poetical diction, and of those elaborate ornaments of figures and similes, which, though stately and appropriate in verse, only produce a bombastic and ridiculous effect in the prose of Fenelon, or still more in that of Macpherson.

Essentials of the epic.

An epic, then, is the poetical development, in narrative, of some great and interesting event, or series of events, sufficiently separate from what goes before or follows, to possess the character of a whole; having, therefore, a clear and distinct beginning, middle, and end; an action simple at first, leading into a complication of plot, and terminating in a natural and soothing solution. These are its essentials; amongst its accidental features are the employment of supernatural agency as a medium either of heightening emotion or of conducting the plot; the introduction of episodes, of formal addresses, invocations, and similes; matters which have no essential connection with epic poetry, and the propriety of the introduction of which varies with the theme, the age, and the national associations of the poet.

How far suited to modern times.

To the confusion of these accidental qualities, many of which are certainly quite unsuited to the taste of modern times, with those essential features which must have an equal interest for all time, must be ascribed the numerous failures which in modern times have thrown a certain discredit and air of ridicule upon the epic poem; as well as the belief that appears to prevail, that the time for epic poetry is past. Unquestionably any epic now written which deals with fabulous mythologies or exploded superstitions, and employs in the nineteenth century the long elaborate speeches, the minutely touched similes, the formal enumeration of ships, and muster-rolls of regiments, which suited the primitive times of Homer, when description was new, will probably share the fate of the Leonidas of Glover, or the Epigoniad of Wilkie. But in the hands of a poet selecting a theme of sufficient natural and human interest, remote enough to allow play for the imagination, yet near enough to make us understand and sympathize with his actors, and treating it, not in a slavish spirit of imagination, but with the vigour and independence of original thought, we are persuaded that the epic would be found to have lost none of its power. It seems to be an entirely mistaken opinion, that the epic is only the production of an early and comparatively simple state of society, and therefore unlikely to harmonize with the more complex nature and critical taste of more advanced civilization. On the contrary, the Jerusalem of Tasso, the Paradise Lost of

Milton, and the Lusiad of Camoens, the only three modern epics which deserve the name, are the productions of what may be termed the golden age in point of taste in each country, and of individuals uniting to poetical inspiration all the stores which the widest reading and most sedulous cultivation of learning could supply.

The Homeric epics, and their characteristics.

The great poems of Homer are distinguished from all modern epics, by their wonderful air of truth, their broad clear portraiture of character, infinitely varied, and yet not antithetically contrasted; their perfect absence of all affectation, false sentiment, or exaggeration, either in character or sentiment; their calm and impartial spirit; their serenity, cheerfulness, and good sense. Such a union is indeed not to be expected in a modern state of society; after poetical description has already traced all the leading outlines both of moral and material nature, and when men, insensibly and unavoidably subjecting the influences from things without to a process of intellectual chemistry from within, and thus, connecting them with peculiar associations, cease to have either the power or the inclination of simply reflecting back on their verses, as in a mirror, the impressions of nature as they fall upon the mind. Neither, although the power of delineation existed, can it ever be expected that such materials for broad, simple, and effective painting can be found in modern times, when differences of character are veiled, if not in a great measure obliterated, by community of education and habits, or are converted into mere humours or peculiarities, to which the shades of distinction are too minute for any grand poetical effect.

Even the greatest of our modern epic poets, in painting the manners and the moral habitudes to which chivalry gave birth, laboured under the disadvantages of pourtraying feelings which, springing, as they had done, out of a visionary and unreal, because exaggerated sentiment, had a tendency to run into caricature, and to give a monotonous and hyperbolical cast to their delineations of human character. The beings painted by Homer, who himself lived upon the outskirts of the heroic times of Greece, were in their features the men whom he saw around him; beings natural, open, and unsophisticated, both in their good and bad qualities: the manners simple, primitive, and homely, yet not without a touch of grave courtesy and refinement; the scenery which forms the foreground or background of his human groups as yet undepicted, the incidents through which they pass unhackneyed; all nature was before him where to choose: while the language which was to be employed as the medium of his art, neither debased by vulgar associations, nor diluted from its original freshness and strength by metaphysical refinements, which diminish its picturesqueness in proportion as they render it more complex and philosophical, affected the mind with all the distinctness of sounds and colours, and stamped upon it an impression fresh and immediate, as from the signet of nature.

The power of invention displayed by Homer in his two great poems in the conception of character, can only be fully appreciated when we recollect, that the germ or outline of almost every character which has since figured in epic poetry is to be found in the Iliad. Now, though the wonderful variety of his incidents, his battles, sieges, and storms, his nocturnal adventures, his combats of gods and men, and his scenes of enchantment, may have been in a considerable degree derived from his predecessors, and, in fact, the hereditary and traditional *properties* of the ballad minstrels of Greece, it is impossible to conceive that he could have derived much aid from this source in giving individuality and life to character. And yet, with the exception of characters under the influence of the passion of love, such as Dido, Armida, and Erminia, scarcely any substantial addition has been made to the picture gallery of Homer by later epic poets. His characters, in fact, have been like stereotypes, from which new impressions are constantly reproduced. Achilles, with his union of ferocity and gentleness, generosity and vindictive feeling, has been the model of all our mixed characters of passion since, and reappears in Turnus and Rinaldo; just as the kingly Agamemnon, with his grave dignity, has formed the archetype of those which represent the ascendency of reflection, and the moral power of sustained and tranquil grandeur, as in the Godfrey of Tasso's poem.

The Iliad.

The characters of the Iliad are naturally the more varied, because its subject was a great public event, and the actors were the congregated princes and heroes of Greece and Asia; the Odyssey is the poem of domestic life, the tale of the fortunes of a single hero, to whom all the other personages are purposely placed in subordination, but whose character, by this isolation, gains a degree of distinctness and natural truth absolutely unequalled in fiction, save in some of the creations of Shakspeare. The remarks of Mr Campbell on the characters of the Iliad are so just and beautiful, that we cannot deny ourselves the pleasure of quoting them.

"Achilles, in the centre, is of the order of spirits that electrify and command mankind. His alarming and sensitive being is the soul of the Iliad, and his very absence and repose are the causes of its disastrous action. He is unquestionably ferocious, but his quarrel is just; he is wronged, high minded, hating falsehood like the gates of hell, young, beautiful, and predestined to fall. Casual glimpses of his manners are also given, that interestingly soften our conception of him. He is the only hero of the Iliad who amuses himself with music and poetry. The deputies of the army find him in his tent playing on his lyre, and chanting heroic songs; and, though he knows their hateful errand, he receives them with a calm and manly benignity. Horace does him injustice when he calls him a disclaimer of laws, and inexorable; for he melts into tears at the prostrate gray hairs of Priam, the father of the slayer of his friend, though he had lately withstood all the eloquence of Nestor.

"It shows the security of Homer in his inspiration to have introduced such an opponent to Achilles as Hector. But when he leads us to Troy, he makes us Trojans in our affections, and almost seems to become so himself. Prodigal in sympathy with the events and agents which he conjures up, his imagination as tenderly conceives the lamentations of Hecuba, and the heart-sick swoon of Andromache, as it makes itself impetuously congenial with the vengeance of Achilles. Like nature, he is fruitful in creating characters, and, like her, impartial in distributing and intrusting virtues to contending parties. Conscious that Achilles could shine by his own light, he fears not to show us his image through tears for the fate of Hector. In delineating Hector by the eulogies of his weeping country and friends, the climax is exquisitely perfected by Helen. All others who had bewailed him, she says, were bound to him by reciprocal ties; but hers was the grief of gratitude for the undeserved and gratuitous kindness of his mighty heart. He had interposed when others had reproached her; he had soothed her when her tears flowed at their reproaches.

"Æneas creates a less ardent, though still respectable interest; and it is increased by a hint, which is thrown out with an air of minute historical probability, that Priam was jealous of his greatness, and that his virtues had been partially thrown into the shade. What expression in every figure of this mighty tablet! What diversity even between men incompetent to great actions; as between the abject coward and vulgar braggart Thersites, and the gay good-natured Paris, whose spirit, though sunk in luxury, still shows some traces of his noble breed! The stout heart and arm of Ajax stand him in lieu of all piety, craft, or sensibility; whilst Sarpedon, bleeding in warfare not his own, spends his last generous breath in exhorting the brave to rally the battle. Homer is above all artificial antithesis in the painting of character; but in describing natures remotely different, he could not avoid exhibiting contrasts; and that which is visible between Achilles and Ulysses is as perfect as heroic nature can afford.

"The youthful Diomed is, among the Greeks, next to Achilles, the apparent favourite of the poet: all spirit and lustre, his valour burns like 'the unwearied fire that plays on his shield and crest.' Like Achilles, he is insulted by Agamemnon, who charges him with cowardice on the eve of battle; but he is wise as well as warlike, and it is not till his actions have belied the imputation, that he retaliates upon his commander. When the Greeks have been worsted, and when Agamemnon proposes abandoning the siege, Diomed, the youngest of all the chiefs, rises in the council, and gives him a dignified rebuke. Agamemnon himself is not without the virtues of fraternal affection, and willingness to listen to able counsellors. He has also his day of distinction in the field. But his importance altogether is more royal than personal, and his faults are made conspicuous by his supremacy. Alternately presumptuous and despondent, he is the readiest to tax others with deficient courage, and the first himself to despair under public reverses. He is also unmerciful in victory. The cry for quarter is addressed to him in vain, and he makes two of the most atrocious refusals to spare that occur in the Iliad. It has been remarked, that Homer speaks as a friend to royal government; but still he describes it as too limited, or rather as too undefined, to be despotic; and the chiefs in the councils of the Iliad present us with a sort of Greek picture of Gothic feudalism. And if he shows respect for monarchy, he makes his kings no monopolists of virtue. In poetical justice, he seems to have thought it sufficient to give Agamemnon the diadem, and a few good qualities, as his share of importance in the poem, leaving brighter heroic endowments to chiefs subordinate in political power.

"Amidst these forms which the Iliad exhibits in the bloom or strength of heroism, the aged characters are no less happily distinguished. Nestor looks back on a life of greatness and wisdom:—he has no rival in venerable years; his powers have reached the last ripeness of experience, but they have also something of the mellow tint that precedes decay. He dwells on his own exploits with an egotism and fulness that could only be endured in the most ancient of men. Phœnix, the friend of Achilles, on the other hand, is also old, but his youth had been embittered by misery and vindictive passions; and when he comes to exhort the hero against excessive resentment, he confesses his early errors in a tone very different from the self-complacency of Nestor.

"Priam is neither very wise nor energetic; but his heart is warm with natural affections, and his woes and years sustain our reverence and solicitude. When the wail of the Trojans bursts from their walls, at the sight of Hector dragged in triumph by his conqueror, when the frantic father implores his friends to let him go forth and implore the pity of the destroyer, the struggle of his people to detain him, and the voice of his instinctive agony, surpass almost everything in the pathos of poetry, and affect us more like an event passing before our eyes, than a scene of fictitious calamity. Never was the contrast of weakness and strength more fearful, than when he throws himself at the feet of Achilles, whilst his feeble perspicacity makes us tremble at every moment, lest he should light up the inflammable temper of Achilles, fluctuating between wrath and compassion. Yet, hallowed by paternal sorrow, age and weakness prevail. The old man accomplishes his point, and the terrific victor condescends to the delicacy of even veiling Hector's corpse from his view."

The Odyssey.

The Odyssey, with certain common resemblances to the Iliad, is marked also by striking differences; so great, indeed, as to afford room for believing, not that it was the work of several hands, but that it may be the work of a different poet from the author of the Iliad. None of the gods and goddesses who play a part both in the Iliad and Odyssey appear the same in the latter poem as in the former. Jupiter, the representative of force or power, and the arbiter of all things in the Iliad, resigns the conduct of the hero to Minerva, the personification of wisdom. Menelaus, Helen, and Ulysses himself, leave a different impression on the mind. Manners and morals have changed. There is a perceptible advance in knowledge and the mechanical arts. There seems a decline in physical strength. The chivalrous spirit of the Iliad is exchanged for a more prudential and calculating one. Voyaging and wandering come in place of warfare. The qualities most valued are no longer the wild strength and energy of Achilles, but the self-possession, energy, forecast, invention, and eloquence of Ulysses. The agency of Magic, in room of a purely divine agency, a power of which we have no hint in the Iliad, finds a place. Wonders and prodigies are scattered with a profusion unknown to the Iliad. Many portions of the Odyssey have an air of resemblance to the Arabian Nights; and Sinbad would seem to have borrowed more than one of his adventures from Ulysses. It is not even difficult to perceive that the vocabulary and syntax of the language have in some measure altered. Each poem seems, as Herder remarks, to have its peculiar atmosphere, its sky, its panorama of objects in the upper, the middle, and the nether world.

Ulysses, the hero of the latter poem, is a conception more in harmony with ancient than modern views of heroism. Our ideas on the subject have been so strongly influenced by those notions of the point of honour introduced by chivalry, that we do not easily sympathize with a hero who, though not deficient in bravery, is always more ready to employ craft than courage, and only appeals to arms when artifice is found to be ineffectual. The character embodies, as Mr Coleridge observes, the idea of an accomplished man of the world, after the manner of ancient paganism; and it is therefore with some effort that we, whose ideal of such a personage is so different, interest ourselves in his fate. Yet he does make his way at last into our affections. His character grows upon us like the gradual influence of good sense. Human traits peep forth under the guise of impassive constancy and caution. His home-sick longings for Ithaca, his abandonment to the power of love under the influence of Circe, remind us of our common humanity. He bears his trials so firmly, he steers through difficulties with such tact and skill, and meets danger, when it must be met, with such self-reliance and courage, that he gradually acquires our admiration; and when we become more familiar with the kindly and warm affections which, after all, burn on in his breast beneath the crust of stoicism, he at last engages our sympathy and our love.

Hesiod.

The poems of Homer are at once the first and the last great specimens of heroic song in Grecian poetry; for it were out of place, in an outline like this, to allude to the middle school of the epic, while even the attempt to revive heroic poetry in the Alexandrian period only proved that its life and soul was extinct. Even in the Odyssey, as already mentioned, we perceive a decline of the enthusiastic and chivalrous spirit, a tendency towards the commercial and the peaceful. Imagination is gradually "fading into the light of common day." This tendency appears, however, far more remarkable in the works of Homer's immediate successor, Hesiod. We say successor, because, although some authorities represent him as older than Homer, and Herodotus speaks of him as Homer's contemporary, the balance of evidence is clearly in favour of the superior antiquity of Homer. The precise date of his appearance,

Adv. Bib.

however, cannot be fixed with more precision than as having been between eight and nine hundred years before Christ. The works which bear his name consist of the Weeks and Days, the Theogony, and the Shield of Hercules, of which the latter is generally regarded as spurious. Looking to the subjects and character of his poems, which are of a domestic and peaceful character; to his style, which, though highly natural and simple, is, in the main, flat, level, and uninspired by high imagination; we should almost imagine that a full century must have elapsed between the Odyssey and the Weeks and Days. The time, adventures, battles, moving accidents by flood and field, and expeditions undertaken to recover some fair runaway "that enchants the world," seem to be for ever gone. In their stead we have an account how labour fell to the lot of man, the story of Pandora, our gradual degeneracy from the gold to the iron age, precepts of agriculture and commerce, moral and religious admonitions, which have much the air of trite proverbs and commonplaces of what deserves no better name than cunning and worldly wisdom; every thing, in short, indicates the triumph of the spirit of peace over that of war. The Theogony is in a somewhat more ambitious style; and, as a catalogue or muster-roll of the Grecian divinities, with a regular deduction of their genealogies, is curious. Unfortunately, however, its finest passage, the battle of the gods and Titans, a piece of genuine vigour and sublimity, appears so different from the style of Hesiod, that it would rather seem interpolated at a later time by some scholar, whose work has in this case very far surpassed his master's. On the whole, Quinctilian has criticised Hesiod with judgment and fairness. "Raro assurgit Hesiodus, magnaque pars ejus in nominibus est occupata; tamen utiles circa præcepta sententiæ lenitasque verborum et compositionis probabilis, daturque ei palma in illo medio genere dicendi."

The Homeric hymns.

The Homeric hymns, a series of compositions in praise of the gods, and probably of a date a little later than the age of Hesiod, seem to bridge over the passage from the epic and heroic poetry to the lyrical. The steps of the transition may even be in some measure traced, in the gradual ascendency acquired by the musical accompaniment which had from the first been employed in the recitation of the epic, but to which a greater prominence was given in the hymns, thus leading on to the decided influence of the lyre and pipe, and consequent accommodation both of the form and character of the poetry to that lyric mould in which it was thenceforward to be cast. Terpander himself composed the music for these Homeric rhapsodies; and Hesiod is said to have been denied admittance to the Pythian games because he could not accompany his verses on the harp. These hymns, strange, quaint, some almost comic; others, like that to Hermes (the finest of all), full of a wild and dancing gaiety; almost all treating the inhabitants of Olympus with a free and easy familiarity; abounding in rapid transitions, invocations, and reflections or sentiments of the writer; prepared the way for the more regular lyric, as it appeared in the strains of Archilochus (about 700 B.C.), to whom is assigned the distinction of being the father of the Grecian lyric.

The lyric poetry of Greece.

The perfection of the Greek lyric had grown out of the intimate connection of poetry with music, fusing the finest results of both into a whole, which, charming the senses and the soul at once, hurried away the listener with an irresistible sweep of enthusiasm. Every thing in the circumstances of Greece contributed to its rapid development and unfailing effect. A spirit of gaiety and social enjoyment was the national characteristic, heightened by the influence of a delightful climate, and by a religion whose airy and fantastic character interposed no gloomy reflection to check the enjoyment of the present. The public and family festivals, sacrifices, games, and poetical contests, assembling multitudes together, exciting the spirit of rivalry, and gratifying the poet as it were with a foretaste of his poetical immortality, the high honours and distinctions everywhere paid to song, rapidly advanced the art to perfection. It is probable, that if the whole mass of the Greek lyric poetry could now be recovered, not only would Horace, Catullus, and the Latin lyric writers, be unquestionably shorn of many of their finest passages, but, in all probability, we should be presented with the noblest and most varied collection that the world has ever produced. For if the light luxurious Bacchanalian spirit of the time be imaged in the graceful trifling of Anacreon's festive songs, we know how the deeper and more gloomy sentiments of a genuine passion were embodied in the burning lines of Sappho; the ardour of military enthusiasm in him who sang his verses to the Spartan fife, Tyrtæus; the inspiring themes of patriotism in "Alcæus, fancy drest, singing the sword in myrtles dressed;" the touching tenderness of maternal affection in the Danae of Simonides, weeping over her child in her frail and sea-beaten prison; and, above all, the loftiest strains of religious fervour, the praises of demigods and heroes, all the pride, pomp, and circumstance of human existence, in the odes of the greatest master of the Grecian lyre, Pindar. But, unfortunately, of the works of the nine who are enumerated by the ancients as forming the constellation of the lyric writers, and embracing the period from the death of Hesiod down to the great era of the Persian war, viz. Pindar, Bacchylides, Sappho, Anacreon, Stesichorus, Simonides, Ibycus, Alcæus, and Alcman, some have completely perished, and of others only the most trifling fragments remain. Anacreon and Pindar are the only two of which we possess any considerable specimens.

Sappho.

Judging from the few fragments we possess of Sappho, the loss of her works is particularly to be deplored; for she appears to have possessed not merely that wild fire and hurry of passion which predominate in her celebrated ode (with which every one is familiar in the version of Phillips), but a tenderness of heart, a power of presenting imagery in a line or a word, not surpassed by any of the ancient writers, and justly entitling her to the lofty title of the Tenth Muse, bestowed upon her by antiquity. How exquisite, for instance, is the fragment preserved by Demetrius Phalereus,

’Εσπερε παντα φερεις
φερεις οἰνον, φερεις αἰγα
φερεις ματερι παιδα.

Thus expanded, yet scarcely improved, by Lord Byron:—

O Hesperus, thou bringest all good things
Home to the weary, to the hungry cheer,
To the young bird the parent's brooding wings,
The welcome stall to the o'erlaboured steer;
Whate'er of peace about our hearthstone clings,
Whate'er our household gods protect of dear,
Are gathered round us by thy look of rest;
Thou bringst the child too to the mother's breast.

Pindar.

Pindar unquestionably occupied the highest place among the Greek lyrists; and though it is certain that we are in possession of only a small part of his works, for he appears to have written on every variety of theme, enough remains to satisfy us that the judgment of antiquity, which raised him to the lyric throne, was well founded. Forty-five triumphal lays, in honour of the victors in the public games, have descended to us, and the character and peculiar merits of these have been described with such eloquence, and at the same time critical justice, by Sir Daniel Sandford, in his able sketch of the rise and progress of literature, that we quote the passage in preference to any remarks of our own.

"The most careless reader of these odes must be struck by the excessive admiration of wealth, magnificence, and every species of greatness, to which we have alluded as a characteristic of Pindar's mind. Splendour was the passion of his soul; splendour of achievement, splendour of renown, splendour of station and outward circumstances. His very pride seems to have suggested to him that nothing but splendour was worthy of his muse. His genius, to use a figure of his own, was the eagle of Jove, that would not be severed from the sceptre and the god. These aristocratic predilections, this enthusiastic attachment to munificent monarchs and chiefs of ancient fame, were in perfect unison with the whole tenor of his destiny; born as he was in the midst of the Pythian festival, living surrounded by shows of solemn pomp, and dying, as he had lived, in the full blaze of public ceremony, in the centre of a theatre, and while rapt in those emotions of rejoicing sympathy which such scenes were sure to awaken in his bosom. To those, however, who may deem apology requisite for the indulgence of so stately a temper, it may be urged in behalf of Pindar, that, as in the case of many remarkable poets, the abstract feeling of veneration was predominant in his mental constitution, and that it was called forth not merely by rank and opulence among mankind, but even more powerfully by the contemplation of the divine attributes. Hence that glow of piety which shines so brightly in his odes, sometimes breaking out in expressions of the deepest awe, or in sublime pictures of deity, and sometimes assuming an aspect of moral beauty, adding force and lustre to the lessons of wisdom. The latter modification of religious feeling has given birth to some of the noblest passages in the poetry of Pindar. He was well aware that emotion does not exclude sentiment; that the ethics of the heart are not less sound than those of the brain; and that nature is often hurried, in moments of excitement, into the innermost shrines of truth. But he knew likewise, that the philosophy of such moments is prompt and peremptory; oracular, not syllogistic; and this knowledge has secured him from frequently offending against the genuine character of lyric song by lengthened trains of moral reflection."

When the lyric poetry of Greece had reached its perfection in Pindar, its drama rose into shape and grandeur in the tragedies of Æschylus. But for the history of the progress and decline of the Greek drama, tragic and comic, the reader is referred to the article DRAMA in this work.

Little remains to be said of the declining portion of Greek poetry. General corruption, introduced by luxury, and the evil principles of the sophists; loss of liberty, when all the powers of Greece had yielded to the sway of Alexander; the introduction of a tumid oriental taste into eloquence and composition in general; such are the features which mark the period from the rise of Alexander the Great to the extinction of the poetical literature of Greece. After the death of Alexander, indeed, a strong effort was made by the Ptolemies to render Alexandria the rival of Athens, and to assemble about their court poets, orators, and men of science. In the latter point only their efforts were successful. Science continued to flourish, and long after Greece had ceased to produce any great works in the fine arts, we find geometrical invention carried to a height by Euclid, whilst the wonder-working science of Archimedes struck the Romans at the siege of Syracuse with terror and astonishment. But eloquence remained, as before, hollow and pompous, whilst poetry was in a great measure wasted in the vain attempt to give life and interest to the abstractions of science. This was the period of the learned or didactic poetry. Mythology, astronomy, botany, were the favourite subjects to which the art of the poet was devoted. One attempt, however, to revive the epic taste is visible in the elegant Argonautics of Apollonius Rhodius. He cannot indeed be regarded as an epic poet, for he wants fire and originality; but he is a graceful compiler of traditions, the effect of which he heightens by occasional touches of tenderness.

heocri-
s.

The most interesting, however, and by far the most original, of the works of the decline of Greek poetry, are the Idylls of Theocritus (270 B. C.). One is at first surprised to find the appearance of the bucolic or pastoral poetry, so late in comparison with the heroic, the lyrical, and the dramatic. As it seems to paint a primitive period of human nature, we are led to think that it would be one of the first forms in which poetry would appear. The truth is, however, that it has generally made its appearance, and has always been most popular, in ages of great social refinement, when excess of luxury in the life of cities drives the mind back upon the supposed simplicity of rural life and its occupations. Such was the case with the Greek Idylls of Theocritus, with the Bucolics of Virgil; with the pastoral dramas of Tasso, Guarini, and Bonarelli; and with the pastorals of Pope and Phillips. They are all the growth of a period of great literary refinement. Frederick Schlegel observes justly, however, that there is an essential error in isolating pastoral poetry, as is generally done, and viewing the country life abstracted from its due situation in that picture of the world and of human life which it is the province of poetry to unfold. "Let us reflect for a moment on those passages in the heroic poems of antiquity, or in the chivalric romances of the moderns, which afford us glimpses of the simplicity and repose of rural manners. Their simplicity appears still more innocent, and their repose still more peaceful, from the situation in which they are placed in the midst of the guilty tumult of wars, and the fierce passions of heroes. Here everything appears in its true and natural connexion, and the poetry is as varied as the world and the men which it professes to represent." It is certain that this treatment of the rural life as a department of life, by narrowing within the most confined limits the materials of the poet, is the cause of that monotony which is generally found to pervade pastoral poetry. Nothing, in fact, becomes more wearisome than the repetition of Arcadian descriptions of the golden age,

Lactis uberes
Cantare rivos atque truncis
Lapsa cavis iterare mella.

But this fault is more prominent amongst the modern, particularly the Italian pastoral writings, than in Theocritus, who has in general painted his shepherds and peasants with a natural and manly simplicity, approaching even, as it seems to modern ideas, to coarseness. His Idylls, as indeed the name implies, are little poetical pictures or representations in miniature, sometimes of mythological subjects, at other times of matters of common life, but almost always amatory in their purpose and termination. With Theocritus may be classed, though far inferior to him in vigour, the "showy Bion and the delicate Moschus," the last names of any note which precede that period of exhaustion, when, the days of high imagination and great works being over, those of mere cleverness and neatness of execution, of slender trifles, epigrams, and anthologies, commenced.

LATIN POETRY.
Its rise.

But as the genius of one nation, yielding to the force of circumstances, declines, nature seems to provide a principle of compensation in the development of that of another. The course of literature and poetry appears to resemble an arctic summer, in which the sun scarcely dips in one quarter of the horizon before he re-appears in another. While the creative energies of Greece either sink into barrenness or expand into a rank and unwholesome luxuriance, as her morals are corrupted, and her liberties impaired and at last extinguished, we perceive in the Italian peninsula the rise of a national character and a literature, destined, alike in arts and arms, in polity or in literature, to give laws to the world.

This not till centuries after the existence of Rome.

Yet Italy, free and independent as she was, and animated by a consciousness of national pride and growing power, exhibits during the first five centuries of her history (735 B. C. to 253 B. C.) a mere blank, so far as poetry is concerned. That she *may* have possessed legendary ballads founded on those various mythic or semi-historical traditions which were afterwards interwoven by Livy into his history of Rome, is not improbable; but of the nature of these we know nothing, of their existence at all we have no certain traces; and nothing can be more fanciful than the extent to which Niebuhr, Schlegel, and other German writers have carried their conjectures on this subject.

Livius Andronicus.

In fact, we know nothing of Roman poetry prior to the introduction of the Greek language and literature, through the conquest of Tarentum (272 B. C.) and Magna Græcia; soon after which the rude attempts of a Greek slave, Livius Andronicus, to translate the Odyssey of Homer into Latin (240 B. C.), first gave the victors some idea of the poetical treasures of that nation, to which, though victors in the field of warfare, the Romans felt their inferiority in the more peaceful domain of literature. His preferring the wilder and more homely of Homer's poems to his more imposing, elaborate, and dignified performance, only showed that he rightly apprehended the tendencies of an infant taste. Children as they were in poetry, the power of the marvellous had attractions for the Romans, which that of simple yet heroic truth would probably not have possessed. The efforts of Andronicus to diffuse a taste for Greek literature did not stop here; for he was the translator also of several specimens both of the tragic and the comic drama of Greece.

Ennius.

He was succeeded by a Roman poet of original though coarse and unequal genius, Ennius (239 B. C.). Yet, with strong originality of mind, he was a worshipper of Greek literature; and his influence on his successors is probably owing in a higher degree to what he transplanted from the soil of Greece, than what he reared from the independent stores of his mind. He attempted by turns, epic, tragic, satiric, epigrammatic, didactic, and even acrostic poetry. He versified the Roman Historical Chronicles, a poem of which few specimens survive, but these calculated to excite much regret that a work, executed with so much force and feeling in parts, should have been irrecoverably consigned to oblivion. His vigorous and forcible style, with all its rudeness, conceits, and ridiculous jingles, appears in its better parts to have possessed great charms for the best judges of diction at an after period; for we find that Virgil, Lucretius, and Ovid, and particularly the first, have availed themselves most liberally, not only of the ideas, but of the precise expressions, and frequently whole lines, of Ennius;[1] while Horace, who seems to have had a warm feeling of the poetical fire that lay under the rude crust of the verses of Ennius, after citing two of his lines, says that the "disjecta membra poetæ would appear visible," however their arrangement might be transposed; a result which, he fairly admits, would not be the case with regard either to the satirical works of Lucilius or his own.

Plautus and Terence.

Neither in Ennius, however, nor in his dramatic successors, Plautus (died 184 B. C.) or Terence (born 195, died 159 B. C.), do we meet with much that is truly national. In all we are in fact perusing Greek compositions in Roman forms; for the plays of Plautus and Terence present to us, not the aspect of Roman life, but the state of Greek society, pretty much as it had appeared in the days of Menander. In the former we perceive more vigour, more variety, broader humour, but at the same time more coarseness; in the latter a limited invention, and characters reducing themselves to a few limited classes, generally an over-indulgent father, a profligate son, a rapacious mistress, and a knavish slave; to which Plautus is fond of adding some Bobadil or parasite, by way of relief. Yet in Terence's case we perceive the traces of genius, notwithstanding the close imitation by which he is fettered. His characters have a truthful air, his dialogue is always free from affectation, and sometimes touching and tender in the highest degree. In fact, a few of his best passages in this style are models of apparently artless and yet consummately artful and beautiful expression.

Lucretius.

Two other individuals of distinguished genius precede what is called the Augustan period of Roman poetry, Lucretius and Catullus; the one the most distinguished of the Roman didactic poets, the other unequalled in the short and tender lyric. Lucretius contended with an absolutely unmanageable subject; one which, from its unimaginative character, from the dreary details, psychological, meteorological, geological, which it necessitated, the inherent feeling of discomfort which it leaves behind, and the irreligious character of the opinions which it involves, necessarily interposed the most formidable difficulties in the way of the poet, which it is no disgrace even to the most distinguished genius, and such Lucretius possessed, not to have entirely overcome. It is, in fact, the highest proof of the ability and genuine inspiration of Lucretius, that he has infused a poetical vitality even into the dry bones of that philosophical mummy which he was attempting to animate; that he has treated with a feeling of poetical enthusiasm the coldest and most heartless of all creeds, the Epicurean; so that the very strains which he has employed in combating the belief of the immortality of the soul, bear upon their face the stamp of immortality. "In inspiration and in sublimity," says Frederick Schlegel, "he is the first of Roman poets; as a painter and worshipper of nature, he is the first of all the poets of antiquity whose writings have come down to us."

Catullus.

In Catullus the Epicurean theory, which wears a majestic aspect in Lucretius, appears in a less dignified but more probable form. *Carpe diem* is the motto which might be inscribed over all his compositions; yet with this enjoyment of the present mingles not absolutely a melancholy, but a pensive feeling, which gives a peculiar interest to them all. For compositions of a higher mood and more extended plan, Catullus apparently had as little ability as inclination; his taste was Grecian, and formed in the school of Alexandria; slight performances, epigrams, elegies, little lyric effusions expressive of individual feelings, like the charming lines to Sirmio, or the lament for the sparrow, and polished with the most exquisite felicity of diction, were the subjects to which his talents were devoted. There is, in fact, every reason to believe that his more ambitious performances, such as the Epithalamium of Peleus and Thetis, and the Atys, were simply editions in a Latin form of Greek originals.

The poets hitherto mentioned belong to the period of the republic; in their successors, the poets of the Augustan period, we perceive a considerable change both of spirit and expression. Under the calm but firm sway of Augustus, which had reduced all the contending parties under one powerful dominion, and conferred upon the country the blessings of peace, the art of poetry was peculiarly cultivated and patronized. And it is at this period that the Roman poetry first displays in its fullest extent that feature which Frederick Schlegel considers its truly national and original trait, namely, that exaltation of Rome and of the Roman character; that feeling of the unrivalled energies, the rapid growth and ever-increasing dominion of their country, which formed, to the imagination of the poet at least, an ample compensation for the loss of that liberty which, since the commencement of the troubles of the Gracchi, or the contests of Sylla and Marius, had been little better than a political phantom, or a party watchword with no real meaning.

Virgil

The great representatives of this Augustan period of poetry are Virgil and Horace. No two poets could be more dissimilar in the direction of their tastes, and yet it would be difficult to say to whom the palm of greater genius ought justly to be assigned. Even in his Pastorals, though an early work, the leading qualities of Virgil's mind, his exquisite taste and fine sensibility, are apparent, though they can hardly be considered in any other light than as graceful adaptations, and, it may be safely added, *improvements*, of the subjects and manner of Theocritus. In these he was painting from a painting; he was copying a Greek landscape in the colouring of the Latin tongue. But in his Georgics he drew from his own observation of Italian nature; and, bringing the native excellencies and qualities of his mind to bear upon imagery and events and associations which nature and experience had dictated, presenting us with delicious landscapes varied by all the natural occupations of the Italian agricultural life, gilded by sunshine, clouded by storm, or darkened and disturbed by tempests; combining these in the most dexterous manner with striking allusions to well-known events and catastrophes of Roman history, such as the prodigies which portend the death of Cæsar, or with old mythological traditions; and making the driest details of husbandry, such as the grafting of trees or the breeding of bees, prolific of imagery or of fable consecrated by early associations; the result is one of the most original and at the same time delightful poems which exists.

---

[1] Dunlop, History of Roman Literature, vol. i. p. 21.

The Æneid was a great, but, it must be admitted, unsuccessful attempt to do that for Rome and the Roman people which Homer had done for Greece, namely, to give the Romans a great national poem. No one felt this failure more than Virgil. His reluctance to give publicity to the Æneid is well known. He could only be prevailed upon to read to Augustus the first, second, fourth, and sixth books. Several causes may be obviously assigned for its want of success. 1*st*, Not only did Virgil, from the intense admiration he felt for Homer, copy in many respects his characters and design; but he endeavoured to combine the distinct and almost incompatible characters of the Iliad and the Odyssey, the grand and warlike character of the former with the wandering and adventurous character of the latter poem. 2*d*, Although the notion of grafting the adventures of Æneas upon the origin of the Roman nation, was in itself a happy one; and the mythological traditions connected with it might have been brought to bear with much effect upon the subject; Virgil committed the great error from which Tasso has also suffered, of making an epic poem a mere instrument of political flattery, by identifying the character of his hero with that of Augustus. By depriving himself of the open and untrammelled field which the traditional character of Æneas presented, and making that character a mere portrait, *en beau*, of the cold-blooded, calculating, and critical emperor, he lost at once all hold over the sympathies of the reader in the fortunes of his hero, a cardinal point in all poems that pretend to the character of epic. 3*d*, Nay, he even enlisted those sympathies against him; for, as Voltaire, who is seldom wrong in what may be called the logic of poetry, observes, he represents him as a mere adventurer, who in the first place is guilty of the most shameless want of feeling in regard to Dido, whose sole object is to acquire a settlement in Italy; who, in breaking off the match of Turnus with Lavinia, is instigated, not by passion, but by policy; and who would in all probability have most willingly surrendered the Latian princess to his brave and generous though cruel rival, if *he* would have resigned the kingdom of Old Latinus to a Trojan stranger, and taken Lavinia, like Cordelia, without a dower.

Only one substantial addition has been made by Virgil to the characters of Homer, and for that character he may have received some hints from the Ariadne of Catullus; but it must be admitted to be one of the most deeply interesting in poetic fiction, we mean that of Dido. The great night-picture of the sack of Troy, and the episode of Dido, are indeed the finest things in the Æneid. In the character of the Carthaginian princess, we perceive the infinite advance which the delineation of the passion of love has made since the time of Homer. Virgil has begun to comprehend that feeling, with the world of emotions to which it gives birth. And if he has not painted it with all that purity and depth which was imparted to it by Christianity, he has exhibited its leading traits with a warmth and sensibility which make all the other classical delineations of passion both cold and lifeless beside that of Dido.

Horace.

Horace exhibits the singular specimen of a poet borrowing half his thoughts from the lyric writers of Greece, and making his odes a mosaic formed from the gems of other countries as well as his own, and yet imparting to the combination a high degree of unity, and a decided originality of character. Calm wisdom, shrewd penetrating observation of life, a sober enthusiasm, and most refined taste, are the qualities which most distinguish him, imparting to all his compositions extreme point, terseness, and occasionally, in themes of a higher cast, particularly those connected with the elder worthies of Rome, or the lofty position she then occupied in the eye of the world, a stately and solemn grandeur. This admirable balance of mind which distinguishes Horace, and informs all his writings with such pregnant good sense, renders him a peculiar favourite in a country like our own, whose national character is marked by not a few of those features that distinguished the mind of the poet. Hence his odes are more read and quoted, particularly by men of business and practical sagacity, than the works of any of the classic poets.

But the merits of Horace, though most conspicuous as a lyric poet, are great also as a satirist. Lucilius had indeed made the first approach to the regular form of Roman satire; but his rude and harsh effusions can no more be compared to the polished and graceful productions of Horace, than the rugged verses of Donne can be compared with the satires and epistles of Pope. In Horace all follies and lighter vices of the day (for he seemed to think satire scarcely a fit weapon when directed against the darker vices) are touched on in a strain of the most urbane ridicule, which insinuates reproof. As compared with those either of Lucilius who preceded, or of Persius and Juvenal who succeeded him, the tone of the Horatian satire is light and playful. It has been correctly observed, that these satires filled up for Roman literature exactly the department which in our times is occupied by the stage. For as the plays of Plautus and Terence truly represented Greek and not Roman manners, it was in the light form of satire that all those humorous follies and oddities of Roman society, which properly fall within the range of the comic, were displayed and exposed.

The elegiac poets.

The elegiac poets of this period, Tibullus and Propertius, wrote with purity and good taste; the former with more of tenderness, the latter with more of force and mental vigour. But in the extravagant luxuriance and frequent conceits of Ovid, we perceive the commencement of that decline of poetry, which, relieved only by the manly vigour of Juvenal's satires, goes on in rapidly-increasing progression to the extinction of the Roman empire. For the amatory and elegiac poems of Ovid little can be said; they want heart and passion as much as delicacy or propriety of sentiment. But the praise of a teeming fancy cannot be denied to him; he is a mine from which thoughts and expressions may be dug without end; and his Metamorphoses, as a graceful exposition of the finest mythological tales of antiquity, will always retain their interest for modern times.

Juvenal.

We pass over the so-called tragedies of Seneca, the works of a mere school rhetorician; and the satires of Persius, obscure and rugged, though not without a masculine energy. But the name of Juvenal must be mentioned as the last great poetical name that illustrates this period of decline.

In the finer portions of his satires, for it must be admitted they contain a good deal that is level and prosaic enough, he displays the highest talents for this species of poetry; the strength of his language, the fire of his invective, correspond with the gigantic character of the vices which he exposes. But a certain air of exaggeration mingles with and alloys the effect of his censures; we are led to think of the doubtful character of his own life, and to question the title of the moralist to raise the scourge which he applies with such severity to others. A tinge, in short, of that rhetorical and formal character which his mind appears to have contracted in the schools of declamation attaches to his poetry, and leaves an impression of hollowness and insincerity upon the mind.

Lucan.

Lucan's Pharsalia, it must be recollected, was a comparatively boyish effort; but it seems plain, from the character of his mind, that he wanted the highest of the poetical faculties, imagination. He uttered bold and striking thoughts occasionally in the happiest words. No poems afford finer specimens of single lines for quotation than Lucan. But the whole is destitute of poetical warmth; it blazes only with a phosphoric fire. Quinctilian has, in fact, hit with admirable tact the character of Lucan's mind in the remark, "Si dicam quod sentio, oratoribus magis quam poetis annumerandus."

We shall not here touch upon the remaining writers who feebly kept alive the vestal fire of poetry up to the period of the overthrow of the Roman empire of the west; Statius, Claudian, or Ausonius. Even the introduction of Christianity, much as it did towards improving morality, not only among its votaries, but amongst the Pagan nations themselves, could not re-animate to new life the worn out and enervated frame of literature. That could only be effected by sweeping away entirely the old landmarks, making a new heaven and a new earth, creating new associations in all the ideas of men, giving them new hopes, aspirations, and pursuits, and thus restoring that elastic principle of moral and mental vigour, of faith and enthusiastic feeling, out of which all high poetry must spring. From the rude but warlike and uncorrupted nations of the North. was to come that influence which was to give a new aspect to society; at first, like the descent of a deluge, sweeping the remains of cultivation before it, but ultimately depositing and carrying deep into the bosom of the soil the elements of a reviving and healthy fertility.

POETRY OF MODERN EUROPE.

From the fall of the Roman empire of the West, about the close of the fifth century after Christianity, to the appearance of the first great poet of modern Europe, Dante, an interval of seven dreary centuries elapses, a period characterized in popular language by the epithet of the dark ages. During this period the chaos resulting from the overthrow of the old Pagan constitution in religion, government, laws, and social institutions, was gradually settling into shape; the new religion was incorporating itself with and imparting a new form to social life; new laws superseding the subtile and complex jurisprudence of Rome, new languages growing out of its ruins. During the greater part of the period to which we have alluded, literature, in any high sense of the word, did not exist; but the materials of new literatures were accumulating, and the spirit which was to give them breath and vitality, when language should be sufficiently settled for the purpose, was in the course of development, though manifesting itself in other fields and departments than that of poetry. When poetry re-appeared in the thirteenth century, the influence of the intermediate changes which the human mind had undergone became visible in certain marked traits, separating by the broadest distinctive lines the character of the modern European from the ancient classical poetry. A few of these, as applicable to all the modern literatures of Europe, though with differences in degree, may be indicated before proceeding to any notice of these separate literatures.

1. The first and most important is the influence of the Christian religion on the productions of the imagination.

The Pagan religions were mere religions of the fancy; they were nothing but the poetry of humanity. They dealt only with the palpable and the material; and by the combination of the finest features of the actual, they produced an ideal which each moulded to his own fancy. The conceptions of the infinite and the immaterial they avoided. The solemn and the mournful found no place in their thoughts, or, if such ideas did intrude, they were made use of as arguments for present enjoyment. Let us eat and drink, seems the moral of paganism; let us eat and drink, for to-morrow we die.

From this materialism of the ancient mythology, and its purely imaginative character, the results were, 1*st*, great clearness in all its conceptions and its expressions, that clearness which is imparted by the absence of all that is not palpable to sense; 2*d*, a light and cheerful tone, the natural product of that mental indifference, and absence of serious reflection, which the disbelief, or as least doubt of immortality, would produce; 3*d*, the feeling of *beauty* as the object aimed at and accomplished, and the vital principle of all the classical creations.

Very different were the character and the influence of Christianity. This was a revelation, not a creation of the fancy. It spoke to the heart, to the hopes and fears of men, not merely to their imaginations. The outlines of the Christian theology were communicated in a fixed and settled form, with which fancy could not deal at will, or mould them in accordance with its notions of beauty. It excluded at once that plastic power which had formed the excellence of Greek art and literature, and banished mere *beauty* as the aim of the poet, or the principle of modern inspiration.

To the clearness, the sunny lightness of touch, the cheerful levity of tone, which distinguish the classic poetry, it was equally unfavourable. It made the mind familiar with the ideas of infinity and eternity; it accustomed it to abstract conceptions beyond the pale of sense, or the scope of distinct expression; it forced upon its consideration the immaterial and the invisible, as constantly as the Pagan theology had confined the attention of its votaries to the visible and the actual. The Pagan clearness of portraiture, and smiling lightness of tone, were incompatible with the description of regions and states of being, sights and sounds, which eye had not seen, nor ear heard, and which it had not entered into the mind of man to conceive. The Christian poet, before whom, instead of a natural and visible Olympus and Acheron, there stretched out in dim but awful vision the conception of heaven and hell, encompassed by an eternity on this side and on that,—a conception impressed by the sense of moral responsibility, and of eternal punishment or happiness, and animated by a principle of faith based upon things not seen,—could not but carry into the literature which was the expression of his thoughts, and hopes, and fears, some shadow of that solemnity and mystery with which human life was now surrounded. He left this narrow spot of earth, already in the possession of his predecessors, to open up the new and undiscovered country of the abstract and the invisible; and the principle of poetical inspiration which they sought in beauty, he found in *grandeur* and *sublimity*. Hence earnestness and profundity are the means of effect in the literature of Christianity; and elevation rather than beauty may be said to be the aim of the higher poetry of the moderns.

2. The superstitions which grew out of the corruptions of Christianity, and which assumed a systematic form after the crusades had opened to Europe a communication with the East; the belief in spectres, fairies, witchcrafts, and the di-

rect interposition of evil spirits in the affairs of men; gave a different character to the modern literature of Europe. It is true, that in the Canidia of Horace, the Erichtho of Lucan, the Thessalian scenes of enchantment in the Golden Ass of Apuleius, and occasionally in other passages of the classical writers, we have allusions to popular superstitions somewhat analogous to our own; but it is equally plain that these are not matters of serious belief, but of poetical embellishment. They could not, in fact, cohere with any consistency with the framework of the antique materialism, though they might be combined with a religion which assumed the existence of powers unknown to human sense, and of a principle of evil, which, with limited powers, was permitted to oppose the principle of good. These conceptions of immaterial beings distinct from men, but influencing their actions, assumed a reality and appearance of probability, which soon rendered the belief in their existence one of strong practical influence upon society, and of course upon literature. Hence the gloomy and superstitious character impressed upon many of the earlier productions of all nations; and which, during the fifteenth, sixteenth, and seventeenth centuries, manifested itself in such fearful action in the atrocities of the trials and executions for witchcraft.

3. Whilst the Pagan mythology affected only the imagination, Christianity appealed to the conscience, and was calculated to operate practically upon conduct. We see, accordingly, in the history of the middle ages, that religion was not, as it becomes in after ages, a mere profession. often assumed from habit, but a principle of faith, of conviction, and of serious action. We see, through this invisible but powerful agency, a spiritual throne established at Rome, to which, weak and insignificant as it appeared in physical and economical resources, the most powerful monarchs in Europe were content to bow with implicit obedience. During the middle ages, the possession of the keys of St Peter was found a more effectual instrument of supremacy than the temporal sword. We perceive the clergy looked upon as a superior race; their persons and possessions considered as sacred; the rudest and boldest nobles of the time trembling at the thought of their anathemas, courting absolution at their hands, soliciting dispensations, founding monasteries and cathedrals, undertaking penances, pilgrimages, and crusades; and we see them often, in the midst of the fierce career of warfare, as if struck by some sudden inward but irresistible impression, throwing down the sword, exchanging the helmet for the cowl, and wearing out, as is told of our own Guy of Warwick, the evening of a stormy life in the peaceful cell of the hermit. There was in all this much of error, much of impure feeling and doubtful character; but there was also much of truth, much of earnestness; and hence faith and devotion are as visibly stamped upon the literature of the middle ages, as they unquestionably were influential upon its life.

4. Apart from the influence of religion, although not unconnected with it, there were other social changes which had strongly affected the course of feeling and opinion, and could not fail to render themselves visible in literature as soon as it began to assume a regular form. The most important of these was the institution of chivalry, growing out of, and affording an imperfect remedy for, the defects and evils of feudalism; an attempt, in fact, to create a species of police or constabulary, founded upon those principles of generosity and honour which were frequently found associated in the human mind with cruelty or licentiousness, during those stormy days of feudal dominion.

It was not, however, on its warlike and serious side that chivalry exhibited any very novel features; for, as far as regarded merely its spirit of adventure, numerous parallels might be found in ancient story to the exploits of its votaries. The feats of Theseus with the Minotaur, the story of Perseus's deliverance of Andromeda, the Argonautic expedition of Jason in search of the golden fleece, the more celebrated expedition against Troy, all closely resemble the exploits which chivalry prescribed to the members of its order. The true point of view in which chivalry gave a new direction to the opinions of the age, and a new impulse to literature, was in the altered position which it gave to women. It is certain, that before chivalry was known, nay, before Christianity was introduced, a peculiar reverence for women had been shown by the Gothic nations. Tacitus, in his treatise on the manners of the Germans, adverts to this as one of their characteristic features. "Inesse iis etiam *sanctum aliquid* et providum putant." The introduction of Christianity ratified and consecrated this feeling of respect. It made woman the equal and companion, not the slave, of man. But chivalry went a step farther. It reversed the relations in which the sexes had stood during the classical times, and exalted, in theory at least, the softer sex above the stronger and the more warlike. As the best means of arming the helpless against the powerful, it surrounded them with an angelic atmosphere of sacredness, and converted love into adoration, respect into religion. Here, too, there was something affected, but much more that was genuine. This feeling, exaggerated as it seems to us, did unquestionably influence in a high degree the opinions of the age, their tastes, their modes of expression. Its effect upon modern literature has been most remarkable. It has rendered the principle of romantic love almost the mainspring of modern poetry, and of imaginative composition in general. It forms almost the sole subject of the poems of the Troubadours, the minstrels of the south of France, Spain, and Italy, with whose compositions the history of modern poetry properly commences. Dante, the father of the Italian language and poetry, finds the source of the inspiration which dictates his sonnets and canzoni, and at last the *Divina Commedia* itself, in this species of romantic adoration for a deceased mistress. Petrarch's poetry, and his deification of Laura, are one and the same thing. The lyric poets of the fifteenth and sixteenth centuries of Italy seem to have scarcely conceived that any other course than that of imitating Dante and Petrarch in this chivalrous Platonism was open to them. The principle of romantic love is carried by Pulci, Boiardo, and Ariosto to an excess which communicates to it an air of the ludicrous; a reproach, however, from which it is again redeemed by the serious and enthusiastic Jerusalem of Tasso. When in modern times the attempt was made to revive tragedy, it proved totally unsuccessful, until this principle was admitted into the drama to give it warmth and life. Of that species of composition which in its proper sense is peculiar to the moderns, viz. the novel and romance, it forms, as we all know, the moving power. In short, it influences, more or less, every department in which the imagination has exerted itself with success since the revival of literature.

5. Another point in the social institutions of the time, which affects in a considerable degree the spirit of the literature of the European nations in the outset, is the relation of feudal vassalage, the degraded condition of the mass of the people, and the subdivision of the state into so many separate baronies, within each of which its feudal lord exercised supreme authority. This subdivision annihilates that inspiration of *patriotism*, or attachment to country or state, which is very visible in the Roman literature, and more faintly in the Greek, and introduces in its stead the principle of *loyalty* or implicit obedience to the individual superior to whom fortune had given the right of disposing of the destinies of his vassal. Submission to authority under all circumstances, without remonstrance, is represented as the highest of virtues; and a violation of this principle cannot be palliated by any exhibition of courage or self-devotion. A fine illustration of this principle in the moral code

of the feudal times occurs in Schiller's fine ballad of the Fight with the Dragon, founded on a story given as authentic by Vertot, in his History of the Knights of Malta. Rhodes was laid waste by a monstrous serpent, which has already destroyed not a few of the knights of St John, who had been rash enough to engage in combat with it. The grand-master, accordingly, had strictly prohibited any of the order from engaging in the apparently hopeless attempt. One young knight, unable to witness with patience the spectacle of the misery and distress daily caused by the ravages of the monster, ventured to despise the prohibition, and, by dint of art and valour combined, delivers the island from its persecutor. He was conducted in triumph to the hall, where the knights were met in council. The grand-master received him in gloomy silence, reminded him that *obedience* under the Christian creed was the first of virtues, and banished him from the island. The knight, conscious of his error, bowed in silence, divested himself of his knightly mantle, kissed the hand of the master, and was about to go. The stern superior was softened; he called him back, and, presenting him again with his sword and mantle, informed him that his prompt submission and penitence has restored him to the rank which his disobedience had forfeited.

6. One other feature is strikingly characteristic of the earlier literature of Europe, although good taste at a later period has pretty well weeded out its traces, viz. the singular and incongruous mixture of science with poetry. The literary men of the time were learned men, familiar with theology and with the writings of the ancients, and delighted with the abstractions and refinements of a mystical theology and a scholastic logic; and that which interested them in reality, they unconsciously incorporated with their poetry. This tendency tinges the whole Italian poetry, from Dante to Ariosto. Petrarch, even while singing of love, cannot allow the subject to pass without some learned and complimentary allusions to Aristotle. The Spanish lyric poetry of Boscan, Garcilaso, and their successors, is a sort of versified Platonism. The verses of Ronsard, and the other worthies composing that poetical constellation which arrogated to itself the name of the Pleiades, are so full of learned allusions as to be absolutely unintelligible; and the influence of this somewhat pedantic exhibition of ancient literature is undeniable even in our own Milton.

Poetry during the middle ages.

Having premised these remarks on some of the characteristic features of distinction which separate the religious, reflective, warlike, and mystic poetry of modern Europe, from the airy, graceful, and transparent spirit of the classical, we may observe, that although, as we mentioned, nearly seven centuries elapsed before the appearance of any poet of permanent European reputation, poetry was not entirely idle during the intervening period; but, on the contrary, towards its close at least, in a state of high activity and fertility of production. Scarcely, indeed, had the different languages of Europe begun to arrange themselves into form, before poetry in a rude form made its appearance. Most probably in Germany the cradle of the modern poetry of Europe is to be found. By the time of Charlemagne, it is certain that country contained a vast mass of legendary poetry, which was carefully collected, committed to writing by the directions of the emperor, with a view to preservation, but of which scarcely a traditional fragment now remains. Earlier than the time of Charlemagne (A. D. 740 to 814), in all probability, were the lays of the Nibelungen and the Heldenbuch composed, though they have descended to us only in the altered form given to them when recast by Henry of Afterdingen. The former carries back its scenes to the days of Attila the Hun; and in truthful simplicity and vividness of painting, its homely and nervous verses are even yet worthy of admiration. A fund of bold and rich invention is, in like manner, displayed in the Sagas of Scandinavia, the mythology of which, at a later date, came to exert a strong influence over the poetry of Europe.

Provençal.

The Provençal language, the first-born of European tongues, in which Thebaut afterwards sung, and Cœur de Lion expressed his complaints in prison, we find moulded into form about the close of the ninth century. The Provençals had undoubtedly borrowed many things besides rhyme from the Arabian literature of the Peninsula, for an oriental spirit is visible in many of their compositions and much of their imagery. But, on the other hand, they added much from their independent stores; they widely extended the domain of poetry, gave it spirit as well as refinement; they even rendered it, as Villemain observes, a substitute for the liberty of the press; while their forms of versification, canzoni, sonnets, sestine, madrigals, &c. soon became the patterns adopted by all the southern languages of Europe. Their compositions, introduced into Germany through the Hohenstauffen emperors, instantly communicated a marked impulse to German poetry: the numerous band of the Minnesingers of the twelfth and thirteenth centuries are, in fact, the Provençals of Germany.

Trouveres.

In the north of France, again, arises, during the same period, the literature of the Trouveres; a literature of satires and legends, and tales of knavery, licentious gallantry and adventure, destined afterwards strongly to influence the direction of the genius of Boccacio, and his successors the Italian novelists, and to furnish the amplest materials for later writers of fiction. Nor during this creative period were fictions of a higher cast wanting.

Three cycles of legendary romance.

Three leading cycles of romance may indeed be pointed out, which owe their origin to this period. The first consists of the legends of Gothic, Frankish, and Burgundian heroes, during the times of the great northern emigrations, of which the Nibelungen and the Heldenbuch are the depositories; legends breathing a purely northern spirit, and generally having some foundation in history: the second, those which embody the traditions as to Charlemagne's wars against the Saracens, the achievements of his court ot Paladins, and the "dolorosa rotta" at Roncesvalles, where he is represented as perishing with all his peerage. In some of these Charlemagne is strangely represented, not as a most warlike and energetic monarch, but rather in the garb of a lazy and luxurious eastern sultan; a perversion of historical truth which, Frederick Schlegel thinks, must be accounted for by the poems which refer to the emperor having been chiefly written by Normans, who drew their notions of Charlemagne from some of those faineant monarchs of their own days, whom they saw in possession of his throne. It is certain, at all events, that the legends connected with Charlemagne soon became largely interwoven with incidents of a comic cast, and with a mass of absurd and fantastic machinery. The third class of romantic traditions then first embodied in poetry are those relating to the fabulous Arthur, "begirt with British and Armoric knights;" by far the most interesting of which is the celebrated legend of a pathetic and elegiac character, which bears the name of Tristan or Tristram. "Among all the great and epic poems of love and chivalry in the middle ages," says Frederick Schlegel, "the first place is given by all nations to Tristram; but that we may not be fatigued with uniformity of fiction, the airy and lively legend of Launcelot is placed by the side of its more grave and elegiac representations." He traces also in these legends of Arthur and the Round Table a double purpose; an allegorical character, viz. an attempt to shadow forth the ideal of a spiritual and Christian knighthood, imparting to them in general a higher character than to the corresponding traditions of Charlemagne.

The Monkish hymns.

One other class of the compositions of the middle ages may be alluded to, their monkish hymns, written in Latin, that is to say, the bastard Latin of the period, and generally in rhyme. They cannot indeed be praised for their novelty of thought, or high imagination; but their earnestness of purpose, whether in describing ideas of terror or pity, and which was the expression of one belief and one heart pervading many nations, give them a considerable hold over the mind. No one can be insensible to the awful grandeur of the *Dies iræ, dies illa,* which Roscommon, who translated it into English, is said to have died repeating; or the simple pathos of the *Stabat mater dolorosa,* which, even divested of the charms of Pergolesi's music, speaks to the heart. Of nearly equal beauty are the *Jam mœsta quiesce querela* of Prudentius; and the *Ave Maris Stella,* being an invocation to the Virgin, which may still be traced in the songs of the boatmen of the Mediterranean. The forcible impression made by these simple sacred hymns on the mind of Dante is obvious, from the manner in which lines or portions of lines from them, are here and there woven into the *terza rima* of his great poem.

It cannot therefore be said that the middle ages were an unpoetical period. On the contrary, there was then a very general diffusion of poetic feeling. But the poetry to which it gave rise was not marked by any of those works of excellence rising conspicuously above the rest, which attract attention to the names of the authors. Its productions are chiefly anonymous; its poets have died and made no sign. A great genius was still wanting to form an epoch in the annals of poetry; but that genius was found in Dante, about a century after the Tuscan dialect had assumed a predominance over the other dialects of Italy.

ITALIAN POETRY.
Dante.

The Divine Comedy of Dante (born 1265, died 1321) is the first work of distinguished and original genius which graces the literature of modern Europe; and it is in many respects a most striking and remarkable production. It is not, as the name would import, a drama; as little does it resemble an epic poem; it is an allegorical pilgrimage through heaven, hell, and paradise, which the poet has peopled with human shapes, human passions and crimes. He has made his poem an instrument through which he vents his political loves and hatreds, his vast and undigested learning, his scholastic acuteness, his mystical philosophy, his reverence for the ancients, his sympathy with the spirit of freedom, the enterprise, the enthusiasm of the moderns. It resembles, in fact, the Homeric poems in its encyclopædiac character. The poet stands, as it were, on an isthmus, from which he can cast back his glances across the tumultuous and still heaving chaos of the middle ages, into the serener regions of the past, and forward into a futurity of which he foresees and foretells the coming glories. Many, no doubt, had been the allegorical compositions which went before him; the Roman de la Rose, indeed, still survives, in the translation of which Chaucer wasted so much of his earlier powers; but all have been thrown into shade, and it may be said effaced, by the grasp, magnificence, and sombre power, combined with deep human feeling, of the great allegorical pageant of Dante. For in this last quality, quite as much as in the attributes of sublimity and grandeur, which are universally conceded to him, lies the secret of that perennial charm of freshness which still gives interest to the *Divina Commedia.* Amidst the darkest scenes of infernal punishment some soothing objects or images are constantly introduced to lighten our pilgrimage, and flowers are made to spring up beneath our feet, as if to freshen the path "over the burning marle." His wearisome metaphysics have long ceased to please; his mystic raptures, his pictures of the celestial occupations of the saints, appear almost ludicrous; his demons and his Satan grotesque rather than impressive: but the deep pathos of the story of Francesca of Rimini; the thrilling scenes in the tower of Hunger; the few simple lines which tell the story of Madonna della Pia, imbibing a slow but certain death among the swamps of the Maremma, to which she is consigned by a jealous husband; the sweet apostrophe to evening, and the fireside recollections which the sound of the vesper-bell brings along with it: these and such episodes are the passages which linger in the memories of all, and give to the poem of Dante its main hold over the heart.

The imagination, on the other hand, is singularly roused by the scenes of torture and bliss through which we are led, the burning tombs, and cities alive with flame, and valleys of the shadow of death, where serpents torture their victims, and the ever-deepening descent through the circles of hell, contrasted with the cheering light which begins to break upon us in the ascending circles of purgatory, and the refulgence of the visions which greet the wanderer on his entrance into paradise, when he exchanges the guidance of Virgil for that of Beatrice.

Distinct as the imagery in the foreground is, the prospect fades away on all sides into the illimitable, and the imagination has full room to expand itself in the sphere of the mysterious and indefinite. Dante's poem may, indeed, be well compared to that "wild and hoary wood" in which he describes himself as losing his way in the outset, with here and there a path cut through the trees, where the sunshine pours in and shows spots of verdure or still waters, but backed on all sides by dusky labyrinths, inhabited by beasts of prey, into the gloom of which the eye can hardly pierce, and the immemorial stillness of which the sound of human footsteps has never broken.

The style of Dante's poem is scarcely less remarkable than its spirit. Obscure and unyielding, as might be expected, in some parts, it has, nevertheless, a picturesqueness without parallel in modern literature. It makes every object palpable or sensible; flashing images upon the mind with the rapidity and the splendour of lightning. "They are," says Ugo Foscolo, "the bold and prominent figures of an alto-relievo, which, it seems, we might almost touch, and of which the imagination readily supplies those parts that are hidden from the view." It fixed the Italian language, so that at this moment it remains less changed since the time of Dante than any other European tongue.

Petrarch.

As Dante is the head of the Italian allegorical poetry, so Petrarch may be regarded as the founder of the lyrical; borrowing indeed his manner, and not a little of his matter also, from the Provençals, but by a refined taste acquired from the deepest study of the classic poetry, and a sensibility, the liveliness of which was quickened by a real passion, investing their strains with a character of tenderness and perfect finish, which really appear to confer on them a different character. The monotony disappears of which we are conscious in reading the compositions of the Troubadours and Minnesingers, "qui toujours d'un même ton semblent salmodier;" and a wonderful variety of emotions are seen to arise out of a theme which, in their hands, had appeared limited and barren. No one has ever drawn a finer poetical ideal of female loveliness, purity, and worth, than Petrarch has done in Laura. "Every lover," says Herder, "will find *his* Laura in that of Petrarch; he will find his own heart, with all its weakness, and that beneficent influence which the female character in its purity can exert over the disposition of the youth and the man." The verbal subtilties and plays on words which disfigure many of the lyrics of Petrarch no doubt detract from their effect, and excite surprise that one whose taste was in general so pure should have given admittance to such conceits; but, like the puns and equivoques of Shakspeare's time, they were part of the fashion of the day. Petrarch found them imbedded, as it were, in the Provençal poetry from which he drew, and he yielded, like Shakspeare, to the evil influence of the time. Upon the whole, however, the services rendered by him as an Italian poet (for we need not here allude to his great and most beneficial influence on the taste of Europe, by his exertions on behalf of classical literature) have been very great; he sensibly added to the polish, grace, and pliancy, of the Italian tongue; and of the Platonic poetry of love, a love existing rather as a lambent glow than as a flame, and living on as a sentiment after it has ceased to be a passion, Petrarch still remains the purest and the most charming representative. (See the article PETRARCH.)

The Petrarchists. It is a remarkable fact, that though the genius of Dante was unquestionably far more masculine, original, and imposing than that of Petrarch, the former left no successors, while Petrarch turned for nearly two centuries the whole current of poetry into the direction of the amatory lyric. Dante was found to be unapproachable; within the circle he had formed, none durst walk but he; but the Platonism of Petrarch, and the apparent simplicity and brevity of the medium through which his tranquil and gentle inspiration was conveyed, appear to have tempted every one into imitation of his lyrics. Hence, until the fifteenth century in Italy was well advanced, its poetry consisted of little else than imitations of Petrarch. But, in truth, though this was not perceived, all the finer essence of Petrarch's poetical character was nearly as incommunicable as that of Dante; and accordingly we find, among the latter Petrarchists, that much of the delicacy and truth of Petrarch, that *feeling* which gives a tempered warmth to his expressions, and calms without chilling the heart, disappears. The raptures of love, and that struggle of passion and reason which so constantly recurs in Petrarch's poetry, are pitched in an exaggerated and falsetto key; the conceits grow more numerous as the feeling grows less intense and real; till at last, of all which their great original had produced, little is found transplanted into their imitations, save the indestructible harmony of the versification.

The fifteenth century, which followed the death of Petrarch, is fruitful in learned men, in grammarians and philosophers, but barren in poetry. The excessive cultivation of classical literature, and the admiration excited by its great models, created a feeling of distaste for Italian composition. Traces, no doubt, of a teeming fancy appear in the unfinished stanze of Politian; and the rustic and carnivalesque songs, both of the great Lorenzo and of Machiavelli, have a merit independently of the interest attached to their authorship. Machiavelli's comedy of the Mandagola has been pronounced by a competent judge to be amongst the best specimens of the comic which the Italians possess. But till the rise of that branch of poetry which may be regarded as the peculiarly national poetry of Italy, namely, the serio-comic romance of chivalry, nothing of a marked or original character appears. We turn, therefore, at once to the dawn of that school in the rough poem of Pulci.

Serio-comic romance of chivalry. There seems little doubt that feudalism, with that attendant spirit of chivalry which was born of its union with religion, never obtained any great influence in Italy. Petrarch even speaks of the warlike fictions of romance with dislike and contempt; and indeed, from the earliest periods, we can perceive the traces of a commercial much more than a military spirit; inclining the nation, in the adoption of foreign models, to turn with far greater interest to the gay, lively, and licentious tales of the Trouveres, or the dreamy reveries of the Provençal poets, than to those tales of chivalry, the "romans de longue haleine," which formed the study and the delight of the rest of Europe.

Before the period, too, when the Italians first thought of resorting to the fictions of chivalry as the materials of poetry, the feeling of chivalry itself was generally on the decline throughout Europe, and its high-flown sentiments and extravagances in action were beginning to be looked upon as a superannuated and exploded fashion. Hence the consciousness of a certain air of ridicule attaching itself to themes of this kind must from the first have been present to the minds of the Italian poets; and accordingly the chief puzzle connected with the work of Pulci, the Morgante Maggiore, is, whether the work be of a serious nature, or an elaborate jest; or whether, as seems more probable, it be not a jumble of both.

All the Italian poets who have adopted these fabulous themes of chivalry seem, in fact, to have perceived that, in their own country at least, the taste for romance, if it ever existed, had gone by, and that a serious poem, in the style of the prose romances of chivalry, would have met merely with ridicule or neglect. Their aim, therefore, seems to have been to avail themselves merely of the fictions and machinery of romance, as affording a new source of poetical embellishment; to address no higher feeling than the principle of curiosity aroused by complicated adventure; and to anticipate, by a tone of levity, and a gaiety approaching to the comic, that ridicule with which they felt that the spirit of chivalry had begun to be associated. They wrote "as if they mocked themselves, that could be moved to *sigh* at any thing." This aim is visible in them all; they differ only in the degree of art, taste, and genius with which the result at which they aimed has been accompanied.

Pulci. In the rude poem of Luigi Pulci (born 1431, died 1487), there is no harmony whatever between the extremes of the tragic and comic. The poet appears to be in one page sincerely devout; in the next he seems a profligate and scoffer. The broadest farce in the adventures of the good-natured but stupid giant Morgante, alternates with the elevated and the pathetic in the really chivalrous enthusiasm of the battle of Roncesvalles and the death of Orlando; the dreariest platitudes are succeeded by occasional outbreakings of devotional enthusiasm or fine sentiment. The effect of the whole is disjointed and painful, and such as to excite our surprise that the accomplished companion and favourite of the great Lorenzo should have produced a work so enigmatical and unsatisfactory.

Boiardo With more invention and greater variety than Pulci (for in the construction of plots, and in sketching the outline of characters, Boiardo left little for Ariosto to perform), and with far less of that disposition to caricature in which Pulci unconsciously indulges, the *Orlando Innamorato* of Matteo Maria Boiardo (1430 to 1494) still wants that airy grace and ease of movement, that unconscious flow, like the marvellous tale of an Arabian improvisatore, without which this species of poem,—a "chartered libertine," in as far as regards the ordinary canons of criticism,—can have no permanent success. In Boiardo's hands it moves laboriously and stiffly; his verse wants harmony; his style wants pruning, polishing, and lightening. This, together with the infusion into the poem of a most peculiar species of grave humour, was the service afterwards performed for Boiardo by Berni, with such perfect success, indeed, that the *rifaccimento* has superseded and almost obliterated the recollection of the original.

Ariost It remained, however, for Ariosto (1474–1533) to hit the happy medium between the *poco meno* and *poco piu;* to blend the tragic and comic in the proper proportions suited to the serio-comic epic; to give life and natural movement to the mere machines of his predecessors; to throw over his recitals an air of simplicity and *bonhommie*, which gives probability to the wildest marvels; and to invest the whole airy tissue of romance, with a style, the peculiar charm of which, though most clearly felt, appears almost indescribable; so clear, so popular and translucent, as to charm the most uneducated; so correct and classical as to satisfy the most critical taste. To compare Ariosto to Tasso as a poet of feeling, is to compare objects absolutely disparate, and unsuited to comparison. Probably the native cheerfulness and easy temper of his mind was not consistent with strong emotion; but it is equally clear, that the expression of strong emotion was inconsistent with his plan. To have grafted the deep and serious interests and passions of men upon so gossamer a groundwork as that which he has adopted, would have been like building an edifice of marble upon the unsubstantial basis of a summer cloud. In the department he assigned to himself he has employed the most appropriate instruments with corresponding success. After Homer, he has been, on the whole, the favourite poet of Europe. Above sixty editions of the Orlando were published in the course of the sixteenth century alone. "The Orlando Furioso," says Mr Hallam, in summing up a most just and discriminating criticism of Ariosto, in his Introduction to the Literature of Europe, "as a single great poem, has been very rarely surpassed in the living records of poetry. Ariosto must yield to three, and only three, of his predecessors. He has not the force, simplicity, and truth to nature, of Homer, the exquisite style and sustained majesty of Virgil, nor the originality and boldness of Dante. The most obvious parallel is Ovid, whose Metamorphoses, however, are far excelled by the Orlando Furioso, not in fertility of invention, or variety of images and sentiments, but in purity of taste, in grace of language, and harmony of versification."

The incongruous elements of devotion and ribaldry, caricature and tragic emotion, which had been left unblended by Pulci, which Boiardo partly rejected and partly harmonized, had received from the pen of Ariosto the last graces of which such a poem was susceptible. In him there is even a gentle pathos combined with a sort of enthusiasm of valour, which gives sincerity and elevation to the fantastic. But the serious and brooding fancy of his successor Tasso (born 1544, died 1595) could not be contented to sing, like Ariosto, "le donne, i cavalier, l'arme, gli amori," in the same light, and at times half-mocking strain. He determined to present the serious side of the romantic epic, as Ariosto had done the comic. Whether the dull "Gazette in verse," by Trissino, the Italia Liberata, in any way suggested to him the idea of a historical subject, we know not. Certain it is, however, that his earnestness of purpose, his deep and at last morbid sensibilities, impelled him to the selection of a theme where reality should give steadiness and human interest to the creations of imagination; and where the spirit of the Christian religion should be the moving principle, instead of a phantasm which played round the head rather than touched the heart. This theme he sought and successfully found in the delivery of the Holy Sepulchre by the crusaders; an event more interesting to Christianity than had been the Trojan expedition to the assembled princes of Asia; and satisfying that essential condition of a good epic, that its action, whatever its importance, shall be one springing from enthusiastic feeling rather than political motives. His poem was written while the European monarchs still flattered themselves with the hope of regaining the lost conquests of Godfrey in the Holy Land, and the glorious exploits at Malta, at Rhodes, at the Goietta, and Lepanto, showed the strength of the feeling that still prevailed "against the general enemy, Ottoman;" and dealing as it did with a topic of religious interest, placed among scenes hallowed by the most affecting recollections, and presenting the finest natural features for the pencil of the poet; admitting, from the remoteness of the period to which it related, and the faith which then prevailed, the introduction of a fabulous agency, contrasting with the impressive machinery which the Christian religion afforded, it is difficult to conceive a theme uniting more features of interest, or affording a richer or more picturesque groundwork for an epic poem.

Tasso has conceived his plan in the spirit of antiquity, and in the grand and enlarged style of the classic epic; but he has executed it in the spirit of the middle ages; and perhaps the point in which Tasso has been most completely successful, is the skill with which the spirit of a religious chivalry is breathed into the classic framework; and all the incidents which he liberally borrows from Homer or Virgil, are made to harmonize with that prevailing tone of devotion, valour, and tenderness, which is spread like an atmosphere of purity over the Jerusalem Delivered.

The episodes.

Whilst the general plan of the Jerusalem, perhaps, bears too close a resemblance to that of Homer, in the retirement of Rinaldo, like Achilles, from the army, which is made the nodus of the poem, the singular beauty of its episodes has been always felt and admitted. In fact, it is by the episodes that we chiefly remember the poem. Tasso has thrown the whole tenderness of his soul into such passages as those where he describes Sofronia and Olindo at the stake, the "pastoral melancholy" of Erminia's residence with the shepherds, or Clorinda perishing by the hand of him who would willingly have died to save her. The turn of his mind, in fact, was fully more towards the lyrical than the epic, and, in passages like these, the lyrical tendency breaks forth with peculiar force and flow.

Character.

In his characters Tasso has not made any very substantial addition to the picture gallery of the ancients, though even in this respect he is superior to Ariosto, who in most cases contents himself with a few general types without distinctive traits. Tasso's male characters, with one exception, that of Tancred, are judicious adaptations of Homer's outlines of character to other times, manners, and religious creeds. Tancred, however, is an original conception; perhaps the more striking that its outline was drawn in some measure from within; for in Tancred, the brave, visionary, melancholy Tancred, the victim of a hopeless passion, we probably see a dim reflection of the poet himself.

The same broad line of distinction which divides Ariosto and Tasso as to the conception of their subjects, may be traced in the whole details of their execution. Ariosto is throughout a painter. It is with external things that he chiefly deals; with colour, arrangement, form, and grouping, rather than with their internal spirit. But Tasso cannot paint this objectively. Every image, every feeling, as it passes through his mind, receives the stamp of his own peculiar habits of thought, and issues forth impressed with the image and superscription of his own tender and loving soul.

Pastorals and pastoral dramas.

Though Tasso is best known by his great epic, his Aminta deserves notice as the finest of those pastoral dramas which were so common in Italy in the sixteenth century and the commencement of the seventeenth. It was not indeed the earliest, for the Sagrifizio of Agostino Beccari (1510–1590) had preceded it. And even Beccari's work had grown out of those pastorals, frequently in dialogue, of which the fifteenth century was so fruitful, and of which the Arcadia of Sannazzaro (1458–1530) affords the finest example. Tasso's, however, of all the Italian pastoral dramas, is the most inspired by the spirit of poetry. The Pastor Fido of Guarini (1537–1612) certainly has the advantage of a far more stirring plot; it rouses more curiosity and attention, but it wants the charm, the truly Arcadian repose, which Tasso has spread over his Aminta. Here also, as in his Tancred, the feelings of the poet gave vivacity and truth to the poem; for it is not difficult to see, that under the disguise of Amyntas, and in the form of allusions to the joys and sufferings of the pastoral life, or invectives against that influence of rank and honour by which the natural feelings of the heart are suppressed, the lover of Leonora is pleading his own cause, or his own apology.

For an account of the Italian drama, which took its rise in the Sophonisba of Trissino (born 1478, died 1550), the reader is again referred to the article DRAMA in this work.

Bernesque poetry.

One species of poetry, which is almost peculiar to Italy, distinguishes or rather disgraces this period, viz. that mass of poems entitled Capitoli, &c. which obtained the name of Bernesque from the poet who first set the example of these specimens of reckless and indecent drollery, Francesco Berni (died about 1543). His quiet, grave humour, the host of ludicrous associations which he conjures up, and frequent felicities of expression, at first render even his ribaldry amusing; but when similar themes were taken up and hunted down by Molza, Casa, Firenzuola, and their followers, it became oppressive and revolting in the highest degree.

Filicaja, Testi, and Marini.

We now approach the period of decline in Italian poetry. The sixteenth century had been its golden period: in the seventeenth we drop at once into the age of brass, or the age of tinsel. Chiabrera (born 1552, died 1637) indeed exhibits lyric fire, and, by discarding the hackneyed and outworn form of the Italian versification of the Provençal school, and approximating to the metres of the ancients, gave a character of originality to his odes. Yet, granting the boldness of his imagery, and a certain fervour and enthusiasm, which raise his lyric poetry above the slumbrous and monotonous beauty of most of his predecessors who were of the school of Petrarch, it is yet impossible to subscribe to the excessive eulogiums bestowed upon him by Tiraboschi, who almost seems to think he had combined in Italian the graces of Anacreon with the majesty of Pindar. More impressive, more affecting, though occasionally, and particularly in his sonnets, more deformed by the conceits and exaggerations which give an evil distinction to the poets of this period, whom the Italians have branded with the title of Seicentisti, are the lyrics of the senator Filicaja (born 1642, died 1707), whose religious canzoni, particularly the noble triumphal hymn on the deliverance of Vienna from the Turks by John Sobieski, are amongst the finest specimens of this class of poetry of which Italy has to boast. In his sonnets he is less pure and less natural; even his famous sonnet on Italy is, in its second quatrain, disfigured by one of the poorest and coldest of conceits. One other name must be mentioned, as preserving a pure and classic taste amidst the general corruption which, under the influence of Marini, was now pervading and perverting the whole spirit of Italian poetry. We refer to Fulvio Testi (1593–1646), the Italian Horace, as he has been called, a title certainly quite unmerited, so far as regards the power or brilliancy of his imagination, but not inappropriate, if limited to the purity and terseness of his style. The greater corrupter of this declining period of Italian literature is the once famous Marini (born 1569, died 1625), the author of the Adone, a poem which is an absolute chaos of brilliant antitheses and exaggerated language, plays of wit and ingenious imagery, but heaped together without the slightest direction of any governing judgment, and producing a tiresome and chilling, instead of an exciting effect. In his own days his writings were differently estimated. For a time, indeed, his popularity in his own country was boundless, and his influence on the literature of other countries, particularly that of Spain, as powerful as it was mischievous. But good sense and good taste shortly resumed their sway, and Rousseau, if one may judge from the frequent quotations from Marini in his Heloise, would almost appear to be the last person of any literary distinction who was familiar with the once celebrated and now completely forgotten Adone.

Tassoni.

In comic poetry, however, the seventeenth century was more successful. To this period belongs the Secchia Rapita of Tassoni (1565–1635), the first specimen of that style which was afterwards carried to perfection in the Lutrin and the Rape of the Lock. The imitations of Tassoni need not be mentioned. Instead of improving on his model, they degraded and vulgarized it.

Excepting in the drama, which was distinguished by the great and strongly contrasted genius of Metastasio and Alfieri, the eighteenth century in Italy can boast of little in poetry. Some graceful fables by Pignotti, imitations of Pope by Parini, and of Gray and Young by Pindemonte, redeem it from the charge of utter barrenness, but cannot entitle it to the praise of originality. Nor, with the exception of Manzoni, has the nineteenth century produced any poem which can justly be said to have attained a European reputation. Giovanni Niccolini (born 1786), a professor in the Academy of Fine Arts at Florence, has composed several tragedies, one of which, Antonio Foscarini, founded upon a well-known episode in Venetian history, was received with much applause. Some of the lyrics of Silvio Pellico (born 1789) display considerable beauty and elegance of diction; and the improvisations of Tommaso Sgricci, which have been taken down in short-hand and published, display a wonderful faculty and command of language, though the sense, as might naturally be expected, is generally subordinate to the sound. The works of these writers, however, are not distinguished by that force and brilliancy which mark the earlier productions of Italian literature.

SPANISH POETRY.

Of all the languages formed from the ruins of the Latin, the Spanish approaches the nearest to the Italian. The spirit of the two literatures differs extremely; but so closely do the words resemble each other, that translations have been executed by Spaniards from the Italian, as in the case of Jauregui's translation of Tasso's Aminta, where even whole lines are found to correspond with the original. The language, as it now exists, is the dialect of Castille, polished and purified, the Catalonian or Limousin having long ceased to be the language of poetry.

Its orient character.

One feature peculiarly marks the whole of the Spanish poetry with a character unknown to that of the rest of Europe, viz., the strong traces of orientalism which it exhibits, a tendency to the pompous and the exaggerated, and a strange compound of strong passion, combining with a great wantonness and luxuriance of fancy. More or less this feature is to be traced through all the changes which its poetry has undergone; subdued, no doubt, and kept down by the good taste of such men as Garcilaso or Cervantes, but re-appearing in the *estilo culto* of Calderon, and reaching its height in the ludicrous extravagances of the Spanish Marini, Gongora. Considering, indeed, the intimate connection which subsisted between Spain and Arabia from the eighth down to the close of the fourteenth century, a connection which, though one of hostility in the field, appeared to have admitted of many of the ties of friendship and mutual respect, and the natural admiration which the brilliant poetry of Arabia was likely to exercise over the minds of a ruder people, the Asiatic character of the Spanish poetical genius appears exactly what, under such relations, might have been expected.

Chronicle of the Cid

The earliest monument of the Spanish poetry is the old Chronicle of the Cid, a cycle of romantic legends, founded upon the exploits and misfortunes of that Don Rodrigo Laynez, who, after exalting the glory of the Spanish arms under Ferdinand, King of Castille, and his son Don Sancho, was treated with such ingratitude by Alfonso VI., the son of the latter, that he fled to the Moorish court, where, from 1081 to 1085, he gained many brilliant victories over the Christian arms. Again recalled to the Spanish court by Alfonso, who began to feel his value, he was a second time disgraced, and banished about 1090. The Chronicle, which, both from internal and external evidence, appears to be as old as the twelfth century, relates to this second banishment; and though its language is rude, and its rhymes most imperfect, there is a captivating freshness in the scenes which it presents, in its vivacity of movement, and in the occasional traits of poetry which seem to escape almost involuntarily from the writer, that raise it considerably above the ordinary level of such chronicles.

Ballad poetry.

From the date of the poem of the Cid to the reign of John II. (1407–1454), the only monuments of Spanish poetry, at least the only specimens possessing the slightest interest, consist in that vast mass of popular or ballad poetry in which Spain is richer than any other country in Europe. Fortunately the process of collecting and preserving these relics of an adventurous and enthusiastic period, "ere polity, sedate and sage, had quenched the fires of feudal rage," was commenced at a very early period, the first collection having appeared in 1510, under the title of the *Cancionero General*. Not only in numbers, however, but in merit, the Spanish ballad poetry appears superior to that of any other nation of Europe. Everything, in fact, united to give to this species of poetry its freest development. A national character of strong sensibility, excitable yet constant; national pride, in the feeling that they had so long formed the advanced guard of Europe against the Moors, and were daily driving backward the tide of invasion; a life of adventure and gallantry; a strong passion for music and the dance; a delicious climate; a language rich in rhymes, and admitting a species of versification (the assonance) in which "Sponte sua carmen numeros veniebat ad aptos" were here found united. The result has been a collection of ballads of all kinds, warlike, amatory, Moorish (these last chiefly composed after the conquest of Granada by Ferdinand and Isabella in 1492), and satirical, marked by a degree of taste and poetical beauty of which very few of our English or Scottish ballads have to boast. The Moorish ballads have a peculiar charm, from the richness of the colouring with which they are invested, and their style, which has hit the happy medium between the boldness of some of the old historical ballads, and the over-refinement and affectation of those which were composed after the introduction of the Italian taste into Spanish poetry. The picturesque character of the Moorish life, the natural beauties and artificial magnificence of Granada, the quarrels of the rival families of the Zegris and the Abencerrages, the tournaments, feasts of canes, and other amusements of the luxurious court of Boabdil, afford in these ballads inexhaustible materials for descriptive poetry, a tendency which is hardly to be traced in the earlier ballads. "It is wonderful," says a very eminent Spanish critic, Quintana, "with what vigour and brevity they paint scenes, personages, and feelings. In one it is the Alcayde of Molina, who enters, rousing the Moors against the Christians, who are ravaging their fields; in another, the unfortunate Aliatar, borne back with the gloom of a funeral procession through the gate from which he had issued with such gaiety the day before; now it is a simple country maiden, who, having lost the ear-rings her lover had given her, weeps at the prospect of the reproaches which await her; and now a shepherd, who, solitary and forsaken, grows indignant at the sight of two turtles cooing in a neighbouring poplar, and drives them away with a stone." Besides the ballads descriptive of incidents, these collections contain many charming little songs and lyrical snatches, vague and undefined indeed, but often pleasing us even by this very vagueness, which merely suggests a hint to the mind, and leaves the rest to be filled up by the imagination. With few exceptions, the authors of these lyrics are unknown. A few are attributed to the great Don Juan Manuel (who died in 1362), but on doubtful evidence; the writers of the others have died and made no sign.

Though the Spaniards date the rise of their classic poetry from the reign of John II., it is certain this period contains little which has any interest for foreign readers. The pedantic and tedious Labyrinth (*El Laberinto*) of Juan de Mena (1412-1456), a cold and lifeless imitation of Dante's great poem, possesses nothing of a more classical nature than the older poetry, save its form. One poem only of this period,—viz., the noble stanzas or coplas written by Don Jorge Manrique on the death of his father, and a few graceful *redondillas* by the accomplished Marquis of Santillana, afford some relief from the pretension and pedantry which generally characterize this period of Spanish poetry.

Introduction of the Italian taste.
Boscan.

A great revolution, however, was about to be effected in Spanish taste by the introduction at once of the measures and of the spirit of the Italian poetry. The close relation into which Spain was brought with Italy during the reign of Charles V. had led to a general knowledge of the treasures of Italian poetry; while many changes in the political constitution and habits of the Spaniards themselves concurred to weaken their attachment to their old and natural romantic poetry, and disposed them to adopt the more regular and polished strains of their Italian neighbours. This change was introduced by Don Juan Boscan (from about 1500 to 1544), who, though he had at first composed and published a volume of poems in the old Spanish manner, had been led, by his acquaintance with the Venetian ambassador Navagero, to the study of the Italian classics, and in consequence formed the design, in conjunction with his friend Garcilaso de la Vega (1500–1536), of introducing to his countrymen the refinements of the Italian versification, and the superior polish of the style of the Petrarchists. But with all Boscan's careful study of the Italian poets, which is evident from the perpetual imitations which his poetry contains of Petrarch, Bembo, and Sannazzaro, he never could acquire their elegance of taste, nor divest himself of the national tendency to orientalism. Something of the old leaven of impetuosity and hyperbole attaches to his poetry, producing a feeling of incoherence between the matter itself and the medium through which the ideas are conveyed.

Garcilaso.

But what Boscan attempted and imperfectly performed, Garcilaso accomplished with complete success. He was equally distinguished in the field of warfare and of literature. "One hand the sword employed, and one the pen;" and he fell at last, crowned at once with the laurels of poetry and war. In Garcilaso the Italian poets found a rival, if not a superior; for while he adopted their best points, he avoided in a great measure that subtlety of taste which had grown out of the study of the later Platonists, and introduced a metaphysical and reasoning style into those subjects where it was the most out of place. Garcilaso has written little, but that little (at least his Eclogues, for his Sonnets are not of equal merit) is of the highest class; for he has contrived so finely to temper the subtlety of the Italian poets by the more natural warmth of the Spanish, and to clothe his sentiments in words at once so simple and so classically pure, that the result is something superior to anything that is to be found in his models. In all of them, no doubt, the classic reader will recognise at every turn resemblances to the Latin poets; but these imitations are introduced with so much taste, and fitted with such art into a Spanish framework, that the knowledge that they are imitations rather increases than diminishes our sense of the talent of the poet.

Mendoza.

A third personage was associated with Boscan and Garcilaso in this poetical triumvirate, the famous "tyrant of Sienna," the accomplished warrior, statesman, historian, novelist, and poet, Diego de Mendoza (1500–1575). Mendoza's Epistles, however, betray more rudeness of manner than even the verses of Boscan; and indeed the chief feature of interest which they possess is, the singular spectacle they present of a stern and hard-hearted warrior of the school of the Duke of Alva breathing out to his friends Boscan and Zuniga the most fervent aspirations after the domestic happiness of a rural life, or longings for the enjoyment of a philosophical solitude. This feature, indeed, more or less marks the whole poetry of the period. Whilst the Spanish warriors were distinguished all over Europe for their ferocity, presenting, as Sismondi says, "to the enemy a front of iron, and to the unfortunate an iron heart," we find all their poetry marked with a dreamy, tender, and melancholy spirit. In Mendoza, Garcilaso, and Montemayor, all of whom were soldiers, and conversant with scenes little calculated to soften the affections, we observe this union of practical ferocity with theoretical innocence; nay, even the terrible Duke of Alva appears to have been inspired by the same tastes, and appears in the poetry of the time, not as the ferocious governor of the Low Countries and the organ of the Inquisition, but as the discerning critic, the lover and the patron of literature.

Montemayor.

This tendency to themes of an Arcadian cast gave rise to the Pastorals of Montemayor (1520–1561) and his successors. The Diana of Montemayor, a pastoral romance, interspersed with ballads and canzoni in the style of Sannazzaro's Arcadia, was once amongst the most popular productions of Europe. Its influence may be traced, not only in the host of Spanish pastorals which succeeded it, but in the literature of other countries, in the Astrea of D'Urfé, and in the Arcadia of our own Sir Philip Sydney. Cervantes bestows upon it a sort of qualified praise in his review of Don Quixote's library, but is disposed to give the preference to the continuation by Gil Polo over the original. Montemayor labours, in fact, under the fault of all his countrymen of the time: he cannot compress; he pours out a stream of musical language, "which runs, and, as it runs, for ever would run on;" but he gives us few ideas that are at once natural and new, and none that stir the heart or strongly awaken the imagination.

Herrera.

The works of Herrera, another poet of this period (1500–1578), on whom the Spaniards have, with questionable propriety, bestowed the title of "the Divine," are in a totally different strain. His themes are religious and warlike, such as the triumph of the Christian arms at Lepanto, or the fatal defeat of Sebastian in his expedition to Africa. Of all the Spanish poets, Herrera, whose mind was deeply imbued with the beauties of the sacred writings, possesses the loftiest style of expression; but the majesty of his diction is often obscured by strange and new creations or combinations of words, while his elevation not unfrequently explodes in palpable bombast. There is a strong resemblance between Herrera and the Italian Chiabrera, both in their beauties and their faults.

Luis de Leon.

The greatest of the Spanish lyrical writers is Luis Ponce de Leon (1527–1591). "More earnest and enthusiastic than Boscan; tender as Garcilaso, but with a soul whose tenderness was engrossed by heavenly, not earthly love; pure and high-hearted, with the nobility of genius stamped upon his brow, but with religious resignation calming his heart, he is different from his predecessors, but more complete; a man Spain only could produce, for in Spain only had religion such sovereign sway as wholly to reduce the rebel inclinations of man, and, by substituting supernal for terrestrial love, not diminish the fulness and tenderness of passion, but only give it another object."[1] The most remarkable feature of Luis de Leon's poetry is the union of a mystical and religious enthusiasm with the most perfect clearness and transparency of expression. Never was a high and soaring imagination more perfectly under the control of a cool judgment and a critical taste. Whilst a religious Platonism forms the *fond* of his odes, the style exhibits all the terseness, precision, and finish of that of Horace, of whom, notwithstanding the great differences in their poetical character, he continually reminds us, by the sententious air of his odes, and that serene moral wisdom which drops from him in common with the Epicurean poet, whatever subject he touches on. But the odes of the Spanish poet have a moral grandeur far exceeding those of Horace. The spirit of present enjoyment, or indifference to futurity, which not unnaturally pervades the latter, was revolting to the warm sympathies and devout belief of Luis de Leon. Accordingly, the ideas and images which, to the Epicurean poet, only afford inducements to devote the hours to pleasure, such as the shortness of life, the fading of flowers, or the instability of fortune, the Spanish moralist holds out as inducements to the cultivation of those higher faculties which raise the soul above this world of mutability and misfortune, and prepare it for that purer abode which he regarded as its appointed home.

Drama.

The close of the reign of Charles V. is adorned by the great name of Cervantes (1547–1616), more distinguished, however, as a prose writer than as a poet; and by the rise of the dramatic literature of Spain. For a general account of the peculiarly national and remarkable character of the Spanish theatre, which, while it is connected with our own by so many common features, has yet some striking points of distinction which render its study peculiarly interesting to the admirers of our older British theatre, we refer to the article DRAMA. Cervantes, we must admit, appears to mark its *childhood;* for the plots of his dramas are loose, disjointed, and scarcely deserving of the name, though the gloomy grandeur of the Numantia gives it a painful fascination, like the scenes in the tower of Hunger in the Inferno. Lope is identified with its boyhood; Calderon, with its maturity and perfection; Moreto, Roxas, De Solis, Mira da Mescua, Da Hoz, and others, who wrote during the reign of Philip IV., with its decline. Invention, high poetry in parts, the power of exciting and maintaining curiosity and suspense, must be accorded to the Spanish theatre. Against these must be set religious bigotry and mysticism, often painfully predominant in the plays of Calderon, particularly in those autos which the German critics have especially selected as the themes of their admiration; the affected and redundant style into which most of their poets were led by the facility of their versification, combined with the habit of working for the stage; and the practice which, upon the Spanish stage, is almost universal, of painting manners and general types of character, rather than discriminating its shades, or giving individuality to the personages represented.

We may here notice, in connection with Spanish literature, the solitary great name of which the kindred literature of Portugal has to boast, Luis de Camoëns (1524–1578), who conferred upon his countrymen that which Spain has in vain essayed to produce; for the Araucana of Ercilla certainly does not deserve the title of an epic poem. Viewed in this light, too, it must be admitted that even the Lusiadas of Camoëns is most objectionable: the action flags miserably; the mythology is ludicrous; the morality of some portions of the poem, as, for instance, the scenes on the island which Venus prepares for the refreshment of the returning Portuguese, is more than questionable; but, with all these, the work is inspired and supported by the true spirit of poetry; and its continued popularity and reputation prove how little the real charm or success of an epic depends on the mere plan or machinery of a poem. That which will always render Camoëns delightful is, the tenderness of heart which overflows in such episodes as that of Ignez de Castro; and the pride and zealous endeavour with which he labours to embody in immortal verse the spirit of those days in the annals of Portugal when learning and commerce, warlike enterprise and success, went hand in hand; when De Gama braved the terrors of the Cape, and Alvarez and Albuquerque first launched their galleys into the Atlantic.

Gongor and Qu vedo.

From the seventeenth century to the present time, the literature of Spain has been one of decline. Three names only amongst the many whose works are found quoted in Anthologies and *Parnasos* deserve notice; those of Gongora (1561–1627), Quevedo (1580–1645), and Villegas (1595–1669). The real talents and rich imagination possessed by Gongora make us lament that, like Marini (from whom, indeed, he borrowed his manner), he applied them only to corrupt and pervert the public taste. Some of his little anacreontic verses, songs, and letrillas, written at an earlier period of his life, are models of natural grace and felicity of expression, contrasting most painfully with the ridiculous jargon of language and *galimatias* of sentiment which he employed in his later days. The same evil tendency is visible in Quevedo. We have great invention, much acuteness and comic humour, but a lamentable deficiency of feeling and taste. His works have been most justly compared by Bouterwek to a massive ornament of jewellery, in which the setting of some parts is exquisitely skilful, of others extremely rude, and in which the number of false stones and of valuable gems is nearly equal.

---

[1] *Literary and Scientific Men of Italy*, vol. iii., p. 70.

Villegas. A purer taste occasionally appears in Villegas, the Anacreon of Spain, though he, too, seems to labour under the mania of the day, and now and then to run into extravagances worthy of the very wildest of the Cultoristos. After Villegas there appeared no Spanish poet of any originality; for the verses and the pastoral comedy of Melendez Valdez, founded on the episode of the marriage of Camacho in Don Quixote, do not rise above mediocrity; the fables of Yriarte have merely the merit of brevity and neatness of expression; and the comedies of the younger Moratin, the last dramatic works which have attracted any attention, are merely ingenious imitations of Molière. At the present moment Spanish poetry would seem to be absolutely *effete;* nor does there appear much reason to anticipate its speedy revival. The few compositions of Martinez de la Rosa, and of Angel de Saavedra, are not of sufficient merit or importance to rescue the recent literature of their country from this reproach.

FRENCH POETRY.

The present language of France has sprung from that northern dialect which was spoken in Normandy, and known by the name of the Walloon. The earliest compositions in that dialect were romances, founded on some fabulous history, such as Brut of England, which appeared about 1155. **Romances.** To these succeeded the romances of chivalry, from about 1130 to 1190, of which, unless the Portuguese romance of Lobeira, Palmerin of England, be supposed to have appeared before this time, it would seem the Norman-French are fairly entitled to claim the invention. Taking them as a whole, there is no disputing that much fancy and ingenuity are expended upon these now-forgotten performances, though the style is invariably flat and lumbering. They are sustained merely by the high spirit which they breathe, and the happy incidents which the chronicler occasionally introduces.

Allegorical romance. The taste for the allegorical romance was of a date somewhat posterior. Of these singular compositions, the most remarkable is the once celebrated *Roman de la Rose*, begun by William de Lorris, and concluded by Jean de Meun, a poem which was received with boundless admiration, and which continued for a century strongly to influence the literature of Europe. It was at once a romantic and an allegorical poem; a new edition of the art of love, adapted to the moral and metaphysical creed of the middle ages; of dreary length, and yet enlivened here and there by allegorical portraits of imaginary personages, drawn with considerable vivacity and spirit, and by those strokes of satire, or lessons of practical philosophy, which, together with the art of narration, very early began to characterize the literature of France. The conclusion, by Jean de Meun, is inferior to the commencement; it is deformed by a ribaldry and coarseness which justifies the term "niedrige polissonerie," or low blackguardism, applied to it by Bouterwek.

The Fabliaux. But by far the most striking and characteristic part of the early French literature consists in that vast collection of short tales entitled Fabliaux, which were almost exclusively the production of the French provinces lying to the north of the Loire, and which are well deserving of attention, whether their own merits and originality be regarded, or their general influence on fiction. The period of their appearance extends from the last half of the twelfth through the whole of the thirteenth and part of the fourteenth century, but the greater number are supposed to have been written during the reign of St Louis (1226 to 1270). The compositions of these ministrels differ extremely in character from those of their Provençal brethren of the south of France. The poets of Provence were generally knights and nobles; their themes love or war, or mystical allegoric dreams; and, with much monotony, their poetry certainly presents an elevated and imposing exterior. The Trouvères were generally men of an inferior grade, sprung from the lower ranks of life; in fact, literally wandering minstrels. Yet the position they occupied in society was particularly favourable to the promotion of those habits of satirical observation and comic description which constitute the chief attraction of the Fabliaux. Men in general of acute and vigorous minds, though destitute of learning and delicacy, and too often of principle; welcome guests in all society from their powers of amusing, yet respected in none; experiencing every extreme of life, and making themselves at home in all; sometimes helping to dispel the ennui of baronial castles, at others courting the society of the humblest vassals, they rambled over the world, harp in hand, as it were, picking up everywhere the materials of their art, and thus painting, with a truth and freshness otherwise unattainable, the full-length portrait of French manners during the thirteenth and fourteenth centuries. These light and joyous compositions turn chiefly on subjects of a familiar nature, and consist of stories of knavery and intrigue, and occasionally of those Asiatic legends with which the Crusades had by this time rendered Europe familiar. Except, therefore, in invention of ingenious incidents and comic imbroglios, and in a certain tinge of humour and vivacity which breathes of the sunny skies and vine-covered hills of France, they have little pretensions to poetry. And yet this opinion must be taken with exceptions, for they have occasionally shown that they could excel in themes of a higher kind; and the beautiful and well-known fabliau of Aucassin and Nicollette, by its tender and natural spirit, combined with the deep interest of its situations, throws into the shade the greater part of the more ambitious and elaborate chivalrous romances. We perceive in it all the romantic spirit and deep feeling of the old Spanish ballads, heightened by the graceful naïveté peculiar to the early French poetry.

The period from the commencement of the fifteenth to the sixteenth century is regarded by the French as the transition period of their poetry from infancy to maturity; and the three leading names of the period are Marot, Ronsard, and Malherbe.

Marot. Clement Marot (born 1495, died 1544) is the creator of that school of naïve poetry which was afterwards carried to its perfection by La Fontaine and Voltaire. With a playful, unambitious grace, he gives a happy turn to every subject, and delights to put the world in good humour with itself. It is justly observed by a French critic, Nisard, that the naïveté of Marot differs from that of any previous poet. In the older strains of the Trouvères and their successors what we call naïveté often arises merely from the imperfection of the language, and not from any peculiarity in their turn of mind. But Marot wears this air of unconsciousness even in giving expression to ideas the most subtle and recherché; his naïveté seems independent of the language, independent almost of the ideas; it is an emanation of the peculiar genius and idiosyncracy of the man.

Ronsard. It is amusing to contrast the fame of Ronsard during his life (1524–1585) with his reputation at the present moment. His own age elevated him to honours almost divine: in the present how many are acquainted even with a single page of his poems? He was considered the presiding luminary of that constellation of genius which arrogated to itself the title of the French Pleiad, whose great object it was to transplant into French the form and the manner of the lyrics of antiquity; but who succeeded only, as Boileau says, in making a jumble of everything (*brouiller tout*), a patchwork, in short, of Greek and Latin ideas with Italian subtlety of thought and French naïveté of expression.

Malherbe. "Enfin Malherbe vint," says Boileau (1558–1628), like Ronsard a classicist, but endeavouring, and not without success, to seize rather the spirit of the ancients than their forms. Of the higher inspiration of the ode he had little; his march is stately enough, but it is measured and slow; he has little or no enthusiasm, but in all that regarded the judicious treatment of a subject, or the minutiæ of language or versification, he was well fitted to be the legislator of that new and more sober school of composition which superseded in France the extravagances of Ronsard and his satellites. The three pieces of Malherbe which appear to indicate the highest talent, approaching indeed to genius, are the Ode to Henri IV. on the taking of Sedan, the Ode to the Queen-Mother, and the beautiful verses addressed to the Councillor Duperier on the sudden death of his daughter.

Age of Louis XIV. We now arrive at the period which is, or rather was, considered by the French as the golden age of their poetical literature, the long reign of Louis XIV. Everything at this time concurred to impress on poetry that stamp of stateliness, polish, and courtier-like adoration of monarchy which then pervaded French society, and which exerted so powerful an influence on the general tastes of Europe. The French monarchy had now been consolidated by the firm hand of Richelieu, who, whilst he unrelentingly pursued his design of lowering the aristocracy and exalting the throne, was not insensible to the claims or the importance of literature, and had been the first to give it the support which a corporate character appeared likely to afford, by the formation of the celebrated Academy. The troubles of the Fronde were over. The heats and animosities of rival religions had been appeased by the edict of Nantes. The personal character of Louis was well suited to effect his main object, which was to render his court a model for the imitation of the world. Of limited abilities, without talent either for warfare or diplomacy, he possessed tact enough to perceive at once his deficiencies and his advantages; and, endowed with many of the most attractive outward graces and accomplishments of a king, he played the part of a dignified monarch with much discretion and ability. Thus wielding, without opposition, the energies of a powerful kingdom, and collecting around him at his court all that France contained of intellectual ability, a tone of courtly polish and extreme refinement was imparted to society which soon impressed its traces upon literature, partly for good, and partly for evil. The influence exercised by French manners and French literature upon other countries became paramount and unprecedented, superseding the most inveterate usages, overturning the strongest national prejudices, and establishing a despotism more universal than had been known in literature since the downfall of Greece and Rome.

The most imposing shape in which poetry appears during this supposed Augustan period of French literature is in that of the drama, which, commencing with the rude plays of Jodelle (who died in 1560), reached its perfection during the close of the reign of Louis XIII. and the reign of Louis XIV., in the tragedies of Corneille and Racine, and the exquisite comedies of Molière. (For a full account of the French stage, we refer to the article Drama.)

It cannot be said that, in any other department of poetry except that of the drama, the age of Louis XIV. was pre-eminently distinguished; for the artificial and hollow refinement of the time seemed unfavourable to that vigorous and natural feeling which should speak in poetry, with a corresponding strength and originality of expression. Yet two names impress themselves, by their strongly discriminated traits, upon the memory,—La Fontaine (1621–1695) as the reviver of the old naïve style of Marot, though with a degree of polish and grace of which Marot had no conception; and Boileau, as the representative of that school of terse morality, sound sense, and wit, mingled with and heightened by fancy, of which Pope is the best example in English poetry.

La Fontaine. With all the levity and licentiousness which deform the Contes, there is no denying to La Fontaine many of the best qualities of the poet; knowledge of the world, which yet does not impair his bonhommie and kindness of heart; a humour playful, gentle, continuous, never pushed to excess, combined with tenderness, with a disposition to reverie and pensiveness; a strong sensibility to the beauties of the country, of which his descriptions, though short, are always striking, and marked by that just selection of points and clear local portraiture which we find in Crabbe, and which show that he made his studies for them on the spot; the whole heightened and set off by a style apparently simplicity itself, but which must have been, as we know it was, the result of the most laborious polishing and elimination: all these give an extreme charm to the Contes, and perhaps still more to the Fables, of La Fontaine; for the Contes, though their licentious gaiety has made them more generally known, display to less advantage the peculiar qualities of La Fontaine's genius.

Boileau. Boileau, again (1636–1711), pleases and must always please, although by qualities the most opposite to those of La Fontaine; namely, by awakening a calm emotion of intellectual satisfaction, rather than by any excitement of the imagination or the feelings. As Racine represents the tender and voluptuous side of French manners and character during the age of Louis XIV.; as La Fontaine embodies in his tales and fables its easy tone of moral indifference and *malice*, masking itself under the disguise of simplicity; so in Boileau we find, arrayed in a dignified and philosophical dress, its better points, its good sense and sagacity, its lively perception of the eccentric and ridiculous, its love of external decency, order, and propriety, both in morality and in literature.

In his Lutrin he even displays a considerable degree of invention, though chiefly of a comic kind; for, though not destitute of a sense and feeling of high poetry, he was essentially deficient in any actual power of dealing with such themes; and, with that tact and judgment which distinguished him, he has rarely, save in his most unfortunate Ode on the taking of Namur, which has been so justly but so unmercifully parodied by Prior, ventured within this province of poetry. Within his proper field of moral censorship, or of the mock heroic, arrayed in all the graces of elegant diction and classic allusion,—or the poetical abridgment, in the most condensed and pointed form, of the approved critical canons of the time,—he is assuredly without a rival in French poetry, and, with the exception of Pope, in European literature.

Eighteent century. Rousseau. The literature of the eighteenth century in France is more distinguished by its prose than its poetry. Prior to Voltaire, at least, in whom great and versatile powers of mind, approaching if not attaining to high genius, must be admitted, it added nothing of substantial value to the contributions of the age of Louis XIV. At one time, indeed, the odes of J. B. Rousseau (1669–1741) were extolled to the skies, as models of lyric poetry; and Voltaire certainly speaks of them in terms of extravagant praise. To any one now perusing them, with the recollection of the great models of antiquity before him, or even testing them by the simpler process of his own feelings, they will assuredly appear totally deficient in genuine inspiration. The enthusiasm is imitative and factitious; the imitation dexterous, no doubt, but yet palpable to every one who possesses any real poetical sensibility; the thought is often propped up by the words, not the words elevated and quickened unconsciously by the vital grandeur of the thought. What true lyric enthusiasm, indeed, could reside in a mind which busied itself alternately in the composition of rapturous religious odes and epigrams of disgusting obscenity?

Chaulieu and Gresset.

Much more of real poetry, because accompanied by nature and simplicity, is to be found in Chaulieu's pastoral lyrics; in some of the little romances of Moncrif, such as Alexis and Alix, which abounds with lines that by their truth and simplicity of expression have become proverbial; or in Gresset's pleasing stanzas on the golden age, or even in his lively tale of Vert-Vert.

Voltaire.

The reputation of Voltaire (1694–1778) at the present day rests more upon his witty and amusing prose than upon his poetry. The didactic tendency which was the spirit of the age, that attempt to make all the creations of poetry subservient to inculcating certain philosophical opinions, appears in all the poetry of Voltaire; it speaks even in Mahomet and in Zane, as much as in his graceful occasional verses, his tales in the manner of La Fontaine, or his epistles. "Les François n'ont pas la tête Epique," was his own expression; and the Henriade certainly went far to prove the fact. It is the mere *simulacrum* of an epic,—hard, laboured, soulless. It is most unfortunate for Voltaire that the poem in which his versatile abilities have been displayed to the greatest advantage is one which its indecencies and impieties have in a great measure banished beyond the pale of literature.

About 1770 may be noticed the rise of the descriptive school of poetry, in the poems of St Lambert and Delille; an importation in all probability from England, where a similar taste had been introduced by the success of the Seasons of Thomson. From 1730 to the commencement of the present century numerous attempts were also made to confer on France something that should merit the title of an epic poem; but without the slightest success.

During the despotism of Napoleon poetry appeared to be almost silent. With the restoration of the Bourbons appears the rise of that romantic school, the growth of the fermentation of the revolution, and of that removal of the old landmarks both in polity and opinions which it caused; a school which, both in theory and practice, repudiates the principles of the old French classicists, and has certainly effected a complete revolution in the literary tastes of the time.

Hugo, Delavigne.

With regard to the quality of the poetry so produced there may be, and has been, much diversity of opinion. Those who admire the formal manner and stilted versification of the old French writers will probably not be disposed to allow much merit to the vehement odes and fiery utterances of Victor Hugo and Casimir Delavigne; nevertheless their innate vigour has gained for them not only the applause of their countrymen, but the favourable opinion of some competent critics on this side of the Channel. It must be allowed that the writings of Victor Hugo are very unequal in their merit. Sometimes he is extravagant even to the verge of bombast; at other times bizarre; but occasionally he rises with his subject, and exhibits a rare mastery of language and much poetical imagination. Few short poems in any modern European tongue can be advantageously compared with his Chant de Fête de Néron. His dramas are of a mixed character. Perhaps the best of these are his Marion Delorme and his Le Roi s'amuse; the first fulfilling nearly all the conditions of a high tragedy; the second resembling in manner and power some of the best compositions of the elder English dramatists. The genius of Delavigne derived its inspiration from patriotic sentiments, and has found vent in many noble lyrics. Of these, Parthénope and Le Chien du Louvre may be cited as notable examples. Alfred de Vigny, a poet somewhat less known to English readers than the others whose names we have just cited, has gained much popularity in Paris; and not undeservedly, for in his poem entitled La Frégate la Sérieuse he has exhibited a pathetic earnestness rarely found among the writers of his school. Auguste Barbier also deserves mention on account of his energy and descriptive power. But the names which are most conspicuous in modern French poetry, and which will hereafter be most intimately associated with the literature of the first half of the nineteenth century, are those of Lamartine and Beranger.

Lamartine.

It has been the fortune or destiny of Lamartine to occupy a conspicuous position in two characters usually thought to be irreconcilable,—first, as a poet, and secondly, as a politician. His disastrous failure in the latter capacity leads us to regret that he had not devoted himself exclusively to the cultivation of his literary talent, which was, beyond all doubt, of a rare and distinguished order. In his poetry there is a stateliness, a sustained gravity, at times almost reaching to the sublime, which we look for in vain not only in the writings of his contemporaries, but of his predecessors. Very melodious in his expression, he has succeeded in producing harmonies of which the French language seemed scarcely capable; thus furnishing a new and convincing proof that it is possible, by care and dexterity, to render flexible the most difficult speech, and to make it subservient to the highest purposes of art. The French language, admirably adapted for conversational purposes, for brilliant repartee, witty turns, and all the lighter graces of diction, was supposed to be unfitted for oratorical use, until Bossuet and Massillon, by their magnificent discourses, upon which the utmost elaboration was bestowed, dispelled that illusion. In like manner, Lamartine has shown us that it is possible so to wield that language as in poetry to reach the sublime. He does not, however, possess the power, certainly not the imagination, to sustain him through a Miltonic flight. Much more aptly may he be compared with Wordsworth, to whom, indeed, in quality and tone of mind he exhibits a marked resemblance. The solidity, magniloquence, and reflective tendencies of the English poet, are conspicuous in the writing of his French brother; but so also are his occasional tediousness, egotism, and pomposity. Lamartine never has divorced his subject from himself; possibly, from his mental conformation, it was impossible for him to have done so. Hence, after a time, we rather experience a feeling of fatigue in the perusal of his poetry, finding the same cast of thought monotonously repeated. We admire the man; we appreciate his sentiments; but we cannot help wishing that he would sometimes forget himself so far as to free us from the consciousness of his perpetual presence; just as, when we are contemplating a beautiful diorama, we feel annoyed at the platitudes of the showman. But, notwithstanding this, Lamartine has won, and will deservedly maintain, a very high rank in the poetical literature of his country.

Beranger.

A greater however is behind. We shall close this short notice of French poetry with the name of one who, though partaking of all the modern influences of his time, was yet within his own department, that of song, a genuine classic. In this department of the lyric France has always been distinguished. In that country not only has it constituted, as elsewhere, the amusement of the lower classes, but it has long attained the dignity of a powerful political agent; its monarchy was justly described by Champfort as a despotism tempered by songs. Of all the modes in which poetry can be made subservient to purposes like these, song is the most effective, universal, and immediate in its operation. It speaks not to a particular class, but to all; its brevity fixes it in the memory; the creature of the moment, it avails itself of every allusion, every passion, every prejudice of the day; while its outward form appears so trivial and harmless that even despotic governments are deterred, by the fear of ridicule, from attempting to interfere with it. Beranger, while he has selected the simplest, the most universal feelings, the most familiar sentiments and images, provided they are true, unforced, and natural, yet, by the tact and skill which he has employed in their treatment, and the felicity of their expression, has invested them with quite an original character. The oftener a thought has occurred to others, so much the better with him; for it is an evidence of its truth, and of its power of affecting the heart. What remained for him, and what he has performed, was to impart to this thought, so familiar to all, though perhaps vaguely and indefinitely, form, colour, expression; so that when presented by him to our notice, it is felt at once to be an old acquaintance, and yet awakens all the curiosity and interest with which we regard a new one. His originality, in short, lies entirely in his application of the idea, and the point and compactness with which the image is brought out by his hands. Few poets in this department have ever gained greater success. What Burns was to Scotland, Beranger is to France. He seized upon the popular feeling, treated it as it ought to be treated, by giving it that garb and expression which genius alone can bestow. Strong in his Napoleonic tendencies and faith, he kept alive among the people of France the grand memories of the empire; and to his ballads and soul-stirring ditties, more than to any other cause, may be attributed the re-establishment of the Corsican dynasty. No other poet since the beginning of the world has exercised such a power over the destiny of a nation.

GERMAN POETRY.

We have noticed the early development of German heroic song in the Nibelungen and the Heldenbuch; and the introduction of the Provençal taste under the Suabian emperors in the poetry of the Minnesingers. In all its leading features the poetry of this period (1138 to 1346) corresponds with that of the French Troubadours, with this unfavourable distinction, that the poetry of the Minnesingers (love-singers) is much more exclusively devoted to amatory themes than that of the Provençals, which blended with these, warlike and patriotic or satirical effusions. Hence their monotony of effect, when we peruse any of these collections at once, is undeniable. Schiller has accordingly, in a passage of unusual severity, denounced their poverty of ideas, and says that if the sparrows were to compose an "almanack of love and friendship," it would probably bear a close resemblance to these cloying strains of the Minnesingers. But against this sarcastic remark must be placed the observations of Frederick Schlegel: "The impression of uniformity arises from our seeing these poems bound together into large collections, a fate which was probably neither the design nor the hope of those who composed them. But, in truth, not only love-songs, but all lyrical poems, if they are really true to nature, and aim at nothing more than the expression of individual feelings, must necessarily be confined within a very narrow range both of thought and sentiment. The truth is, that great variety in lyrical poetry is never to be found, except in those ages of imitation when men are fond of treating of all manner of subjects in all manner of forms. Then, indeed, we often find the tone and taste of twenty different ages and nations brought together within the same collection, and observe that the popularity of the poet is increased exactly in proportion as he descends from his proper dignity, when simplicity is sacrificed to conceits and epigrams, and the ode sinks into an occasional copy of verses."

The opening of German poetry, then, had been on the whole brilliant and promising; but the confusion, insecurity, and violence which followed the death of Frederick II. in 1250, seemed fatal to the progress of improvement. After Rudolph of Hapsburg, we perceive in its poetry a visible decline. The Minnesingers were succeeded by the Mastersingers, personages who seemed to think poetry was to be acquired like any other trade, and to be supported and kept alive by guilds and corporations. It is difficult, perhaps, to point out at what precise period the former school of poetry ends and the latter begins; they melt into each other like the colours of the rainbow. But the character of the two schools, taken in the mass, is very different; for, in place of the tender, thrilling, amatory spirit of the Minnesingers, the great object of the poetical craftsmen who succeeded them was to give a didactic and philosophical air to their compositions, and to substitute for fancy and feeling commonplace truisms and moral aphorisms. One work only of this period deserves notice, not indeed on account of its high poetry, but of its shrewdness, its effective satire, and its invention, the comic epic, as it may be called, of Reynard the Fox, the groundwork of which no doubt existed before in other countries; but the novelty of the treatment of the subject by the German or Frisiac writer, and the great superiority of its execution, entitle it to the character of an original work.

From the close of the fifteenth to the middle of the eighteenth century, a dreary blank intervenes in the poetical annals of Germany. Bouterwek has indeed devoted more than a volume of his valuable work to this period; but, whatever interest the minute detail of second-rate names may have for Germans, there is certainly little or nothing calculated to awaken the least interest in the foreign reader. The effects of the Thirty Years' War were felt in Germany, paralysing science, general culture, and the spirit of poetry, up to the time of the peace of Westphalia. Opitz and Flemming are the only poets who rise above the dead-level of the mediocrity of the time. Opitz was a great importer from other countries, many of his poetical consignments being derived from Holland. Yet, though not a man of original mind, his strong good sense, a sincere honesty of mind, and a patriotic inspiration, render his poetry even now readable; though probably few are disposed to concur with F. Schlegel in preferring his style to that of Klopstock. Flemming is an inferior poet to Opitz, and yet perhaps his poetry is more interesting, precisely because it is more personal; because it lets us into the secret of his feelings, his friendships, and attachments. Hoffmanswaldau and Lohenstein enjoy the evil distinction of having corrupted, by the most false and fantastic taste, that poetry which was already but too destitute of any great pretensions. We ought, however, to make an exception in favour of Paul Gerhard (1606–1676), whose religious poetry is of a very high order of merit. Deeply pious and enthusiastic, the spirit of adoration breathes throughout his hymns, which are still most popular, and are justly regarded as masterpieces of their kind. The period from 1648 to nearly 1750 is characterized by Schlegel as the age of barbarism,—a chaotic interregnum in the history of German literature. Poetry existed in no other shape than that of feeble imitations of the French, profuse of mythology, penurious of feeling, destitute of nationality. "Apollo," says Menzel, "sat on the German Parnassus in a full-bottomed peruke, and, with fiddle in hand, led the concert of the well-powdered Muses."

Klopstock.

When at last the German Muse began to arouse herself from her torpor, and to "awake a louder and a loftier strain," she received no countenance from royal patronage. The great Frederick despised and disliked the literature of his countrymen, and seemed to think there was no hope for poetry save in a slavish adherence to the spirit and the rules of the French. If Klopstock (1708–1803) had done nothing more than awaken the feeling of nationality by his poetry, and teach his countrymen that, in the free and independent cultivation of their own genius, and the selection of their own themes, lay their only chance of redeeming Germany from the state of torpor into which its poetry had fallen, he would have conferred an inestimable service on its literature. With the Messiah, Schlegel thinks the modern poetry of Germany may be said to have begun, so great have been the benefits which it has conferred in regard to style and expression, as well as in the spirit of nationality and religious feeling which it imparted to the poetry by which it was succeeded. The plan, indeed, labours under great and insuperable defects. The mind of Klopstock was but ill suited to the epic; it was eminently lyrical and elegiac. Nor can it be denied that there is a degree of rhetorical pomp and long-windedness about his style, which becomes frequently oppressive, and communicates an air of pedantry to his poem. Still, Klopstock has exercised an important and beneficent influence upon German literature; he taught his country its own strength, and freed it at once and for ever from the leading strings of foreign authority.

Wieland.

Wieland (1733–1813) is more French in character than Klopstock, or rather he blends the luxurious and somewhat licentious spirit of the Italian romantic poets with that tone of gay and heartless philosophy which the example of Voltaire had introduced into French literature; and yet, withal, he is no mere imitator, but possesses a decided individuality in his later and better works, and even a truly German spirit. The tendency towards the imitation of the French appears, however, chiefly in the earlier productions of his romantic muse, such as the Idris and Zenide, the New Amadis, and others, in which he has assailed with such persevering satire the Platonism of love. As he advanced in life, he began to entertain better views; he grew dissatisfied with that epicurism which he had inculcated as the basis of conduct, and that licentious gaiety which he had made the mainspring of his poetry; and in his Oberon he endeavoured to make amends for the levity with which he had treated the better feelings of the heart, by those charming pictures of conjugal love, true constancy, and chivalrous heroism, which, combined with the beauty of the descriptions, and the pure and simple flow of the style, have rendered the Oberon the only successful effort in later times to revive the tones of that Italian harp which has slumbered since the days of Ariosto.

Gessner.

Gessner (1783-1788) belongs to this period. His Eclogues at one time enjoyed great popularity; and he has certainly in some of them, such as the First Navigation, displayed fancy and invention. But he deals in a species of poetry too remote from actual life; and there is a sort of sheepish modesty about his shepherds, and French coquetry about his nymphs and shepherdesses, which communicate something of a ludicrous character to his Arcadia.

Lossing.

The fame of Lessing (1721-1781) must rest more upon his vigorous, transparent, logical, and delightful prose style, than upon his poetry. His dramas, with the exception of Nathan the Wise, are written in prose; and the style of Nathan scarcely rises above the conversational pitch, though its Brahmin-like simplicity of tone, and the air of mild and tolerant wisdom which pervades it, leave a pleasing impression on the memory.

Schiller, Goethe.

The two greatest names in German literature succeed,—namely, Schiller (1759-1805) and Goethe (1749-1832). Of their dramas we have spoken elsewhere. Schiller, however, though greatest as a dramatist, is entitled to nearly equal eminence as a lyric poet. His odes, his short poems, mingling so much philosophy with so much feeling; his charming ballads, pitched on every key, from the simplicity of the Toggenburg and the Fridolin to the rude force of the Diver; the fine chivalrous and devotional tone of the fight with the dragon, and the classic finish of the complaint of Ceres or the cranes of Ibycus; would alone have been sufficient to place him second only to Goethe, had he never written William Tell, or the Maid of Orleans, or Wallenstein. In one particular he must rank far higher than Goethe: in the elevated aim which he always had in view; the attainment of noble ends by noble means; the rendering poetry what it always ought to be, not a mere specimen of plastic ingenuity, but something by which the soul feels itself refined and the heart made better. His enthusiasm—impetuous, and yet tender and affectionate—clothed all the universe, moral and material, with forms of grandeur, and gave to all he uttered the stamp of purity and truth. "His greatest faculty," says the most eloquent of his biographers, "was a half poetical, half philosophical imagination, a faculty teeming with magnificence and brilliancy; now adorning or aiding to erect a stately pyramid of scientific speculation, now brooding over the abysses of thought and feeling, till thoughts and feelings else unutterable were embodied in expressive forms, and palaces and landscapes, glowing in ethereal beauty, rose like exhalations from the bosom of the deep."

Of Goethe we have already so very fully expressed our opinion that we shall not again enter upon the subject. (See GOETHE.)

Tieck.

Uhland.

Koerner.

Grillpar

Müller.

Ruckert, Auersperg.

Ludwig Tieck is entitled to rank next to Schiller and Goethe. He may be considered as the head of the modern romantic in opposition to the classical school, delighting to let his imagination wander through the regions of mediæval fable and legend, and out of the material so gathered constructing edifices, airy indeed, and unsubstantial, but glowing like the clouds at sunset. His Genoveva and Fortunatus are splendid specimens of what has been termed the dramatic romance; and in some of the shorter pieces contained in his Phantasus there is much sprightliness and genial humour. As a translator of Shakspeare, he has won a high reputation both in his own country and in England. Ludwig Uhland (born 1787) has cultivated ballad poetry with more success than any recent author of Germany, and may be regarded as the most notable instance of the modern minstrel. It is true that he seldom or never rises to the heroic pitch, being somewhat deficient in energy. He cannot imitate the sound of battle or the clash of arms; but in the expression of the softer emotions he is eminently successful, and the flow of his versification is exceedingly graceful and melodious. The early fate of Theodore Koerner (1791-1813) has invested his writings with perhaps more interest than they intrinsically deserve. Yet it must be acknowledged that some of his lyrics exhibit much fire and enthusiasm, though the diction is occasionally extravagant. Franz Grillparzer, a Viennese poet, has composed some admirable dramatic pieces, the finest of which undoubtedly is King Ottocar, a noble historical tragedy, which may rank after the Wallenstein of Schiller. Wilhelm Müller's Songs of the Greeks are among the finest efforts of German poetry. Instinct with the true fire of enthusiasm, they are boldly conceived, and expressed with a nerve and energy strongly contrasting with the more feeble note and subdued diction of the recent poets, none of whom, if we except Ferdinand Freiligrath, seem to possess that inspiration without which verse is monotonous and tame. Ruckert and Count von Auersperg, better known by the poetical pseudonym of Anastasius Grün, have achieved considerable reputations, but they are only to be regarded as minor poets; and it is questionable whether their writings will maintain more than a temporary celebrity. From this sketch it would be wrong to exclude Adam Oehlenschläger the Dane, whose beautiful dramas of Coreggio and Aladdin are familiar to the English reader through the spirited translations of Mr Theodore Martin.

ENGLISH POETRY.

It is not our intention to enter into any minute details as to English poetry, with which we shall conclude the present sketch. Since we have already noticed, under separate heads, most of the individuals by whom it was adorned, we shall merely attempt to indicate generally the directions taken by poetical taste at different periods of our annals.

Even prior to the Norman conquest, we know from William of Malmesbury that England, like all the Gothic nations, had been possessed by a large mass of ballads, written in Anglo-Saxon, though, as no fragments of these remain, we know nothing of their poetical merit. This earlier minstrelsy must soon have sunk into discredit, or been entirely suppressed by the Norman conquest.

The English language, as it now exists, grew out of the mixture of the Anglo-Saxon with the Norman, and seems to have acquired a complete form by the middle of the thirteenth century. In 1297 we have the Rhyming Chronicle of Robert of Gloucester, the first undoubted composition in the English tongue.

From the Norman conquest to the time of Edward III., the literature and poetry of England consists of little else than translations from, or imitations of, the Norman romances and chronicles; and, judging from the ridicule with which they have been assailed by Chaucer in his Rhyme of Sir Thopas, they must have been of slender merit, since they are represented as shocking the taste, of course not particularly refined, of the host of the Tabard. The distance, at all events, which separates all our English versifiers of this period from Chaucer (born 1328, died 1406) is such as justly to entitle him to the honour of being the first of English poets, the sun that "flames in the forehead of the modern sky," throwing out a splendour that showed at once his own lustre and the dreary wastes that spread far and wide towards the literary horizon.

Chaucer.

Much of Chaucer's time, however, was wasted in the school of those French allegorical poets, whose romances were at one time so influential in Europe. In fact nearly half his life, as Mr Campbell remarks, was passed amongst the dreams, emblems, flower-worshippings, and courts and parliaments of love, of that visionary and tiresome school. He was fifty-four years of age before he commenced the Canterbury Tales, in which alone the peculiarities of his genius, its originality, and its extent, can be said to be completely manifested. This late discovery of the true bent of his powers is singular; for Chaucer appears peculiarly marked out as the poet, not of mysticism and allegory, but of clear observation of life and of practical aims. In the Canterbury Tales, which were obviously suggested by the influence of Boccacio's Decameron, he first found full scope for the display of the various qualities of his mind, and of that mass of real knowledge of life with which his experience of society in all its aspects, high and low, from the palace to the cottage, at home and abroad, had supplied his mind. His clear observation, and corresponding power of clear painting, giving the most vivid picturesqueness to all his delineations; his quiet and unobtrusive humour; his satirical power, at once forcible and delicate (a combination peculiarly rare in that stage of struggling and imperfect civilization); his imagination sufficiently elevated, yet always regulated by good sense; a cheerful contented tone of feeling, which makes him impartial towards all the world; a power either of creating character, or of so artfully and harmoniously putting together the result of his actual studies of men as to give to these all the free and natural effect of a creation; all these qualities found fit scope for their exercise in the broad varied canvas he selected, which, by means of its ingenious framework of a pilgrimage embracing persons of both sexes and of all ranks, and enlivened by tales told to relieve the tedium of the way, admitted equally of the comic and the tragic, the high and low; themes of chivalry and mythology, like the Knight's Tale; tales of wonder, blending oriental marvels with the romance of the West, like the Squire's; or stories of English low life, like the Miller's or the Reve's. The versatility of talent, indeed, displayed in the Canterbury Tales is astonishing; and, as in the case of his Italian rival Boccacio, it is difficult to say whether it is in the comic or the tragic that Chaucer most excels.

In invention, so far as regards incident, the English poet and the Italian novelist may be placed nearly on a par. The woodland freshness and beauty of Chaucer's forest scenes may be equalled by the charming country landscapes in which Boccacio places his interlocutors; but in power of characteristic delineation, particularly by those minute strokes of Dutch painting which present the exterior of objects, or those happily-selected traits which at once mark the individual, Boccacio cannot sustain the least comparison with the father of English poetry. He has many faults, but they are the faults of his age,—the faults of coarseness of taste and manners, of inartificial plans, of prolixity of style,—the natural errors to which the infancy of poetry, destitute of models, and struggling with an unformed language, was exposed. Against these must be placed the advantages of a vocabulary in which words are pictures, of subjects of description, unhackneyed, and bright with all their primitive freshness; the wisdom or grave humour of the philosophic observer blending most cunningly with the bonhommie and the garrulous graces of the narrator; an easy abandon, both as to matter and manner, which has its charm, however little reconcilable with the more artificial treatment which criticism would suggest; nature painted without exaggeration, as without disguise; and withal that feeling of unity imparted to the whole which makes the most discordant elements unite in kindly harmony, and which is never found except in the productions of the highest minds.

The appearance of Chaucer in English poetry has been well compared by Warton to the early appearance of a bright and genial day in an English spring; exciting the brighter hopes of a speedy and balmy summer,—hopes which are almost immediately blasted by the return of frost and tempest, and the settling down of winter, as bleak and blighting as before. In English poetry that effect was produced by the disastrous period of the wars of the Roses.

From the time of Chaucer, almost to that of Spenser, certainly no progress is made; or rather, if the language in some degree advances, the spirit of poetry retrogrades. Gower was his contemporary; Lydgate followed immediately after him; but they belong, so far as regards poetical genius, nay even poetical dexterity, to a previous century. In truth, the first introduction of learning into England appears to have been unfavourable to poetry, giving rise to pedantic imitation in place of independent efforts of genius,—a tendency which, indeed, to some extent, is visible even in the finest poetry of the Elizabethan period. Strangely enough, the hiatus which here occurs in English poetry was supplied by the nascent genius of Scottish writers, several of whom displayed no ordinary degree of accomplishment. The first of these in rank and time was James I. of Scotland, who, during his imprisonment in Windsor, is supposed to have studied and profited by the works of Chaucer. His principal poem, the King's Quhair, is composed in a dialect more refined than that spoken by his subjects, and contains many passages of real merit. His worthy successor was Robert Henryson, a moral and didactic poet, whose descriptions from nature are eminently beautiful. After him came Dunbar, who, in humour and power of character-painting, greatly surpasses Gower, and approaches to Chaucer. The poems of Surrey, and Wyatt, and Sackville, who followed during the reign of Henry VIII., can be regarded only as proofs that the love of poetry had not ceased to exist, and that in some shape, however rude, its voice was struggling to make itself heard in that calmer and more settled state of the political atmosphere which had followed the union of the rival houses in the persons of Henry VII. and Elizabeth of York.

Age of Elizabeth.

But when Spenser arose to enrich English literature with another great work of original genius, many causes, which had probably at first acted unfavourably for the progress of poetry, were beginning to exercise a more salutary operation. The Reformation, which had at first produced tumult, bloodshed, and wide-extended distress, by the suppression of those great hospitals, the monasteries, was now beginning to bring forth its better fruits, in the shape of a free and inquiring spirit, carried into all departments of thought and imagination. That acquaintance with the treasures of ancient learning, or the classic poetry of modern Italy, which had at first tended to overpower and confuse the national mind, was now turned to better account; it had insensibly refined the taste, and made the purest models of preceding times familiar to the poet and the scholar. The spirit of chivalry, still lingering in the English character, had been aroused into new and active existence by the triumphs which had attended the national arms during the reign of Elizabeth. A love of adventure had been generated by the frequent expeditions into remote countries and climes, as to which, in that imperfect state of geographical and physical knowledge, marvels were believed as incredible as any that figure in the pages of Sir John Mandeville. There was, in short, at this period, a remarkable union in the English character of the sober qualities of strong intellect with deep convictions and high imagination,—a character which manifests itself in every department both of poetry and literature.

Spenser.

Born in this happy period, and educated under such influences, Spenser (1510–1598) produced his great poem of the Fairy Queen. Familiar with Italian literature, as well as with the best learning of antiquity, it was from the works of Ariosto and Tasso that he had derived his bent towards chivalrous poetry. But the deeper earnestness of his character prevented him from treating his subject with the levity of Ariosto. Chivalry was to him a principle of faith, a part of religion, not the mere fantastic framework in which successive pageants of love and war, or luxurious description, were to be inclosed. In England it had not assumed that outworn and almost comic air which it wore when Ariosto first took up the entangled threads of Boiardo. It had still a vital influence on society, and ran like a thread of silver tissue through the coarser web of life. Nay, even the religious spirit in which Tasso had conceived the Jerusalem scarcely satisfied the mind of Spenser. He would render every incident which he described a step in some high argument or moral demonstration; every character the embodied representation of some virtue and vice; all the visions of imagination subservient to the cause of religion. He would enlist all the restless and excursive intellect and adventurous feelings of an ardent and romantic age under the banner of purity and goodness:—

> "That with the glory of so goodly sight,
> The hearts of men that fondly here desire
> Faire seeming shews, and feed on vain delight,
> Transported with celestial desire
> Of those fair forms, may lift themselves up higher,
> And learn to love, with zealous humble duty,
> Th' eternal fountain of that heavenly beauty."

And so deeply does this principle pervade his poems that, whilst wandering among the scenes of enchantment with which he surrounds us in that spiritual region to which he gives the name of Fairy Land, we can never forget that they have a spell beyond their first outward significance, nor be insensible to that still small voice of piety and wisdom which speaks through all those creations of his genius, and whispers that the place whereon we are standing is holy ground.

It must be admitted, however, that if this under-current of allegory gives a degree of solemnity and moral grandeur to Spenser's poem, its effects in other respects are unfavourable. It does occasionally interfere with the natural movements of the imagination, gives a formal and metaphysical air to the conceptions of the poet, and, by rendering the characters abstractions of moral qualities, impairs their individuality as human beings. So far, the injurious effect of Spenser's allegorical plan can hardly be denied; but it is absurd to speak of the allegory in Spenser being so obtrusive and continuous as altogether to destroy the interest of the poem as a representation of romantic life. The fact is quite different. Occasionally, no doubt, in the personifications of Envy or Pride, or the siege of the Castle of Temperance, in which the barriers of hearing, sense, smell, taste, and touch are represented as successively assailed by troops of monsters from without, the allegory is too prominent; but assuredly it sinks entirely out of view, and is perceived only on subsequent reflection, in the deep human interest of all the finer passages of the poem, such as the remorse of the Red Cross Knight; his temptation by Despair; the wanderings of Una, with her angel face "making a sunshine in the shady place;" Guyon's visit to the cave of Mammon, and his trial in the gardens of Acrasia; the combat of Cambel with the three brothers; or the many other passages which must be impressed upon the memory of every reader.

An extreme sensibility, almost amounting to a luxurious love of beauty, a flush of colour in his descriptions, which has led Mr Campbell to compare him to Rubens, and a fancy of the most remarkable exuberance, are the leading qualities of Spenser's mind. In this prodigality of fancy, indeed, lies at once the strength and the weakness of Spenser; for while it infuses life into all his pictures, making the plumes of Prince Arthur wave like the almond-tree on the top of Selinis; or the face of Britomart, when she raises her vizor, like the moon breaking forth in darksome night from behind the noisome cloud in which she was enveloped; so, on the other hand, it leads him occasionally to revel in images and traits which are painful, or even physically revolting, such as the portrait of Gluttony, the loathsome vomit of Envy, or the minute description of the operation of Diet and Appetite, Concoction and Digestion, with some other inmates of Castle Temperance. His fancy may indeed be compared to the Nile in its overflow, disdaining the confinement of banks, and spreading around a luxuriance of soil, alike productive of the flower and the weed.

In the portraiture of the allegorical beings introduced, Spenser is admitted to be without a rival. In his hand they almost cease to be mere abstractions of good and evil qualities, so life-like is the form in which they are presented, so picturesque the garb and accompaniments with which they are invested, so natural the gestures, actions, and occupations attributed to them. They appear the natural inhabitants of this realm of enchantment, raised as it is many degrees above the level of reality, bright in the near ground, with the sunniest tints of fancy, and fading away in the distance into the most aërial and heavenly hues.

The language of Spenser seems to be steeped in music; he is the greatest master of the difficult art of employing alliteration with success; his versification unites in the highest degree melody with majesty. It is formed on the principle of the Italian *ottava rima;* but, by the addition of the Alexandrine, it possesses a sonorous grandeur in the close which the Italian stanza wants. "It has not," says Mr Hazlitt, "the bold dramatic transitions of Shakspeare's blank verse, nor the high varied tone of Milton's; but it is the perfection of harmony, dissolving the soul in pleasure, or holding it captive in the chains of suspense. Spenser is the poet of our waking dreams; and he invented not only a language, but a music of his own for them. The modulations are infinite, like those of the waves of the sea; but the effect is still the same, lulling the senses into a deep oblivion of all the jarring noises of the world."

In the hands of Spenser, the allegorical form appears invested with all the brightest colours of the fancy. In the works of most of his contemporaries it appears lifeless and pedantic. No stronger instance can be shown of the tendency of imitators to copy the faults rather than the excellences of their master than is exhibited in the Purple Island of Phineas Fletcher. That poem, avowedly composed on the model of the Fairy Queen, with good diction and some choice imagery, is utterly intolerable from the absurdity of its allegorical conception. It is neither more nor less than an attempt to etherealize anatomy, and to strew the flowers of fancy over the grim realities of the dissecting-table. A disagreeable mixture of stilted expression and false learning blends with and alloys most of the poetry of the time. It deforms the otherwise noble lines of Sir John Davies, and renders Silvester unreadable. Shakspeare is not free from it; for it was deeply inwoven with the national taste of the time, and showed itself in the language of ordinary conversation no less than in poetry. Yet it is delightful to find the greatest dramatist also the greatest lyrical poet of his age; for, after Spenser, what work of that time will bear the least comparison with Shakspeare's sonnets? Sonnets they are not, in the strict sense; but for condensation of imagery, for natural thoughts, clothing themselves in the aptest expressions either of majesty or melody, without any redundance of expletives, or rank luxuriance of epithets, they leave Petrarch and his imitators at a distance. A singular grace, and even dreamy beauty, surprises us in the masques of Ben Jonson, because it contrasts so strangely with the otherwise hard and saturnine turn of his mind. A few gems, amidst much that is coarse or quaint or indifferent, may be gleaned from the pages of Herrick; power and vigour, mixed with sectarian gloom, and deformed by extreme ruggedness of versification, are visible in Quarles. The rise of satire appears in the works of Hall and Donne, of pastoral in Brown; while sacred poetry finds no unworthy representatives in Giles Fletcher and Crawshaw. A lighter and gayer taste, a more level but natural expression, shows itself in the compositions of the cavalier poets of the court of Charles I., in the graceful little airs and verses of Carew, Lovelace, Davenant, and Suckling. In particular, to them we are indebted for some of the best of the few good songs we possess in English,—witness the "He that loves a rosy cheek" of Carew, and the song written by Lovelace during his confinement in Westminster, "When love with unconfined wings hovers within my gates." To Denham and Waller, particularly the latter, have been ascribed by Johnson the glory of improving our English numbers. It would be more just to say that they had the good sense to perceive the importance of this element of poetry, as Spenser had done, while their contemporaries too much neglected it. Almost all the poets above mentioned have been classed by Johnson under the title of the metaphysical poets,—a title of doubtful application as to any of them, but which, if it be applicable to Cowley, whom he considers their chief, can scarcely be very accurate when applied to Suckling and Waller. Cowley is simply a poet in whom the fancy, while it is teeming and fertile, is seldom warmed by passion or directed by judgment; whose miscellaneous learning oppresses and buries his taste; and who therefore wearies us even at the moment he impresses us with the consciousness of his great resources and his mental powers.

Change produced by the civil war.

A great change in the character and spirit of poetry followed the convulsions which closed abruptly the reign of the first Charles. The poetry of that court leant towards the elegant, the romantic, the fanciful, the brilliant, and witty; but the stronger passions which had been awakened, the deeper interests which had been put in hazard, by the civil war, had soon impressed a character of solemnity on all literature, and made poetry itself, following the fashion of the time, assume a polemical, ascetic, sometimes mystical, yet grand and enthusiastic character. In those whose tastes were formed only after the change, this polemical character, and this proscription of certain subjects or associations to which Puritanism led, would probably have damped the wing and narrowed the flight of imagination; and, accordingly, no great poet appears to have been reared in that rigid and prosaic school. But the tastes of Milton, the great poet of this period, had all been formed in an age and a school more favourable to the exercise of the imaginative powers; his exquisite lyrics, and his Comus, had already been written before he visited Italy in 1638, at the very time when Carew, and Suckling, and Davenant were in the height of their popularity and reputation. Ere his great epic poem appeared, he had witnessed and deeply shared in the agitating struggle which had ended in the temporary subversion of the monarchy, and the stern but imposing despotism of Cromwell; and thus educated in the former period, and as yet witnessing the best bloom and flush of the latter, he united the chivalrous recollections of the Elizabethan age, and the classic associations with which his early education had filled his mind, with the enthusiasm of principle and intensity of will which characterized the men of the Parliament. Milton represents more vividly than any other the wide sweep and overpowering force of those political and religious sentiments which agitated the age; for all his earlier leanings were visibly directed towards the romantic and gorgeous associations of the past, towards the pride and pomp of chivalry, the well-trod stage, the throngs of knights and barons bold, the stateliness of feudal castles, the solemnity of minsters, the pomp of tournaments, the peal of organs, and the dim religious light of painted windows. Such was the poet of Lycidas, of Comus, of the Allegro, and the Penseroso, the two most perfect gems of contemplative lyric poetry of which Britain has to boast; and yet we see these tastes abandoned or repressed as he advances in life and in party spirit, till at last he views them only as unnatural corruptions of primitive liberty and simplicity. Still, with Milton, though a taint of bigotry pervades his views, everything is pure, high-minded and disinterested. "Nought he does in hate, but all in honour." He stands at an immense distance from the sect to whom he had allied himself, but with whom, after all, he had little in common. In no one does poetry more conspicuously appear a part of religion. He regards it as a sacred trust, not to be sacrificed on the altar of vanity, not to be purchased for a price, not to be applied to any unworthy or even trifling end:—

> "Driving far off each thing of sin and guilt,
> And in clear dream and solemn vision
> Telling of things which no gross ear can hear;
> Till oft converse with heavenly habitants
> Begin to cast a beam on the outer shape,
> The unpolluted temple of the mind,
> And turn it by degrees to the soul's essence,
> Till all be made immortal."

It would be absurd, at the present day, to enter on any formal criticism of his great work of Paradise Lost, the most original, if not the most successful, of modern epics. About no poem perhaps are opinions more agreed; every one feels its sustained loftiness, combined with so much of tenderness, in the scenes of Eden, but always suggesting the idea of effort and labour,—the wonderful art with which learning itself is rendered poetical in his hands; for even the visions of mythology and the fantastical traditions of chivalry are made to heighten the effect of a sacred poem dealing with the mystery of the fall of man; and, lastly, the consummate artifice of the versification, which, as Hazlitt remarks, seems to float up and down, as if on wings.

Butler. Milton represents the more imposing side of the Puritans, and he is almost the solitary poet of whom they can boast. The other side of their character, their hypocrisy, and their narrow and coarse tastes, are exposed in the merciless and consummately clever Hudibras of Butler. That poem is now, no doubt, in a great measure obsolete, like every application of poetry to the exposure of the peculiarities or vices of a particular age; yet its masculine vigour, its condensation of thought, and its wit, entitle Butler to a very high rank among the broad humourists of poetry.

Dryden. From the oppressive wit and subtlety of Cowley and his fellows it is delightful to turn to the manliness, the common-sense, the "long-resounding march and energy divine," of Dryden, who marks the point of transition from the metaphysical poetry to the critical. He had himself in youth been strongly influenced by the prevailing taste for conceits; and it must be admitted that in the greater part of his dramatic writings this taint clings to him to the last. As a dramatist, indeed, we can admire in him nothing but the nerve and vigour of his dialogue, and that power of reasoning in verse in which he so much excelled. But in his other works, such as the Absalom and Achitophel, he threw aside this rage for conceits; he was natural, transparent, vigorous; his illustrations, instead of being sought for, as in the case of Cowley, on account of their remoteness and apparent inaptitude, are such as at once adorn and elucidate, and are felt to be close and familiar without being common. High imagination he did not possess, and for his purpose it was scarcely needed. He has, in fact, scarcely written a line which is pathetic, and few that can be considered sublime. Yet in fancy he was not deficient, for it supplies him with inexhaustible imagery; his Ode shows that he could be raised at times into a true lyrical enthusiasm, whilst his judgment rarely fails him except indeed in those bombastic plays which he had framed by jumbling together an imbroglio of two inconsistent models—the French school, from which he borrowed his rhymes and his affectation of sentiment, and the Spanish, to which he was indebted for the exaggeration of his passionate scenes and the complexity of his plots. Had he known nothing of these, and been left to form himself on the model of Spenser, and Milton, and Shakspeare, and in a less artificial state of society, he might at least have avoided the gross want of nature evinced in these rhyming plays, though we can hardly persuade ourselves that, by any process of tuition, he could ever have become a great dramatist. "The general soundness and healthfulness of his mental constitution, his information, of vast superficies though of small volume; his wit, scarcely inferior to that of the most distinguished followers of Donne; his eloquence, grave, deliberative, and commanding, could not save him from disgraceful failure as a rival of Shakspeare, but raised him far above the level of Boileau. His command of language was immense. With him died the secret of the old poetical diction of England, the art of producing rich effects by familiar words. In the following century it was as completely lost as the Gothic method of painting glass, and was but poorly supplied by the laborious and tesselated imitations of Mason and Gray. On the other hand, he was the first writer under whose skilful management the scientific vocabulary fell into natural and pleasing verse. In this department he succeeded as completely as his contemporary Gibbons succeeded in the similar enterprise of carving the most delicate flowers from heart of oak. The toughest and most knotty parts of language became ductile at his touch. His versification, in the same manner, while it gave the first model of that neatness and precision which the following generation esteemed so highly, exhibited at the same time the last examples of nobleness, freedom, variety of pause, and cadence."[1]

Pope Pope is the last great writer of that school of poetry, the poetry of the intellect, or rather of the intellect mingled with the fancy, which occupies the period from the Restoration to the close of the eighteenth century. In Dryden's satires and miscellaneous poems we perceive the reasoning poetry brought to its perfection, as far as regards vigour of conception and force of expression. In these respects nothing remained to be added. But Pope possessed that quick tact and intuitive discernment, both of the range and limit of his own powers, and also of the taste of the age, which showed him the solitary direction in which, so far as regarded this philosophic and critical school of poetry, there yet remained an opening for himself. He felt that the qualities of his mind did not fit him to surpass, and scarcely to contend on equal terms, with Dryden, so far as regarded grasp or force; but he conceived that, in the way of polish, refinement, grace, and choice of expression, something yet remained to be done, and that something he was able to afford. Selecting, by a natural preference, themes of a moral and didactic rather than passionate character, adopting the idea, that everything should be polished to the highest pitch, and that artifice was the fundamental principle of poetry, that artifice, he thought, could hardly be carried too far; and, accordingly, with Pope we find habitual that attention to words which is only occasional with Dryden. If in Dryden we perceive a tendency to substitute logic and reflection for feeling, to exhibit pictures of conventional and artificial rather than of general nature, and to borrow his illustrations much oftener from science and art than from natural objects, this tendency appears still more decided and uniform in Pope, who is pre-eminently the poet of a period of high intellectual culture and limited poetical sensibilities,—the poet who wrought to its last perfection the pure but limited vein which this contemplative and preceptive style of poetry afforded. After Dryden nothing new could have been achieved for this style of poetry save what has been done by Pope; and what he attempted he perfected.

It is indeed impossible to award to him a rank in poetry of the same kind with that which had been occupied by our Miltons, Spensers, and Shakspeares. In the highest departments of poetry, the epic and dramatic, he has attempted nothing. In the lyrical he has failed. In translation his example has tended to corrupt the national taste, and to substitute a glittering, false, and metaphrastical version for a true translation. His forte is essentially the didactic and satirical; moral instruction or censure enforced with all the charms or all the point of which such subjects are susceptible. Within that range he has never yet found his equal; for to the logical and reasoning power and condensation of Dryden and of Boileau, he adds at times, as in his Rape of the Lock, an excursiveness and brilliancy of fancy—a compact strength with perfect harmony—a quiet, graceful, continuous humour, altogether without parallel. Yet, whilst speaking of the harmony of his versification, it must be added that he carried this principle to excess; that his system of terminating the sense invariably with the line, and his pauses, placed almost always on the fourth or sixth syllable, led to a monotony the most painful when contrasted with the varied pauses and lines flowing into each other, which were so happily employed by our elder writers; and that, finally, in regard to rhymes, Pope, though he was singularly limited as to range, was even within that range far from correct.

---

[1] *Edinburgh Review.*

Prior.

"The best," says an eminent critic, "of what we copied from the continental school is copied in the lighter pieces of Prior. That tone of polite raillery, that airy, rapid, picturesque narrative, mixed up of wit and naïveté, that style, in short, of good conversation, concentrated into flowing and polished verses, was not within the vein of our native poets, and probably never would have been known among us, if we had been left to our own resources. It is lamentable that this, which alone was worth borrowing, is the only thing which has not been retained. The tales and little apologues of Prior are still the only examples of this style in our language."

As we advance through the eighteenth century, we perceive that the critical school of poetry had evidently attained its perfection in Pope, and was destined, at no distant period, to sink into mere prose, disguised under the appearance of verse. At least, after Pope, there is a visible decline, until the appearance of the first germs of a new taste, with which the intellect had less to do, whilst the feelings obtained a more decided supremacy.

Addison, Swift.

Addison's poetry is so flat, and cold, and destitute of imagination, that, but for the exquisite grace and refined taste of his prose works, it would not now be mentioned; and Swift, though a most clever versifier, and endowed with no ordinary talents for libel in the shape of epigram or satire, can hardly, by any stretch of favour, be regarded as a poet.

Thomson.

The first symptoms of the change which had been gradually going on appears in the return to a taste for simple instead of artificial nature; for as yet the revival of strong feeling or passion would have met with no sympathetic feeling on the part of the public. In Thomson are to be traced the first symptoms of the reviving taste for the "simple-natural." True it is, his field is limited. When he attempts narrative, when he indulges in properly didactic poetry, his style appears cumbrous, and his ideas commonplace enough. "*Liberty*," says Dr Johnson, "when it first appeared, I tried to read, and soon desisted." Few at the present day will even make the trial. But when he comes to deal with the matters which lie within his proper sphere, and are congenial to his quiet, contemplative, and indolent turn of mind, he is an original and a striking poet. We must never forget, in speaking of Thomson at the present day, that his poem was the first of its kind, and even yet, like Milton's Eve, it is the fairest of its daughters. Even now we must admire the painter-like skill with which, in his rural descriptions, he selects his point of view, the art with which he seizes the characteristic, and drops the less marked features of the landscape; the infinite variety of little circumstances connected with animate and inanimate nature, unnoticed by his predecessors, but which his quick tact detects and sets before our eyes; the soft, bland, Claude-like glow which he spreads over all he touches; the spirit of love and benevolence, and philanthropy, which he awakens; qualities which give to his Seasons a fascination which, though felt most strongly in childhood, is yet not materially abated by the judgment of cooler years. His faults are cumbrousness of diction and occasional vulgarity of taste.

Goldsmith.

The same sweet and natural tastes, though of a more refined kind, the same philanthropical spirit, and the same gentle inspiration of poetry are visible in Goldsmith. He has not indeed Thomson's sympathy with the sublime and terrible in nature; his mind habitually turned towards its milder and more smiling aspects, the fertility and richness of cultivation, the tranquillizing tone of village life, "the short and simple annals of the poor." "He is refined," says Mr Campbell, "without false delicacy, and correct without insipidity. Perhaps there is an intellectual composure in his manner, which may in some passages be said to approach to the reserved and prosaic; but he unbends from this grave strain of reflection to tenderness, and even to playfulness, with a peculiar grace, and connects extensive and philosophic views of the happiness and interests of society with pictures of life that touch the heart by their homeliness and familiarity. . . . His whole manner has a still depth of feeling and reflection which gives back the image of nature unruffled, and minutely. He has no redundant thoughts or false transports, but seems on every occasion to have weighed the impulse to which he surrendered himself; and whatever ardour or casual felicities he may have thus sacrificed, he gained a high degree of purity and self-possession."

Blair, Ramsay.

The names of Blair and Ramsay deserve notice, the first as the author of a poem, gloomy and homely, but with a decided character, and a picturesqueness of imagery, which redeem it from vulgarity, and which have been justly compared to the powerful expression of a countenance without regular beauty; the latter as a writer of a true pastoral drama, in a style totally different from the hackneyed mythological models on the subject, and delineating the natural and simple manners of the peasantry of Scotland, with a truth, a comic archness and tenderness, which entitle the author of the Gentle Shepherd to an honourable rank in British poetry.

Savage, Chatterton.

A mournful interest attaches itself to the names of Savage and Chatterton, both the victims of misfortunes caused, in some degree, by their irregularities of conduct or deficiency of principle. In the latter, in particular, the seeds of a mind of considerable power are evidently discernible, choked indeed with many rank weeds of evil tendency, but which, pruned and weeded by years and experience, might have rendered him an ornament to the literature of the eighteenth century.

Collins.

Collins wrote but little, yet that little was of first-rate merit. His Oriental Eclogues may be regarded as only a boyish production; but the rest of his lyrics suffer only by comparison with those of Milton, and that chiefly through a certain obscurity of diction, into which he was led by endeavouring to avoid the commonplaces of expression. In proportion to the neglect which they encountered on their first appearance has been their popularity since. The Ode to the Passions, in particular, has become a universal favourite, by its admirable personations, the flush of beautiful colouring with which it is invested, and the richness of the versification, which adapts itself with such art to the themes of sadness and gaiety, or deep gloom, which alternate throughout the poem.

Churchill, Akenside, Dyer, Armstrong, Shenstone, Falconer, Glover.

There is strength and nerve, but nothing more, in the ferocious satires of the dissipated Churchill; an undeniable, though very often turgid and unsubstantial grandeur about Akenside's Pleasures of the Imagination; but there is also perfect truth in Johnson's remark, that the words are multiplied till the sense is hardly perceived, and that attention deserts the mind and settles on the ear. Some pleasing pictures in Dyer and Armstrong, and a natural grace in Shenstone (which, however, sometimes borders on childishness), will preserve a certain popularity to Grongar Hill, the Art of Preserving Health, and the School-Mistress. The merits of Falconer's Shipwreck have, we think, been overrated. Its technicalities frequently appear tedious, and few poets have dealt more in needless expletives and mere commonplaces of description. Of Glover, whose Leonidas was once compared to Milton's Paradise Lost, the world now remembers nothing except his clever ballad of Hozier's Ghost.

Young.

Young is a poet of more fire, and of a decided though perverted ingenuity. He exhibits a curious mixture of the style of Queen Anne's day with the more pensive and meditative cast of our own. Few poems could be pointed out in which so much point, rare wit, and brilliancy, have been employed with so little effect. The whole poem is a long epigram, a string of hyperboles. It is precisely such a work, indeed, as we should expect to be produced by a person, naturally of a cheerful turn of mind, putting on, for the sake of effect, the garb of melancholy, and misanthropy, and weariness of existence; and composing, as he is said to have done, by the light of a candle stuck into a human skull. It has the worst points of Lord Byron's manner, without the earnestness and verity of that feeling of weariness of the world which speaks throughout Childe Harold.

Gray, in the delicacy, the classical neatness, and polish of his verses, is closely associated with the writers of the age of Anne. There is no doubt a certain want of ease and spontaneity about Gray; his inspiration seems to flow slowly; he rises with compulsion and laborious flight. His poetical fire seems often cold and phosphorescent; but he has a fine sensibility to the beautiful and sublime, a mind richly stored with the beauties of the classical and Italian poets, and he has combined his ideas of invention and recollection in a mosaic of singular delicacy and compactness.

Beattie.

In the Minstrel of Beattie some of the features of modern poetry become discernible, in its stronger sympathy with nature; nay, even in the general idea of the poem, which describes the solitary growth of a romantic and poetical spirit, and which possesses high merits as a sweet picture of still life, and a vehicle of unobtrusive morality.

Cowper.

But the complete transition from the artificial style of the writers of Queen Anne to that which characterized the poetry of the opening of the present century, first appears visible in Cowper; who, throwing aside the trammels of artificial refinement, and the imaginary requisites of a conventional poetical diction and classical imagery, ventured to write as he thought, with the force and freedom of an older and a better time. In no poet of the last century did a more vigorous and original cast of mind present itself; and to no poet are we more indebted for awakening that freer and more forcible spirit, that poetry of the heart rather than the head, which has formed the marking feature of our own times. His satirical and didactic poems, though abounding with wit, and animated by the eloquence of conviction, are indeed deformed by many defects, both of indifferent poetry and bigotry of opinion; but in his descriptive poetry, in his charming pictures of in-door life, his summer and winter landscapes (so different from Thomson's, by their minute detail), in those bursts of inspiration which occasionally escape the poet, as in that where he addresses the stars in the fifth book of the Task, he has left us some of the most touching and spirit-stirring passages of which the eighteenth century has to boast.

Burns.

The same spirit appears, in Scotland, in the deep tenderness of the lyrics of Burns. Much of his poetry, doubtless, can only be remembered with regret, as the effusion of a reckless and ungoverned spirit, mistaking coarseness for force, and confounding genius with extravagance and irregularity. But he has left behind him a few strains which are of a higher mood, nay, of the very highest order; familiar and yet noble, tender and yet manly; such as a peasant only could have written, but a peasant who was one of nature's nobles. "Scotland," says an American critic, "owes a large debt of gratitude to Burns; for he invested the feelings and sentiments of its peasantry, their joys and sorrows, with dignity and beauty; he redeemed their language from neglect, if not from contempt; he made the heart of every true Scot burn within him as he thought of the hills and valleys of his native land; he first guided the footstep of the pilgrim to the scenes of her traditionary glories, and he sung those glories in strains so simple, yet sublime, that the world stood still to listen."

Although in the poetry of Burns there are abundant traces of that stern force and strong passion with which we have been of late rather too familiar, the general tone of the poetry of the eighteenth century may be described as quiet and contemplative. But the great and terrible events which darkened its close, exciting the minds of men throughout Europe, introduced into the literature of all nations a spirit of restlessness and doubt, a love of strong agitation and stimulus, which either manifested themselves in a longing retrospection and veneration for the past, or in wild discontent with the present, and delusive visions of the future. This tendency appears in the publication of our ancient ballads, and the enthusiastic admiration which their rough vigour, their simple pathos, and their spirit-stirring pictures of love or war awakened; in the undiscriminating republication and study of our older dramatists of the school of Shakspeare, and our lyrical poets of the period which immediately followed; in the popularity and influence which the works of Goethe and Schiller, stamped with the character of the time, immediately obtained, when introduced to us through the means of wretched translations; and in that mixture of scepticism, moody discontent, and wild enthusiasm which had been painted in such gloomy and forcible colours in the Werther, the Faust, and the Robbers.

Scott.

But waters, however turbid, soon run themselves clear; and it is to the credit of the English poets who adorned the first half of the nineteenth century that they did not, through imitation, or from a wild craving after originality, rush headlong into extravagance. Original they undoubtedly were. At no other era of our literature do we find so many eminent poets pursuing separate paths, and professing different theories of art with so much individual success. Indeed it may be said that the practical examples of the last fifty years have done much to shake the public faith in the infallibility of all literary canons as applied to poetry, so various, nay, so discordant, have been the means employed by the great masters in achieving their renown. The first poetical name in point of date, perhaps also in point of merit, is that of Sir Walter Scott. No doubt his claim to pre-eminence will be disputed by those who prefer poetry of a reflective kind to that which is purely objective, by those who regard careful and polished versification as an absolute essential, and by those who seek for excitement rather in the portraiture and anatomy of morbid passion than in scenes of stirring action. The warmest admirers of Scott must admit that he is neither didactic in his tone, nor elaborate in his verse, nor a subtle delineator of shades of mental difference. His characters are broadly sketched, but that breadth makes them, in our opinion, particularly well fitted for practical use in poetry such as his, the characteristic of which is action. By refining or over-minuteness in these respects, he certainly would have lessened the effect which he produces through rapidity of motion; for his narrative may be aptly likened to a stream so impetuous that the characters are borne away with it, affording us but occasional glimpses as they rise or sink with the current. With Scott the narrative is all in all. We think little and care less about William of Deloraine, as we accompany him in his headlong ride from Branksome to Melrose Abbey; we are bent on the progress of the tale. Marmion is less the hero of the poem than the ideal spectator, through whom or with whom we listen to the legend of the elfin knight who haunts the deserted camp, or survey the Scottish army encamped on the Borough Muir, or mingle in the revelries of Holyrood, or plunge into the fight at Flodden. Action and descriptive power, which latter quality he possessed to a great though not superlative degree, are Scott's grand excellences; but these surely must be ranked among the highest of poetical attributes; and if lasting popularity is to be taken as the test of merit, Scott is entitled to the first place among his contemporaries: indeed it is doubtful whether his poetical reputation has not been somewhat obscured by his greater fame as a writer of romance, in which department he stands, by universal acclamation, without a rival.

Byron.

Next we shall notice Lord Byron, gifted with a greater versatility than any modern author, not even excepting Goethe. But his temperament was uncertain, his mind ill-regulated, his judgment vacillating, and his passions uncontrolled. Wanting in self-respect, and setting opinion at defiance, he attempted, nevertheless, by a *coup-de-main*, to storm the heights of fame; and he did so successfully, though without effecting a permanent occupation. He was like a comet, which, while it flares in the midnight sky, attracts more attention than the planets, but which, after reaching its perihelion, declines in splendour and in glory. And yet few poets, limited to so short a life, have done so much. We are inclined to think that his error lay in attempting so much without that concentration and thought which is necessary to make perfect the efforts of genius. His main object was to astonish the public of the day, not to produce real works of art; and, in default of inspiration, which every true poet ought to feel, he trusted to his natural gifts, which, great as they were, could not bear him successfully through so many different experiments. But his worst fault was the frequent obtrusion of a scoffing and irreverent spirit, a parade of sarcastic mockery which jars upon the feelings, and too often neutralizes, or rather destroys, the effect of passages which otherwise were calculated to charm or delight. Even while acknowledging his genius, we are compelled to deplore its abuse. Hence the reputation of Byron since his death has visibly decreased. We are no longer dazzled with its fulness. As the ebb of the tide reveals rocks, and shoals, and quicksands, so have the many faults and imperfections of Byron become apparent to the eyes of the new generation. Still, beyond these and afar off, they behold the clear water, with the sunlight playing on its surface.

Wordsworth.

The poetry of William Wordsworth has given rise to much literary discussion. Popular it never was, in the extended sense of the word, but it found many and ardent admirers; and men of high intellect and critical acumen were vehement in its praise. Others, who maintained the contrary, were almost as vehement in their censure. When such a controversy occurs, we may very safely conclude that there has been exaggeration on either side, and that the poet is neither entitled to the high rank claimed for him by his adherents, nor properly to be placed in the low grade which his detractors would grudgingly assign to him. The poetry of Wordsworth is widely different in its kind from that of Scott and Byron. It is essentially contemplative and philosophical. Never, perhaps, did any writer show himself so averse to action. In one only of his longer poems, the White Doe of Rylstone, has he attempted anything like a narrative, and there the story moves as painfully and slowly as a paralytic cripple upon crutches. His chief poem of the Excursion certainly does contain some noble passages of a reflective cast; but it is, as a whole, intolerably tedious, not possessing sufficient interest to carry the reader along, and being interspersed with platitudes in heavy verse, from which it is impossible to derive either instruction or pleasure. Upon his minor poems, his odes, and sonnets, his real fame must rest; and many of these are of rare merit, some deserving to be ranked as masterpieces. His Laodamia and Ode on the Immortality of the Soul are amongst the finest productions of the English language; and some of his ballads, though always deficient in spirit, are, from their tenderness and simplicity, very touching. One remarkable feature in the mental conformation of Wordsworth was the total absence of the sense of humour. Nothing ever appeared to him to be ludicrous. Associations which might have forced Heraclitus to laugh, could not extract from him a smile. This dulness of perception, for such it was, led him in some instances to disfigure his compositions by the introduction of images and objects so very mean as to be unfit for poetical use, thus exciting the risibility of the reader, and in some degree lowering the respect which otherwise would have been accorded to the bard. In our opinion, sufficient allowance has not been made for this defect, which was the real cause of much hostile criticism. Wordsworth, however, was not singular in that respect; for other poets of a high grade, among whom we may specify Milton, were deficient in the sense of humour. We must also remark that Wordsworth's habits of composition were such as, in a great measure, to justify the censure of his critics. He was essentially an egotist, with a firm and unshaken belief in his own powers at all times and at all seasons. He had no idea of waiting for afflatus, impulse, or inspiration. He conceived that in his ordinary mood he could at any time compose verses worthy of being received by the public with as much reverence as the ancient utterances of the Sibyl; and accordingly he spun out a certain daily number with the unflagging industry of the silk-worm. However laudable such diligence may be in ordinary literary manufacture, it is quite plain that it is not applicable to the production of poetry, which, as we have said in the commencement of this article, attains its end by the use of language natural in an excited state of the imagination and the feelings. It is necessary, therefore, to make a distinction between Wordsworth the versifier and Wordsworth the poet. In one capacity he has been excelled by many: in the other he has been equalled by few. But the bulk of his verse as compared with the bulk of his poetry is enormous.

Southey, Coleridge, Campbell, Moore, Crabbe, Shelley.

Robert Southey, the most industrious writer of his age, had very large poetical capabilities, but he also wrote too rapidly; and being somewhat of a theorist, was too much addicted to making experiments in verse. His longer epics have already ceased to attract much of the public attention; but we venture to predict that one of them, The Thalaba, will hereafter be greatly prized. It is a magnificent oriental tale, expressed in beautiful and glowing language, most wonderful in the harmony of its verse, and abounding in pictures so vivid that the art of the painter could hardly heighten their effect. The fame of Coleridge, challenged during his lifetime, is now universally admitted. The weird Rhyme of the Ancient Mariner, Geneviève, the Hymn in the Valley of Chamouni, and his noble translation of Schiller's Wallenstein, are too widely known and appreciated to require commendation. Of Campbell we have already spoken in the article specially dedicated to his biography. Thomas Moore, the poetic jeweller of the period, whose skill in the manufacture of glittering gewgaws was unrivalled, will probably remain a favourite with readers of that class and age who have a decided propensity for *bijouterie*. We ought earlier to have noticed Crabbe, the poet of humble life, who belonged as much to the past as to the present century, his first work having been revised by Samuel Johnson, though he died in the same year (1832) as Sir Walter Scott. Strong nervous power and clear delineation of character, with almost microscopic minuteness, were his distinguishing characteristics. Percy B. Shelley was a phenomenon, of whom we may not see the like again. He was a pure heathen, much resembling Lucretius in character and genius, without faith in revelation, blind in the midst of light, yet, like the *clairvoyants*, claiming an occult faculty of vision. His versification is most melodious; and his thoughts, usually tinged with melancholy, are, when not applied to interdicted themes, remarkably attractive. Some of his lyrical pieces are certainly destined to endure.

Keats. We close this necessarily brief notice of the more recent English poets with the name of John Keats, a poet who, during his short life, was most unjustly assailed, but whose reputation has gradually but securely risen. His first poem, the Endymeon, was full of faults. It was crude, unequal, and in some parts even prurient; nevertheless, it is impossible to peruse it without feeling that it was the production of a genuine poet. Scholars sneered at it, as something quite alien from the spirit of mythology; and so perhaps it was; but Keats had studied in the school of Chapman and Shakspeare, and, with the natural audacity of youth, thought himself qualified to tread upon any ground however sanctified by ancient consecration. The rebuke which he received was certainly too severe for the offence. But he afterwards gave to the world several poems regarding which there can be no doubt or cavil. The Eve of Saint Agnes is a gem of pure lustre and exquisite workmanship; and Hyperion, though only a fragment, is a splendid specimen of versification, and indicates an epic power, which, though it possibly might have failed in a sustained flight, as the pinions of Icarus melted under the influence of the sun, must ever be regarded as a noble effort cut short by the hand of death.

Wilson, Hogg, Hemans, Cunningham. Other poets there were who, had they flourished in the last century, would have acquired more fame than is likely to be accorded to them in a period when so many great reputations were jostling each other. John Wilson, the renowned Christopher North, whose prose writings are imbued with the noblest spirit of poetry, has, in his City of the Plague, and Isle of Palms, left traces of true genius. James Hogg, better known as the Ettrick Shepherd, was a poet of no mean capacity; indeed his Kilmeny stands by itself as a rare and wondrous poem: Felicia Hemans, in point of sweetness and delicacy of sentiment, has rarely been equalled by any of her sex; whilst to Allan Cunningham we must accord the praise of a lyrical power not much inferior to that displayed by Burns. We might greatly extend the catalogue; but, like Tarquinius Superbus, we can only deal with the taller poppies. With regard to living poets, any praise or censure of ours would be irrelevant and unbecoming. (G. M—R.) (W. E. A.)

POGGIO. See BRACCIOLINI.

POILLY, FRANÇOIS, a very eminent French engraver, was born at Abbeville in 1622. His enthusiasm for his art was very great. After receiving the first principles of engraving from his father, he applied himself for three years under Daret at Paris. Then repairing to Rome, he laboured assiduously for seven years, improving his design and executing several plates after the great Italian masters. No less was his assiduity when he had settled in the French capital with the reputation of being one of the best engravers of his native country. He continued to handle his burin at once with care and dexterity, and to superintend the labours of several pupils; so that at his death in 1693 his prints amounted to about 400. A list of the principal plates of Poilly is given in Bryan's *Dictionary of Painters and Engravers*. The most popular of these are "San Carlo Barromeo administering the Communion to the Persons infected with the Plague," after Mignard; "The Holy Family," after Raphael; and "The Flight into Egypt," after Guido. Poilly's younger brother Nicholas, and his nephew Jean Baptiste, were also distinguished engravers.

POINT. See PUNCTUATION, GEOMETRY, ASTRONOMY.

POINT-A-PITRE. See GUADALOUPE.

POINT DE GALLE, a fortified seaport-town of Ceylon, stands on a peninsula on the S. coast of the island, 70 miles S.S.E. of Colombo. Its appearance from the sea is very striking and picturesque. At the eastern extremity the solid old fortifications rise from the edge of the surf-beaten rock. At the other end is the quay, with numerous canoes always about it; and not far off are the white houses of the natives, overshadowed with trees. Most of the Europeans live in the fort. Behind the town, at the distance of 700 yards, rises a chain of hills covered with verdure and trees to their summits. Point de Galle has a mosque, several churches and schools, a lighthouse, and a large cinnamon garden. The inner harbour gives shelter to large vessels quite close to the town; and it is commanded by the fort. There is also a large roadstead in the bay. An active trade is carried on in cotton, coffee, cinnamon, ivory, &c. The mail steamers from Aden to Calcutta and China call at Point de Galle.

POIRINO, a town of the kingdom of Sardinia, in the division of Turin, on the left bank of the Bonna, 14 miles S.S.E. of Turin. It contains two old castles, several churches, a court-house, school, convent, and hospital. Pop. 5668.

POISON, any substance which, acting on living bodies in small quantities, occasions serious disturbance of their functions, and may cause death. The science which treats of poisons is termed toxicology.

Poisons have been known from remote antiquity; but the notions entertained of their effects were generally fanciful and vague, so that it is often impossible now to discover what the poisons of the ancients really were. In modern times a great addition has been made to our knowledge of them, both as regards their number and their action; and it is only within the last forty years that the nature and the varieties of their action have been studied scientifically and with success.

The number of poisonous substances now known is very great; and there can be no doubt that very many still remain to be discovered, equally in the mineral, the animal, and the vegetable world, but more especially among vegetables. Numerous, however, as they are, they present many remarkable agreements in their effects or actions, so as to admit of convenient classification.

Action. Some poisons produce no other effects besides what depend on the local injury they give rise to. Of these, some produce by their chemical properties absolute destruction of the textures to which they are applied; and the result depends in part on the nature and degree of the injury, but as much on the importance of the injured texture, and its sympathetic connection with other parts of the body. The mineral acids, such as sulphuric and nitric acid, and the mineral alkalis, potash or soda, are the best examples of this kind. Others, again, of those which act locally alone, produce inflammation, but not chemical destruction, where they are applied; and all the ordinary effects of inflammation may ensue; of which gamboge and colocynth are good illustrations. The action of the former description of local poisons does not differ essentially from that of mechanical injuries of the same textures; the action of the latter is almost identical with that of the natural causes of inflammation. A third description of local poisons merely produces a peculiar impression on the nerves of the part to which they are applied, without either destroying or inflaming its texture. But there is no pure instance of the kind yet known; all such poisons likewise act otherwise than locally. Opium and prussic acid are examples.

Other poisons, and these by far the most numerous, act upon remote organs and textures,—on parts to which they are not, nay, cannot be, directly applied; and effects of this kind are often developed without any appreciable signs of a direct local action. There is scarcely an important organ in the body which may not be brought thus under the influence of some poison or another. The brain is very often so affected, as by opium, belladonna, prussic acid, and charcoal fumes. The stomach and intestines are also frequently affected indirectly, as by arsenic. The spine is affected by nux-vomica, the kidneys and bladder by cantharides, the lungs by tartar-emetic, the heart by oxalic acid, the liver by manganese, the salivary organs by mercury, and many of the glands by iodine. Many poisons possess the property of acting on a great number of organs in this remote or indirect way, of which arsenic and mercury are the most remarkable instances. Arsenic introduced by the skin has been known to act on the stomach, intestines, kidneys, heart, the lining membrane of the eyes, nose, windpipe, and vagina, the nerves of voluntary motion, and the skin at a distance from its place of application. Physiologists are still in some doubt through what channel these remote effects are produced,—some believing that the poison is carried in substance with the blood from the organ to which it is applied into the parts on which it acts; others, that the operations are merely nervous, and consist of the transmission of certain local impressions along the nerves which communicate between one organ and another; and others, that both modes of action may exist, even for the same, and still more for different, poisons. The first of these views is the one most generally held. Two facts, however, are clearly established, whatever theoretical deductions may be drawn from them:—1*st*, That very many poisons do enter the blood, and may be detected there; and 2*d*, That these never enter except in minute proportion, so that, unless very delicate tests are known for them, they may readily escape detection. It seems not improbable that some poisons are deposited by a species of election in particular organs; but of course their presence in the blood will give them access more or less almost everywhere, since there are few organs not traversed by blood-vessels, and minutely injected with blood.

The greater number of poisons produce their peculiar effects through whatever texture they are introduced into the body. The effects of local poisons greatly depend, as was already stated, on the texture to which they are applied; but the far more numerous denomination of poisons which act remotely exert that action to whatever part they are applied, provided they fairly enter the body. They enter the sound skin with extreme difficulty, but most easily in the form of gas or vapour, or with the aid of friction. But they act energetically through the surface of the true skin stripped of its cuticle, through the cellular texture under the skin, through the soft mucous membrane which lines the mouth, nose, ears, stomach, intestines, windpipe, and organs of generation, through the firm serous membranes which line the interior of the belly and chest, and also when introduced directly into the blood-vessels, more especially into the veins. They generally act with greatest energy when injected into the blood directly, or when introduced into the serous cavity of the chest or belly; but if they operate in very minute doses, their effects are scarcely less prompt when simply thrust into a fresh wound, or under the skin; and there is no way in which they exert their action with more swiftness and energy than when inhaled into the lungs, provided they assume the form of gas or vapour. For the most part their activity is greatest when applied to organs and textures where absorption is most prompt.

The action of poisons is greatly modified by an infinite variety of collateral circumstances, without a thorough knowledge of which toxicology cannot be well understood, either as a branch of physiological science, or in its practical bearings on medical practice, as well as medical jurisprudence. These modifying circumstances cannot be accurately laid down here; but the most important are the following:—Quantity or dose, chemical or mechanical form, the texture directly acted on, habit, and peculiarity of constitution, either natural or induced by disease. By all of these causes the effects of poisons may not merely be altered in degree, but likewise even modified in kind, or entirely neutralized. 1. Most substances which are poisonous in moderate doses are innocuous in small quantity; but some are amazingly energetic even in very minute quantities,—such as prussic acid or strychnia, the active principle of nux-vomica, either of which may prove fatal to a man in favourable circumstances in the dose of one grain; or still more, the poisonous secretion of venomous snakes, or the secretions of the human body in some diseased states, which will prove fatal in quantities inappreciably small if introduced into a wound. 2. As to mechanical form, poisons must be, or must become, either gaseous or liquid before they act. Mixture and dilution weaken their activity, though there are exceptions to this rule; and some, which are rather insoluble, such as arsenic, are rendered nearly inert when mixed with insoluble powders of great tenuity, such as charcoal, magnesia, and the like. 3. Chemical changes materially affect their actions; many corrosives becoming innocuous by neutralization, purely local irritants being thereby much enfeebled, and all of them being rendered more feeble, or even inert, if they are converted into substances insoluble in the secretions of the textures to which they are applied. Poisons that act through the blood on remote organs are little influenced by chemical changes, except in so far as their solubility is affected,—a very important general principle, which ought never to be overlooked in the search for antidotes. Arsenic, mercury, prussic acid, opium, and numberless other poisons, are almost equally active in all their chemical combinations, provided they continue soluble. 4. The effect of the texture acted on in modifying the influence of poisons has been already adverted to. As examples of this, it may be mentioned that prussic acid has little or no effect through the sound skin, nor snake-poison when swallowed; and that strychnia, the active principle of nux-vomica, has no effect through the skin, while one or two grains might prove fatal if swallowed, and a third of a grain would probably kill a man in a few minutes if injected in a state of solution into a wound, into the cavity of the chest, or into a vein. 5. Habit weakens the effects of many poisons, as in the familiar instances of opium and ardent spirits, of which ten or twenty times what is sufficient to prove fatal in ordinary circumstances may be taken with impunity by those who have long used them. Mineral poisons are less under the influence of this modifying circumstance than vegetable poisons; and of the latter those are most influenced which act chiefly upon the brain. It is very difficult to account for the varying effect of habit on the energy of vegetable poisons. Strychnia, for example, the active principle of nux-vomica, seems altogether excluded from the modifying effect of habit; while another principle, analogous in elementary composition and in chemical properties, morphia, the active principle of opium, may, through habit, be taken without injury in a dose fifteen times as great as what might in ordinary cases prove fatal. 6. Peculiarity of constitution commonly operates in rendering the body more than usually sensible to the action of poisons, as in the case of opium, mercury, and cantharides, medicinal doses of which act with poisonous violence on some. In a few instances original peculiarity deadens the activity of certain poisons; and this is observed still more remarkably during the constitutional state of certain diseases, such as hydrophobia, locked jaw, mania, delirium tremens, and excessive loss of blood. In some constitutions substances not injurious to mankind generally produce all the phenomena of poisoning. Thus there is scarcely any article of food or drink, except the great staple commodities, beef, mutton, and the simple kinds of bread, which are not at times observed to act poisonously on some people. But the most remarkable substances of the kind are red fish, shell-fish, mushrooms, bitter almonds in small quantity, and eggs.

Classification.

It has been stated that poisons are exceedingly numerous, but that they possess only a limited number of actions. As these actions consist of derangement of the functions of certain organs and textures of the body, it follows that the outward signs of these derangements must be circumscribed within certain bounds, and that many poisons must agree with one another in producing the same, or nearly the same, outward signs. This general fact constitutes the basis of the most approved classification. Formerly physiologists endeavoured to arrange poisons according to certain theoretical notions of their nature, or according to certain mysterious properties imputed to them; and subsequently most were content with distributing them in three classes, according to the kingdom of nature whence they happen to be derived. Every classification, however, should have some practical bearing; and as the most important objects in the present instance are the decision of the question of poisoning in a general sense, the discovery of the particular poison, and the treatment of its effects, these points ought to be invariably kept in view. With this understanding, the best classification is obviously that which is founded on the external signs of poisoning, that is, the grouping of the symptoms produced by each. Such is the basis of all the most esteemed modern arrangements.

The whole wonderful multiplicity of poisons, when thus viewed, may be considered as either exciting irritation in particular organs, or disordering the functions of the brain and spinal marrow, or as uniting both these properties. The first are called *irritants*, the second *narcotics*, the third narcotico-irritants, or more usually *narcotico-acrids*. The irritants comprise chiefly the free acids and free alkalis, with many of their compound salts, several earths with their salts, many compounds of the metals, acrid vegetables, and acrid animal substances. These all agree in producing, as their principal phenomenon, destruction or inflammation, sometimes of the part to which they are applied, such as the skin, mouth, throat, intestines, and so forth,—and at other times of organs at a distance from their place of application, such as the stomach, intestines, kidneys, bladder, lungs. And the symptoms they produce are those incidental to inflammation, generally, grouped, however, in so peculiar a manner, either in order, kind, or complexity, as in many instances to distinguish the cause which occasions them from any natural cause of inflammation. Many substances arranged among irritants produce effects which would also associate them with the class of narcotics; but still inflammation and irritation are their leading consequences. The narcotics comprise principally opium, prussic acid, the volatile oils of bitter almond, cherry-laurel, and other drupaceous plants; henbane, thorn-apple, deadly nightshade, and certain poisonous gases, such as carbonic acid, carbonic oxide, carburetted hydrogen, cyanogen, sulphuretted hydrogen. These agree in acting either upon the brain or upon the spinal marrow, or upon both these parts of the nervous system at once. The symptoms thus arising are stupor and coma, delirium, convulsions, paralysis, with a great variety of less important yet often very significant phenomena. When coma is the chief result, the brain is considered to be chiefly acted on; when convulsions or paralysis occur without stupor or coma, the spinal marrow must alone suffer; and where both sets of phenomena present themselves, it is probable that the whole nervous system partakes more or less of the injury. The narcotico-acrids comprehend hemlock and other deleterious plants of the family Umbelliferæ, black and white hellebore, meadow-saffron, fox-glove, ipecacuan, nux-vomica, *Cocculus indicus*, camphor, poisonous fungi, and all ethereal and alcoholic fluids, besides many others of less note, or not so familiar. It is difficult sometimes to separate the individuals of this class from the narcotics on the one hand and the irritants on the other. But for the most part they produce in different circumstances either narcotism or inflammation alone, or both conjunctly, and that either simultaneously or in succession.

Examples of their several kinds.

It may be well to illustrate these statements by a brief sketch of the effects of a few familiar or interesting species belonging to each class.

The purest examples of irritant poisons are the *strong mineral acids* and *alkalis*, namely, sulphuric, nitric, and muriatic acids, and potash and soda. These, when applied to the external parts of the body for a sufficient length of time, cause corrosion and consequent destruction; and life may be thus brought into imminent danger, either from the extent of the injury and the consequent sympathetic derangement of the vital functions, or from a variety of less direct or incidental disorders. Of such a course of things the public in this country had, some years ago, too many illustrations, resulting from the execrable crime of throwing sulphuric acid over the person. When swallowed, the strong mineral acids and alkalis sometimes act in a great measure on the throat and gullet, more frequently on the stomach and intestines. In the former case there is instant and horrible sense of burning in the mouth, throat, and neck, eructation of acid matter, often bloody, or mixed with dark masses, excessive tenderness of the injured parts, incapability of swallowing, difficult, husky breathing; and the sufferer may either die suffocated, or from the depressing sympathetic impression produced on the heart; or he may survive for a length of time, perishing, however, miserably in the end, from stricture of the gullet and starvation, or he may recover after the discharge of more or less of the lining membrane of the throat, and a tedious and precarious convalescence. Where the stomach and intestines are acted on by the acids or alkalis there is in general violent vomiting, often of blood, and, especially after swallowing anything, burning pain in the pit of the stomach, extending over the belly, with excessive tenderness and eventually swelling, frequently profuse purging and gripes, and extraordinary prostration of the pulse and of the strength; and the issue may be either recovery, more or less prompt, or far more generally death, at times from the sympathetic depression of the heart and general system, more rarely from gradual exhaustion, occasioned partly by constant irritation, partly by inanition, on account of extensive injury of the internal membrane of the stomach,—on which digestion probably in a great measure depends for its integrity. These phenomena are purely the results of local corrosion and irritation. No remote phenomena arise except exhaustion of the heart, from sympathy with the local injury; in particular, there is no disturbance of the function of the brain, spine, or nerves, except what arises simply from exhaustion of the circulation. The most remarkable of all the irritants for subtlety and variety of action conjoined is *arsenic*. It is not, however, an absolutely pure irritant; for, though irritation of a multifarious nature is its most prominent result, it also disturbs the functions of the nervous system. When applied for some time to the surface of the body, denuded of the scarf-skin, it kills the part to some depth; at least a portion is thrown off by the process of sloughing, showing either that the part had been killed, or that inflammation is produced of a kind which leads to its death. Both in this manner, and with much greater certainty if it is applied to a fresh wound, or introduced into any of the external openings of the body, or injected in solution into the cavity of the chest or belly, it excites irritation and inflammation, not merely where it touches, but likewise in various distant organs. The stomach and intestines suffer the most invariably, giving rise to violent vomiting, especially of all articles swallowed, burning pain in the bowels, tenderness, griping, purging, and excoriation of the anus. The kidneys, bladder, and organs of generation are also often affected, causing strangury, suppression of urine, pains in the loins, tenderness in the lower belly, &c. The lining membrane of the air-passages likewise frequently partakes in the injury, as is indicated by hoarseness, cough, difficult breathing, expectoration, and deep-seated pain in the chest. Not unfrequently the investing membrane of the nostrils and mouth presents signs of derangement, such as redness, aphthæ, and constant discharge. These symptoms are also generally attended with extraordinary depression of the action of the heart, which is the most frequent cause of death; and this sometimes forms the only prominent effect, the sufferer dying in a few hours, with scarcely any other symptom but mortal faintness. Recovery may take place even though the complicated effects which have been described may have been developed. But after these primary disorders have disappeared, there are important secondary risks to be encountered, such as dropsy, gradual emaciation from constant disturbance of digestion, and, above all, epilepsy, palsy, and other affections characteristic of an action upon the nervous system. Of the symptoms thus indicating a narcotic action, the most pointed and most remarkable are epileptic convulsions and local partial palsy. To these illustrations of the phenomena of internal poisoning produced by the irritants, it may be well to add a short sketch of the very striking effects produced by many of them as external poisons, when they have been introduced into the substance of the skin, or its subjacent cellular tissue, through a wound. Of poisons of the kind now alluded to, the most familiar are *snake-poison*, and the *fluids of the dead human body* after certain diseases or in some peculiar unknown state; but similar effects are also produced by many acrid vegetables. The affection produced is diffuse inflammation of the cellular tissue, so called because it diffuses itself rapidly along that texture, without any tendency to become circumscribed, as in ordinary inflammation similarly seated. It is attended with some puffy elevation and tenderness of the skin over the inflamed part, but not always with redness—with pain, not always acute, usually of that kind called burning pain—and with excessive depression of the action of the heart; and death may ensue, either in a few hours from the derangement of the function of the heart, or more slowly from extensive injury of the cellular tissue, which is apt to terminate in gangrene.

Of the phenomena produced by the narcotics, the purest and most familiar example is to be found in the effects of *opium*. This drug produces a great variety of interesting nervous phenomena when taken in small medicinal doses. When taken in a poisonous dose, it first occasions languor, giddiness, weakness, and drowsiness; afterwards deep sleep, attended in general with complete repose, soft, slow breathing, and highly contracted pupils; and then profound coma, or insensibility, which cannot be dispelled by any stimulants, and which usually proves fatal if it be allowed to be fully formed. In particular cases these symptoms are varied with delirium in the early stage, and convulsions in the advanced stage; but such deviations from the ordinary rule are rare. *Belladonna*, or *deadly nightshade*, is another narcotic which produces effects somewhat different. Its berries, which are sometimes eaten by mistake by children and other ignorant people, occasion in the first instance a singular state of very active delirium, in which the individual performs a series of incoherent and extravagant acts with much vivacity, or falls into the condition of somnambulism; and after some hours this is succeeded by a state of deep sopor or coma, as from opium, though more frequently intermingled with convulsions than in the case of that drug. Death is sometimes the result, and would be more frequent were it not that the precursory stage of active delirium often leads to the discovery of the offending cause, and its removal by fit treatment. *Prussic acid*, another pure narcotic, which is now almost as familiar as opium among poisons, rivals them all in subtlety and rapidity of action. Small animals, such as rabbits, have been killed with it in the brief space of four seconds. A single drop has killed a cat in half a minute, and one grain, or about four drops, has repeatedly proved fatal to man within three-quarters of an hour. These statements apply to the pure acid, which is seldom seen; but the common acid of the shops, which is used in medicine, is equally energetic in large doses; and so are the distilled waters and essential oils of the bitter almond, peach-kernels, cherry-laurel leaves, rowan-tree root, and apple-seeds, which all owe their poisonous qualities to the same cause. The effects produced by all these poisons are immediate: dreadful alarm, giddiness, and hurried breathing, speedily followed by convulsions, insensibility, one or two fits of deep convulsive respiration, and death. The *narcotic gases* act very much in the same manner with opium, as is well exemplified by the fumes of burning charcoal, and other forms of carbonic acid. When in a pure or concentrated state, carbonic acid extinguishes life immediately, in part by suffocation, on account of the exclusion of respirable air, and partly by its narcotic operation. But when breathed in a diluted state, as in an ill-ventilated mine, or in a confined chamber heated by charcoal, it induces giddiness, fulness of the features, ringing in the ears, gradually-increasing stupor, and at length profound insensibility, commonly attended with lividity of the face, glistening of the eyes, and occasional convulsions, which often prove fatal, and always, if not speedily relieved by fresh air and other suitable treatment.

The narcotico-acrids may be exemplified by a great variety of well-known and powerful poisons. *Hemlock*, which is believed to have been a familiar poison for more than 2000 years, but whose effects are generally misunderstood, ought scarcely to be arranged in this class, where it is commonly placed. Its irritant properties are very ill defined. But it is a powerful and very remarkable narcotic, and its active principle, named *conia*, is scarcely inferior to prussic acid in celerity of operation, or in the smallness of its dose. It seems to act by paralysing the muscles of voluntary motion and of respiration, without affecting the brain; and the symptoms are weakness of the limbs, gradually pervading the rest of the body, and terminating in loss of the power of motion, while at the same time the respiration, at first laborious, gradually becomes more and more circumscribed and slower, till at length it ceases, the heart all the while acting vigorously, and the sensation continuing unaffected. A better instance of a narcotico-acrid poison is *nux-vomica*, and its principle, *strychnia*. These are counterparts in action to hemlock and conia. They powerfully stimulate the spinal marrow, producing violent convulsions, like those which attend locked jaw or tetanus, and without impairing the sensibility. The first symptoms are restlessness, undefinable uneasiness, and alarm, speedily followed by fits of stiffness of the jaw and neck, and then by violent paroxysms of muscular contraction, in which the limbs and arms are extended, the features hideously distorted, and the head, body, and legs bent backward forcibly; and the third or fourth fit commonly proves fatal. Strychnia, the source of these dreadful effects, is on a par with prussic acid and conia in energy; for the third of a grain will kill a wild boar in ten minutes, and one grain properly administered would certainly kill a man in half that time. So far this genus of poisons acts like the narcotics; but in frequent instances, where the narcotic symptoms pass away, they are succeeded by the signs of inflammation in the stomach and intestines, namely, pain, vomiting, purging, and swelling of the belly, which affection, too, may prove fatal. Such irritant effects, however, are rare, perhaps because in the great majority of cases death is brought about in the early stage by the action on the nervous system. A better example still of a narcotico-acrid is *foxglove.* A most valuable and safe medicine in small doses, this plant nevertheless acts as a very dangerous poison in large doses; and it sometimes produces in the same case both deep coma with convulsions, and likewise profuse diarrhœa, with tormina and tenderness of the abdomen, while at the same time it occasions suppression of urine and extreme depression of the action of the heart. By far the most characteristic illustrations, however, of the narcotico-acrid poisons are to be found in the *deleterious fungi*, or poisonous mushrooms, as they are sometimes called. These differ from most other poisons in their effects being often put off (though to this rule exceptions exist) for several hours, apparently because time must be allowed for the digestion of substances on the whole difficult to digest. The effects are singularly various; for it has been often observed that, among a number of persons who have partaken of the same poisonous stew, some had only giddiness, confusion, delirium, stupor, coma, and convulsions; while others suffered only from vomiting and purging, distension of the belly, tenderness, and griping; and a third party were seized at first with the former class of symptoms, and on these passing partially off, were attacked severely with the latter.

Besides the irritant narcotic and narcotico-acrid poisons, some writers on the subject admit a fourth class, under the name of *morbid poisons*, comprising those poisonous secretions which are engendered in the body by disease, and possess the property of reproducing by contact or inoculation the same disease to which they owed their own production. The most important of these are hydrophobia, the venereal disease, small-pox, and cow-pox. Authors on toxicology, however, whether physiological or practical, have now generally agreed in discarding these from the toxicological system, and in arranging the phenomena of their action where they are more philosophically placed, namely, among natural diseases.

In a work like the present it is not easy to decide how much ought to be introduced of a subject so comprehensive as toxicology, or the science of poisons. The sketch given above will convey some idea of the objects of which it treats, more especially as a branch of physiology. Further details on the subject at large seem uncalled for. But there are two departments which may be enlarged on with some advantage, namely, the *evidence* of poisoning, and the *treatment* of the effects of poisons. Poisoning, both criminal and accidental, has become so common and so notorious in recent times, that there are probably few persons who have not turned their thoughts to these two branches of the subject; and it is desirable for many reasons that correct views should be entertained of them, even by unprofessional persons,—more correct views, at least, than what generally prevail.

Evidence.

Till a recent date, most erroneous notions were entertained, alike by the vulgar as by scientific men, of the evidence of poisoning. Proofs of the most unsubstantial kind were considered infallible tests of death by poison; and, under the authority of grievous professional error, we now know that courts of law must have sanctioned many a judicial murder. It is not uninteresting to trace these dogmas of antiquity, abandoned as they now are by the scientific, still obstinately adhered to by the unprofessional world as articles of popular belief, and leading, as of old, to constant blunders, which it is now the business and glory of the toxicologist to check, whilst it was formerly his fate to foster and give effect to them.

The evidence of poisoning cannot be thoroughly understood in all its bearings without a minute knowledge of the multifarious phenomena produced by all ordinary poisons; and, in judicial cases, it is in the end viewed commonly in reference to the supposed administration of a particular substance. It would be out of place to attempt embracing this wide field here. All which can be ventured on is, a view of the evidence of poisoning in a general sense, that is, without reference to any special poison,—a topic of great interest in relation to the first suspicions and earliest investigation of supposed cases of poisoning, whether criminal or accidental. The evidence of poisoning in this comprehensive sense is derived from symptoms, from appearances in the dead body, from experiments on animals, from certain moral circumstances, and from chemical analysis.

1. The *symptoms* are naturally the first particulars to attract attention and excite suspicion. They were once thought adequate to decide singly any question of poisoning. Now we know that natural diseases imitate so closely the phenomena of poisoning that the symptoms will rarely yield more than presumptive, and only in rare and very peculiar circumstances, absolute evidence. There is nothing in the kind of symptoms, taken generally, which will distinguish poisoning from certain natural diseases. The natural diseases, indeed, which imitate the effects of one great class of poisons,—namely, the irritants,—are on the whole rare; yet they are scarcely less a source of fallacy, at least in judicial cases, where certainty, or something like it, must be aimed at. But there are a number of collateral circumstances connected with the symptoms, which, if taken together, will often supply a very powerful criterion in supposed cases. Thus, in the instance of by far the greater number of poisons, and of almost all which are used for a homicidal or suicidal purpose, the symptoms begin soon after food, drink, or medicine has been taken, commonly within an hour, often much sooner; and in respect of not a few common poisons, such as the mineral acids, mineral alkalis, hartshorn, prussic acid, oxalic acid, they must commence immediately. In general, too, the symptoms begin suddenly, advance quickly, and prove speedily fatal. For the most part they are steady in their progress, exclusive of the influence of treatment. They are upon the whole uniform in their nature. And they appear in the great majority of cases abruptly during a state of good health. The consideration of these characters will not unfrequently enable the man of experience to pronounce that suspicions which have prevailed of poisoning are wholly unfounded; but taken singly, they will never justify, on the other hand, more than a presumption in favour of poisoning. It must at the same time be observed, that when these general characters are all applicable, and concur with a certain complicated grouping of the symptoms in particular cases, the presumption becomes very strong; and when other articles of general evidence are added, the proof may be all but complete, nay, absolutely so. Such is clearly the state of the case in not a few instances of poisoning with the mineral acids and alkalis, with arsenic, corrosive sublimate, nux-vomica, oxalic acid, prussic acid, alcoholic fluids. 2. The same confident reliance was long placed in the *appearances of the body after death* as in the symptoms, and with even less reason. The discovery of certain morbid appearances may prove poisoning to have been impossible; and yet even here an opinion should not be formed without reserve, because the discovery of the effects of natural disease in the body, even in an advanced stage, is no absolute proof of death from that disease. Poison, as in many authentic cases, may have been nevertheless administered, and have proved the real occasion of death. But there is never any-

thing in the appearances after death which will bear out a general charge of poisoning, as was once universally thought. It should be particularly known that the vulgar prejudice, which discovers poison wherever the skin becomes unusually livid after death, or wherever the body undergoes prompt decomposition, is utterly without support from scientific experience. Nay, in regard to the latter character, evidence has been proved in recent times to be deducible from the very opposite condition, or the unusual preservation of the body from decay, which is now well known to occur in many cases of poisoning with arsenic. There are certain morbid appearances in the dead body, especially upon the skin, and in the throat, gullet, and stomach, which will furnish the strongest presumption,—nay, according to good authorities, almost absolute proof,—of poisoning with certain substances; for example, the mineral acids; but the details cannot be entered upon here, because a full enumeration and much professional skill are required for appreciating precisely their import. 3. *Experiments on domestic animals*, made with suspected articles, were once supposed to furnish the best of all evidence; and this was probably the best evidence to be had in the days when chemistry and chemical analysis were all but unknown. Now, however, such experiments are not admitted, either by medical or legal authorities, to be of any weight, except under particular circumstances. They are admissible, and indeed clearly indispensable, for deciding questions in toxicological physiology which may arise during trials. They ought also to be allowed some weight when they have been observed accidentally, as, for example, when the remains of suspected articles have been devoured incidentally by domestic animals, especially by a number of them, and above all by the dog or cat, with the effect of producing in them symptoms and appearances after death similar to what were witnessed in the suspected case in the human subject. The objection drawn against such evidence, that the effects of many poisons on the brute creation are different from their effects on man, though fundamentally sound, has been allowed to operate far too sweepingly in modern times. The differences in respect to many common poisons are by no means so great as was thought not very long ago; and upon two animals, the dog and cat, the effects of most poisons are almost identical with those observed in man, due attention being paid to differences in dose, and to the singular facility with which these animals discharge poisons by powerful early vomiting. But the objection here stated may be allowed sufficient force to put an end to experiments made expressly on animals with suspected articles. There is, however, a more urgent objection to such experiments,—that they involve, for doubtful evidence, the consumption of materials from which decisive evidence may be obtained by other means; for if there is poison enough left to affect sensibly the lower animals, there is amply sufficient for detection by chemical analysis. Accordingly, express experiments with remains of suspected food, drink, or medicine, are now abandoned as a general rule by all good authorities in toxicology. In a limited class of cases, however, such experiments are still admissible, and ought to have great weight,—viz., when the poison is not of a kind to be satisfactorily detected by chemical characters, but is such as produces characteristic symptoms. 4. There are certain *moral circumstances* which may also be often taken into account in the evidence of poisoning in a general sense, when viewed as a scientific question, because they cannot be correctly appreciated except by a scientific man, and consequently they belong in some measure to the scientific or toxicological proof. The chief particulars are as follows:—It may be proved that poison has been purchased of a kind which may produce the symptoms observed. A suspicious article may be proved to have been administered, either from its taste, or from its having been recommended for properties either absurd in nature, or such as the pretended article is not thought even by unprofessional people to possess, or from a comparative analysis of the materials for making the suspected article, showing that something injurious must have been added at a particular time, and by a particular person. It may be proved that exacerbations of the symptoms have repeatedly occurred soon after articles were given in a suspicious manner. It may be proved that the person poisoned, or a second party under suspicion, exhibited by words or deeds an intention to administer poison, as by assigning impossible properties to what is administered, or by manifestly changing medicine which has been prescribed. A highly important circumstance is the simultaneous and similar illness of several individuals who have partaken of the same meal, coupled perhaps with the degree of their illnesses concurring with their respective shares, and probably also united with the escape of others of the same company who did not partake of the meal, or of particular dishes or liquors. Many other moral circumstances might be here alluded to, by which the question of poisoning in a general sense may be often materially cleared; but as they do not belong to the scientific view of the question, either directly or indirectly, they may be passed over. 5. The *chemical evidence* is justly considered the best of all the departments of proof; for it not only establishes poisoning in a general sense, but likewise points out the particular poison. There is no department of toxicology which has made such amazing progress in recent times as that of toxicological analysis. A century ago, the search for the remains of poison in suspected dishes, or in the dead body, was scarcely ever attempted, and, owing to the ignorance of the chemical properties of poisons, could not have been successful. Even no more than forty years ago, the method of analysis was in all cases crude and unsatisfactory, and for many poisons good processes continued unknown; so that it was no uncommon thing for charges of poisoning to break down, solely on account of the dubious quality of the chemical evidence. But at present the proof of poisoning is seldom defective in the chemical branch; the evidence of death by poison is usually complete; and how can it fail to be so in competent hands, when the analyst can detect in the most complex mixtures the minute quantity of a twentieth or fiftieth of a grain of the common poisons, and when many years of interment frequently cannot withdraw the crime of the poisoner from the keenness of the chemist's search? It has been proved by careful experiments that the mineral acids, arsenic, corrosive sublimate, blue vitriol, opium and its principle morphia, strychnia (the principle of nux-vomica), cantharides, and other less familiar substances, may be discovered in the body of animals poisoned with them, though buried for nine months; and instances have occurred of the detection of arsenic in man after interment for two, four, and even seven years. It does not absolutely follow that death has been occasioned by poison because poison is found within the body after death; for it may have been feloniously introduced afterwards, for the purpose of falsely imputing poison; or though poison has been swallowed, death may nevertheless have arisen either from natural disease, or some other kind of violence. Instances of such extraordinary occurrences are actually not uncommon; sufficiently so at least to require being kept always in view. The determination of them involves too refined an inquiry to be considered here. On the other hand, the non-discovery of poison after death is still further from being evidence that death was not occasioned by poison. For some poisons are still undiscoverable by any method of analysis; others are soon decomposed within the body after death, such as prussic acid; others are quickly absorbed from the stomach during life, so as to prove fatal without leaving any remains behind, as in many instances of poisoning with opium; others may be expelled by vomiting, and nevertheless have, in the first instance, occasioned injury enough to prove fatal, as sometimes happens in the case of arsenic, and very commonly in poisoning with mineral acids. It has, however, been made a subject of question, whether the evidence of poisoning can ever be considered as complete, so as to involve a conviction in a criminal case, unless poison be found either in the body or in the remains of a suspected article which has been swallowed. It appears absurd, however, to insist on the absolute necessity of such evidence. For were the poisoner to choose his means skilfully, and avoid over-doses, he would, on such principles, frequently escape. And the best scientific authorities, in the most recent times, seem inclined to allow that the general evidence from the various sources detailed above may be often so strong as to leave scarcely any scientific doubt of the occurrence of poisoning; and the conjunction of the circumstances of ordinary evidence may, in a legal sense, entirely remove what little doubt may have existed of a scientific nature. Accordingly there have been instances of condemnation, in this and other countries, where poison could not be discovered. It may be right to add, that it is most singular how effectually and how quickly poisons are sometimes removed beyond the reach of analysis by incidental causes, even those poisons which may be detected in other circumstances in extremely minute quantities, and where the methods of analysis are well understood. Prussic acid is seldom to be detected if life be prolonged for half an hour, while in the ordinary cases of death in a few minutes it may be discovered with ease. Arsenic, which in the great majority of cases adheres obstinately to the stomach, and may in consequence be detected there though life has been prolonged under frequent vomiting for two days and upwards, has been known to be removed from the stomach in the short space of five hours. It is of moment to observe, however, that, by reason of the improvements made in chemical analysis in recent times, some poisons, such as arsenic, though they may cease to be discoverable in the stomach, will be discovered in the blood, in the liver, and other fleshy organs, and also in the urine.

Treatment. The *treatment* of poisoning, like all other branches of toxicology, has, within a few years, been prodigiously improved. It may be said, indeed, to have been understood only within the last forty years. In ancient times the notions entertained of the treatment were not less crude than those formed of the nature and action of poisons. Among other errors, it was strangely supposed that certain counter-poisons existed, which not only possessed the property of curing the effects of all poisons indifferently, but which likewise, when taken for a length of time, had the faculty of impregnating the constitution, and rendering it proof against the influence of any poison. Princes and others often lived thus for years under the care of their physicians, or protected against their treachery, by being charged with conservative antidotes. After these notions were exploded, other erroneous practices came into vogue; and in particular it was believed to be established on the basis of observation, that certain antidotes, such as vinegar, milk, oils, and the like, which are really not amiss in some forms of poisoning, were equally efficacious in all. These illusions have been dispelled, even among professional people, only within very few years; and among the unprofessional they still have currency. The clearing away of the mists of error has been attended with the discovery of many real and most valuable remedies. The improvement which has thus taken place has been owing partly to the improvements made in chemistry; but in this way nothing could have been ultimately effected without the aid of physiological experiment, and more especially of experiments on animals; a method of inquiry, nevertheless, which it has been too much the practice of an ignorant or spurious humanity to decry.

The treatment of poisoning is directed to three objects,—the removal of the poison, the administration of an antidote, and the cure of the disorders which have been produced.

I. The first object in every instance is the prompt removal of what may remain of the poison. If it had been applied outwardly to a sore or wound, it must be carefully wiped or washed away. When introduced deep into or under the skin by a puncture, it is to be withdrawn by suction with the mouth, and, still better, with a cupping-glass, the efficacy of which is insured, as in the case of snake-poison, by a bandage being applied above the wound, so as to obstruct the return of blood from the veins to the heart, but without compressing the arteries. Another plan, which has been found effectual in the like circumstances, is simply to apply the bandage above the wound, and then to open a vein between the wound and bandage, so that the poison is drawn from the wound with the blood, and discharged outwardly from the orifice in the vein. Sometimes it is useful to make deep scarifications before applying the cupping-glass; yet in this way the bottom of the wound may be missed; and, on the whole, if incisions are to be made at all, it seems better to calculate the probable depth of the wound, and to remove a portion of the texture with the knife all around it. The bleeding which follows commonly effects the discharge of the remaining poison; but some afterwards add the use of an incandescent iron for cauterizing the whole adjacent parts. The removal of the poison, when taken internally, may be variously managed. But, first, care must be taken not to attempt its removal when nature may have already looked after this step in the treatment, as in the case of profuse, and frequent, and full vomiting. All that is necessary in such circumstances is to give occasional draughts of lukewarm water, or milk and water, to render vomiting easy, and to aid in washing out the stomach. When vomiting does not occur, or is not free, an emetic ought to be promptly given. Whatever is nearest should be first tried,—mustard, for example; but the most effectual is white vitriol, in the quantity of a scruple or half a drachm dissolved in a large wine-glassful of water, to be repeated in fifteen minutes if necessary. Where the symptoms indicate narcotic poisoning,—for instance, with opium,—it is essential to keep the person roused after giving the emetic, otherwise it will hardly act. Emetics, when they do operate, are greatly preferable to the stomach-pump, which has been of late currently substituted for them. The stomach-pump, however, is one of the most important additions which have been made to the healing art in modern times. In very many instances of narcotic poisoning emetics will not operate; and all such cases, till of late, inevitably perished when the quantity of poison was considerable. The stomach-pump insures the prompt removal of almost all poisons; so that when used in time recovery is next to certain, where formerly a large majority of cases proved fatal. 2. By all such means, however, the poison is often but partially removed. Some of it pervades the system; more of it impregnates the tissues with which it was in contact, and is ready for absorption; much of it often passes down into the intestines; occasionally it adheres with obstinacy to the inner membrane of the stomach, and cannot be dislodged either by emetics or by washing through means of the stomach-pump. The second object, then, is to administer an antidote. Antidotes have usually been conceived to be of two kinds. Some, by changing the chemical form of poisons, render them inert, and are called *chemical* antidotes. Others are thought to subdue the morbid action of poisons by exciting a counter-action, and are termed *constitutional* antidotes. In ancient times, and likewise until the recent improvements in toxicology, scarcely any other antidotes were known except what belonged to the constitutional class. But it is now thought that in correct language scarcely any such antidote exists. European physiologists are not acquainted with any decided constitutional antidote for any of the numberless multitude and variety of poisons now familiar to the scientific. It is very generally believed, however, that savages in all quarters of the world are in possession of remedies of this nature, more especially for the effects of snake-poison. Apparently authentic accounts have been published of a considerable variety of antidotes known to the natives in different parts of North and South America for the bite of venomous snakes. But none of these supposed antidotes have been found to stand the test of scientific investigation; natives who put trust in them have been seen to perish in the usual way; there is no difficulty in accounting for their apparent occasional success; and those who give faith to the marvels of travellers on the subject ought to consider how very extraordinary it would be if, in every part of the globe where there are savages, discoveries of this kind should be made in regard to their poisons, while, with all the advantages of science to aid them in the search, no civilized people have yet contrived to stumble on a similar discovery in relation to any of the innumerable poisons with which they have long been familiar. If constitutional antidotes are still much wanted, there is no want of excellent antidotes of the chemical class. Some of these act by neutralizing the chemical qualities on which the properties of the poison depend, others by simply rendering the poison insoluble. Thus sulphuric acid is rendered inert by magnesia, because it becomes thereby a neutral salt,—soluble, indeed, but no longer capable of corroding the animal textures, or of exciting violent irritation. In like manner, potash is rendered inert, or nearly so, by lemon-juice or vinegar, or, though less easily, by oil, because it is converted into neutral salts, which are feebly irritant and not at all corrosive. On the other hand, oxalic acid is rendered inert by magnesia, partly because its corrosive qualities are neutralized by chemical neutralization, but chiefly because these, in common with its not less formidable effects on the nervous system through absorption, are prevented by a substance resulting which is insoluble. So, too, arsenic becomes inert when brought thoroughly in contact with the hydrated peroxide of iron, because an insoluble compound is formed, the arseniate of iron. In using and searching for antidotes of the chemical kind, several important general rules should be attended to. For, first, where a poison is a pure local irritant, destitute of action through the blood or remote organs, it is usually sufficient that it be neutralized; because the resulting compound is commonly but a feeble irritant, although soluble. One condition, however, must be observed, namely, that the antidote shall be itself innocuous, otherwise harm may be done by the antidote before it comes in contact with the poison, or because it is given in excess. Thus the mineral acids are unfit antidotes for neutralizing the mineral alkalis, and the latter for neutralizing the former. But, secondly, when the poison is of a kind which acts on remote organs through the medium of absorption, it is not enough that it be chemically neutralized. For all such poisons act as such throughout their soluble compounds; their compounds act on the whole in proportion to their solubility; and those only are inert which are insoluble, and insoluble not merely in water, but likewise in the animal fluids of the stomach. Hence oxalic acid and arsenious acid (common arsenic) are not neutralized in their physiological actions by being neutralized with potash; prussic acid similarly treated remains as energetic as ever; and the powerful vegetable alkaloids,—morphia, strychnia, conia, and the like,—instead of becoming inert by neutralization with acids, are rendered positively more active, because they are made more soluble. In the case of every poison, then, it is advantageous, and in very many it is indispensable, that the chemical change effected shall be such as to impart to the compound insolubility; and care should be taken that this insolubility shall exist in regard to the natural juices of the stomach, which are commonly acidulous. But, thirdly, the antidotal tendency of such chemical remedies, even when of undoubted virtue, is often counteracted when the poison is a fine, rather insoluble, powder; for it adheres forcibly to the inner coat of the stomach, irritates it to throw out tough mucus, which covers the powder, and defends it against the approach of the neutralizing agent. Frequent instances of such a course of things occur in the case of poisoning with arsenic. 3. The last object of the treatment of poisoning is the cure of the disorders which the poison has produced. These disorders, since they are substantially natural diseases, must be treated as such. But there are certain circumstances which render them in some measure peculiar, and consequently modify the treatment. These are chiefly as follows:—Treatment will obviously be of little use for such disorders, until what remains of the poison be removed or rendered inert; and as this object is often unattainable, ultimate success is frequently beyond reach. Evacuation of the poison is in this point of view of primary importance, as well as for its own sake. In the case of poisoning with the irritants, the treatment is often exceedingly embarrassing, because it must be simultaneously directed towards two opposite ends,—the suppression of inflammation by evacuating, and consequently debilitating measures, and the removal of depression of the heart and general system by stimulating remedies. These two contrary and incompatible objects are often the cause why the best treatment proves inefficacious. The treatment of narcotic poisoning is somewhat differently circumstanced. The remains of the poison being removed, there is only the induced disorder to combat. These disorders are in the great majority of cases functional only,—that is, no structural injury has been occasioned. Hence, the offending cause having been withdrawn, there may be expected to prevail in the constitution a natural tendency to throw off the functional disorder,—a tendency towards recovery. Experience shows that such is actually the fact. If in narcotic poisoning the remains of the poison can be removed, and life can be preserved for a moderate length of time, success is highly probable in a great majority of cases. Thus very few die of poisoning with opium, and perhaps still fewer ought to die in skilful hands, who survive for eighteen hours; and few die of the effects of prussic acid who survive them for three-quarters of an hour. In narcotic poisoning, then, the treatment for subduing the disorders induced consists mainly in employing, in some instances, sedatives for subduing irritation of the nervous system, but much more commonly stimulants, for the purpose of keeping the person roused, and in applying various means for supporting artificial respiration when the natural breathing fails. Excellent methods for accomplishing the first object are now in familiar use,—such as loud talking, agitation of the body, injecting water into the ears, tickling the nostrils, dashing cold water over the head and shoulders, applying sinapisms to the calves, blistering the head with boiling water, and internally ammonia, ether, and spirits. But the best method of supporting artificial respiration has not yet been discovered; there are practical objections to all the methods yet devised; and it is only when these shall be perfected that the treatment of narcotic poisoning will be rendered substantially superior to what it is at present. It is not unlikely that galvanism will be found a material part of the most efficacious method,—applied, however, not continuously, as is often practised, but interruptedly, so as not to disturb the alternate contractions and relaxations of the respiratory muscles.

Actions o vegetable

In the preceding observations on the effects and treatment of poisoning, poisons have been regarded solely in their operation on the animal body. But they were defined at the outset as acting on living bodies generally; and upon vegetables their action is not less remarkable than upon animals. This branch of the subject has been hitherto little studied; but what is already known of it seems full of interest both in a physiological and in a practical point of view. It appears that in a general sense there is a close analogy between the actions exerted by poisons on both divisions of the living world. As there are two leading effects produced in animals, so are there two great classes of phenomena developed in vegetables,—those of irritation and those of narcotism, or at least of an action closely analogous. The apparent phenomena of both kinds are indeed much simpler in vegetable than in animal beings, partly because the organs and functions of the former are more simple than those of the latter, partly because physiologists have not yet ascertained with precision the special changes that are induced. Still, however, it is easy to trace in vegetables the leading effects produced by irritants and by narcotics respectively upon animals. The former occasion partial or general disorganization or death of the organs of plants to which they are directly applied, and the plant may eventually either recover or perish, according to the extent of the injury or the importance of the organ injured. The latter seem to act upon the vitality of the plant, without in general producing any marked change of a local nature, or such as may be referred to a direct impression, at least until the first signs of vital depression appear; and it is commonly observed that so soon as such signs of depression do make their appearance, however slight they may be, they quickly pervade the whole plant, which in consequence perishes irrevocably. The irritants appear to act topically, and from without inwards; the narcotics act more diffusively, and from within outwards, being probably first absorbed.

Poisons act upon vegetables, through whatever channel they are introduced, and to whatever organ they are applied, provided the texture be such as to admit of their passage to those parts which are more or less directly connected with life. The organs through which they act with greatest energy are the leaves and the roots. Liquid poisons act with most energy through the roots; gaseous poisons are probably most energetic when applied to the leaves. Partial action is sometimes produced by the topical application of a general or narcotic poison; thus arsenic introduced into the axilla of a leaf of the *Dipsacus fullonum* kills the whole superior part of the plant on the side corresponding with the leaf. Vegetable poisons are not less energetic than mineral poisons. Nay, however extraordinary it may appear, there seems no question that plants may be promptly killed by their own poisons,—that the poison produced by a particular species may kill that species as readily as it will others, if applied to the root so as to be absorbed into the nutritive juices. This singular phenomenon may depend on the poison being secreted and confined in particular receptacles in the ordinary state of the plant. But another and more intelligible explanation, in regard to certain poisons, may be drawn from the well-ascertained fact, that some vegetable poisons, and probably more of them than the physiologist may at present be inclined to admit, do not exist ready formed in the plants whence they are obtained, but are produced only when certain principles, existing naturally apart in distinct receptacles, are brought in contact by mechanical force or chemical manipulations. A remarkable instance in point is the essential oil of the bitter almond kernel or cherry-laurel leaf, which does not exist ready formed, otherwise it would be betrayed, like other essential oils, by its powerful odour, but is formed only when certain principles, named *amygdalin* and *emulsin*, are brought in contact with each other and with water.

No poisons are better fitted for illustrating the phenomena of poisoning in vegetables, or better deserve the attention of physiologists and practical men, than those which are gaseous in their nature. Most of them seem to act in excessively minute quantities and proportions. A tenth part of a cubic inch of muriatic acid gas, which is equivalent to the twenty-fifth part of a grain by weight, will in no long time destroy a small plant, although the gas be diluted with twenty thousand times its volume of air; and the devastating effects produced on surrounding vegetation by all manufactories where this acid is thrown abundantly into the atmosphere, as in the manufacture of black-ash and soda from sea-salt, abundantly show that far less proportions will prove equally deleterious when applied continuously. Sulphurous acid gas acts with nearly as great intensity. The effect of either of these poisons is simply to shrivel and wither the leaves and buds, like the action of frost in spring; and the plant will eventually recover if removed in time from the influence of the noxious agent, but, with the loss of its foliage. Other gases, such as sulphuretted hydrogen and cyanogen, produce no visible change until the leaves begin to bend and droop; after which the drooping quickly extends, till at length the whole plant becomes flaccid, so as to present exactly the same appearance as when deprived of moisture; and it perishes inevitably.

Some substances which are poisonous to animals are not poisonous to vegetables. The experiments which have been made on this subject are neither sufficiently extensive nor sufficiently exact to warrant any general deductions. A very remarkable instance is carbonic acid gas, a small proportion of which in the atmosphere will speedily extinguish animal life, but which is innocuous to vegetables in almost any proportion, nay, on the contrary, supplies them with aliment.

Uses.

Poisons are by no means without their uses in the economy of nature. It is, in the first place, not improbable that vegetable poisons serve some purpose in the economy of the plants which produce them. On this point we are still much in the dark, in consequence of the little advancement which has been hitherto made in vegetable physiology. But one purpose of the kind seems to be the perpetuation and extension of such plants by rendering them unfit for the food of herbivorous animals and frugivorous birds, which by instinct commonly avoid them. In the case of certain poisons of the animal kingdom, their purpose is obviously to preserve the animals which are endowed with them, by enabling them to destroy their prey and their enemies. Another important use to which poisons from every kingdom may be applied, is for the treatment of diseases. A very close connection subsists between medicinal and poisonous action. This is sufficiently shown perhaps by the undoubted fact, that, with very few exceptions, our best medicines are active poisons; and conversely, that there are few active poisons which have not been turned to account as useful medicines. Besides, in the greater number of instances, the two properties, medicinal virtue and poisonous influence, are plainly nothing else than manifestations of the same action, differing merely somewhat in degree, which is well exemplified by most purgatives and emetics, by opium, henbane, prussic acid, and other anodynes, and by counter-irritants, or substances employed for irritating the skin. In other instances, again, where the poisonous and medicinal actions are to appearance different and unconnected, the existence of some relationship between them seems to be pointed out by the activity of the substances as drugs being proportioned to their energy as poisons. Another purpose to which some poisons are applied is for the destruction of the lower animals for the use of man. In most parts of the world, where the primitive habits of mankind have not been materially modified by civilization, poisons of great energy are familiarly employed for the destruction of game, and in some countries also for killing beasts and birds of prey. In civilized countries they have hitherto been used chiefly for the more ignoble purpose of getting rid of vermin. But they are susceptible of far more important applications of the same nature, which, however, have been as yet entirely overlooked. (R. C.)

POISSON, Simon Denis. (See Dissertation Sixth.)

POITIERS, a town of France, capital of the department of Vienne, on the Clain, an affluent of the Vienne, 58 miles S.S.W. of Tours, and 78 N.E. of Rochelle. It stands on the rounded extremity of a chain of hills surrounded on all sides but the S.W. by narrow ravines, through which flow the Clain and its affluent the Boivre. The ancient walls, which skirted the banks of the rivers, are now almost entirely removed; and that part of them which crossed the high ground on the landward side is now a public walk, commanding a fine view of the rivers as they wind through their deep valleys. The town covers a very large space of ground, but it includes within its circuit gardens and fields, as well as houses, streets, and squares. The streets are generally steep, narrow, and crooked, lined with mean-looking houses, and the town in general has a dull and desolate appearance, were it not for the market-place, which is crowded and bustling. Many fine old buildings, especially churches, combine with the natural beauty of its position in giving Poitiers a very picturesque aspect. Some remains of a vast Roman amphitheatre still exist at Poitiers: the oval interior, now converted into a garden, and the tiers of seats for the spectators, replaced in some places by modern houses. Some of the vaults and corridors, and portions of the solid regular masonry, are still entire. Another very ancient building is now used as a museum, but was formerly a church, and seems to have been originally a baptistery. It is probably as old as the sixth or seventh century. The cathedral, said to have been founded by Henry II. of England, has two low and unequal towers, and is very elegant in the interior. The other churches are of much interest to the antiquary and the architect. On the highest part of the town stand the prefecture and court-house. Poitiers has an episcopal palace, a public library with 25,000 volumes and numerous MSS., a theatre, barracks, university academy, faculty of law, school of medicine, botanic garden, various scientific societies, &c. The manufactures comprise coarse woollen cloth, blankets, hosiery, lace, leather, playing-cards, vinegar, &c. Some trade is carried on in these articles, as well as in agricultural produce of various kinds. Poitiers is one of the most ancient towns in France. It existed, under the name of *Limonum*, in the time of the Romans, but it afterwards took the name of its inhabitants, the *Pictavi* or *Pictones*. After the fall of the Roman empire, it was possessed successively by the Vandals, Visigoths, and Franks. The last of these nations gained possession of it in consequence of the defeat of the Visigoths under Alaric by Clovis, in 507, not far from the town. In 732 Poitiers was the scene of another great battle, in which Charles Martel defeated the Saracens; and in 1356 the English, under the Black Prince, gained a victory over the French under John II., who was taken prisoner. It was the capital of the province of Poitou, which came into the possession of England by the marriage of Henry Plantagenet, afterwards Henry II., to Eleanor of Guienne in 1153; but it was taken from them by Philip II. in 1204. It was again in the possession of the English from 1360 to 1372. During the civil wars Poitiers, which was at first held by the Huguenots, was taken by the Catholics, and Coligny in vain attempted to recover it. Pop. (1856) 26,233.

POITOU, an ancient province of France, bounded on the N. by the provinces of Bretagne, Anjou, and Touraine; E. by those of Berri and Marche; S. by those of Angoumois, Saintonge, and Aunis; and W. by the Bay of Biscay. It was divided into Upper and Lower Poitou, and now forms the department of Vendée, the greater part of those of Vienne and Deux-Sèvres, and small portions of Haute-Vienne, Creuse, Charente, Charente-Inférieure, and Indre-et-Loire.

POKHURN, a town of India, in the Rajpoot state of Jodhpoor, 66 miles E. of Jessulmere, and 134 S.W. of Nagore. It is surrounded by a good stone wall; and the most conspicuous building is a temple, which stands in a deserted town quite close to the modern one. A considerable transit trade is carried on here, as the town stands on one of the great highways between Sinde and Eastern Rajpootana. Pop. about 15,000.

POKUR, a town of British India, in the district of Ajmere, N.W. Provinces, stands in a low swampy valley, on the S. shore of a lake, which is considered by the Brahmins the most sacred in India, 5 miles N.W. of Ajmere. Round the town stand many shrines and monuments of the princes and great men of India; and among these the most conspicuous is the shrine of Brahma. Flights of stone stairs descend from the temple to the sacred lake, to which, at full moon, great numbers of pilgrims resort. The town has many good houses, and beautiful gardens and vineyards. A fair is held here for horses, cattle, and other merchandise, at the full moon in October, when the concourse of pilgrims is much the greatest.

POL DE LEON, St, a town of France, in the department of Finistère, on the slope of a hill near the sea, 10 miles N.N.W. of Morlaix. It reminds the visitor of St Andrews in Scotland, being, like it, an ancient ecclesiastical but now almost deserted town, with grass-grown streets, and a very melancholy aspect. It contains two fine churches. The cathedral, built partly in the thirteenth and partly in the sixteenth century, has two beautiful towers surmounted with spires. The church of Kreizker, *i.e.*, middle of the town, is chiefly remarkable for its lofty spire of open work in granite, rising from a richly-ornamented square tower to the height of 404 feet above the ground, being second only to Strasburg among the spires of France. The manufacture of linen is carried on; and many of the inhabitants are employed in fishing. It has some trade through the suburb of Penpoull, on the sea-shore. Pop. 7059.

POLAND.

Poland, a name which once designated one of the most extensive and powerful of the kingdoms of Europe, but now indicates only a small integral portion of the Russian empire. In the fifteenth and sixteenth centuries its area is said to have exceeded 390,000 square miles, or more than that of France and Spain together; and even at the period of the first partition, in 1772, though by that time its limits had been much circumscribed, it had an area exceeding that of France, or about 283,000 square miles, and a population estimated at 13,000,000, probably more than that of the British Islands or of the Spanish peninsula at that period. It extended from Livonia and the Baltic on the N., to the Ukraine, Moldavia, and the Carpathians on the S.; from the Dwina and the Dnieper on the E., to Pomerania, Brandenburg, Bohemia, and Silesia on the W.

The Poles belong to the great family of the Slavonians, who, when the Goths and Vandals possessed themselves of Gaul, Spain, and Italy, left their ancient habitations E. of the Vistula, and gradually spread themselves to the S. and W. Though they frequently, like the other barbarians, disturbed the Roman Empire, yet they were generally peaceful in their character. They settled on the lands that other nations had relinquished, employing themselves as husbandmen and shepherds, in the domestic arts or in trade. They were characterized by their hospitality and honesty; and from their peaceful habits, were often deeply wronged by their more warlike neighbours. The name *Pole* came to be given to a portion of this race from a Slavonic word signifying "a plain," as the country which they inhabited was almost one uninterrupted level plain.

The first prince of Poland is said to have been Lech, who flourished in the middle of the sixth century. He founded the first city Gnesna, so naming it from *Gniazdo*, signifying "a nest,"—as an eagle's nest was found there; and hence the arms of Poland were a spread eagle. The descendants of Lech reigned in Poland for about 100 years, when the race being extinct, twelve palatines, or *woivodes*, were chosen, and the country divided into twelve parts. The people soon became dissatisfied with this government, and chose one of the twelve, Cracus, to be their sovereign. He reigned for about 30 years, and was much esteemed by the people. He founded Cracow, and removed the seat of his government from Gnesna to that city. He left three children, the eldest of whom, Cracus, succeeded him, but he was soon after murdered by his brother Lech. The latter did not long profit by his fratricide, for the crime having been discovered, he was deposed and banished by his subjects, and his sister Venda elected in his stead. She was celebrated for her beauty; and having refused the hand of a German prince named Rüdiger, he marched against her with a large army. According to some accounts she was defeated, and to save herself from falling into his hands she drowned herself in the Vistula; according to others, Rüdiger's forces having abandoned him without striking a blow, he killed himself in despair, and she was so much concerned at his death that she drowned herself. The race of Cracus being thus extinct, twelve woivodes were again appointed, but they soon fell out among themselves, and the country was invaded by the Hungarians and Moravians. One Prezimislas, a common soldier, having by stratagem overthrown the invaders, was raised to the dukedom under the title of Lesko I. After a long and prosperous reign, he died without leaving issue, and again the country was thrown into a state of anarchy. Several candidates appeared for the crown, and the Poles determined to elect him who should outstrip all the others in a horse-race. A certain nobleman, in order to secure the victory, caused the race-course to be strewn with iron spikes, and had the feet of his own horse protected by iron plates. The artifice took effect; but when he was about to be proclaimed victor, a peasant who had found out the deceit, opposed the ceremony, and exposed the fraud. The nobleman was immediately torn to pieces by the people, and the ducal authority conferred on the peasant. The new sovereign, Lesko II. conducted himself with great wisdom and moderation, and was distinguished both in war and peace. He is said to have at length fallen in a war with Charlemagne. He was succeeded by his son Lesko III., who inherited all his father's virtues. He concluded a peace with Charlemagne, and encouraged among his subjects the cultivation of the arts of peace. He was succeeded by his legitimate son Popiel I., but he left also a number of illegitimate sons, to whom he gave fiefs which were held of the crown. Popiel was a monster of cruelty and debauchery, and his son Popiel II. was, if possible, still worse. He found means to poison all his uncles (the illegitimate sons of Lesko III.), at an entertainment; but it is said that the vengeance of heaven soon overtook him, and he perished miserably with all his house. The nation now became a prey to civil discord; and at length a diet was assembled at Kruswick to choose a king. They could not, however, come to any agreement, and their presence soon brought on a famine in the town. A citizen named Piast liberally opened his stores for their use, and this act brought him the kingdom. He was proclaimed duke about 830, and his reign was long and peaceful. He engaged in no foreign wars, and was harassed with no domestic commotions. His son Ziemowitz, who succeeded him, was of a more warlike disposition than his father, and was the first to introduce regular discipline among the Polish troops. He was victorious in all his battles, and greatly enlarged his dominions. Lesko IV. succeeded him in 892. This prince was of a quiet and peaceful disposition, and contented himself with preserving what his father had left, without seeking to enlarge his dominions. He died in 913, and was succeeded by his son Ziemovistus. He, too, had a peaceful reign, which extended over 51 years, and was succeeded by his son Miecislas.

The above, with a sufficient admixture of the marvellous and fabulous, is the account given by the earlier Polish historians of the first period of their history. There can be little doubt, however, that their origin as a nation is fixed at too early a date; and Polish writers of our own time, Lelewel, Niemcewitz, Golembrowski, Zielinski, and others, are content to proclaim Miecislas I. as the true founder of the Polish monarchy.

Miecislas I.

Miecislas I., who attained the ducal authority in 964, was born blind, and remained so for seven years; but he afterwards obtained his sight without any assignable cause; and hence it was ascribed to a miracle. He became enamoured with Dombrowka, daughter of the Duke of Bohemia; but that lady refused to accept his suit unless he should suffer himself to be baptised. The ceremony took place on 5th March 965; and this is the date usually assigned for the introduction of Christianity into Poland, but it seems more probable that the Christian religion had reached the country before that time, though it had not come into public notice. The religion which the duke had thus been led to adopt he afterwards propagated with the greatest zeal. He founded the archbishoprics of Gnesna and Cracow, and appointed St Adelbert, who had been sent by the Pontiff to propagate Christianity in Poland, primate of the whole kingdom. He also enjoined that, when any part of the gospel was read, the hearers should half-draw their swords, in token of their readiness to defend its truths. **Boleslas I.** On his death in 999, he was succeeded by his son Boleslas I., surnamed the Brand, who was even more zealous than his father in extirpating the remains of paganism. He obtained the remains of St Adelbert, who had been murdered in Prussia, and deposited them with great pomp at Gnesna. Otho III., Emperor of Germany, having made a pilgrimage to the tomb of this saint, was so kindly entertained by Boleslas that in return he invested him with regal dignity; an act which was confirmed by the Pope. The elevation of Boleslas excited the envy of the Duke of Bohemia, who had vainly solicited that honour for himself; and his jealousy was further excited by the marriage of Miecislas Boleslas' son, with Rixa, the emperor's niece. He accordingly entered Poland at the head of a numerous army, and committed the most wanton and barbarous outrages. On the approach of the Polish army, however, he retreated with precipitation; and Boleslas, at the head of a formidable army, entered Bohemia. The Bohemians had not the courage to venture a battle; and after a siege of two years, Prague, the capital, was taken, and most of the other fortresses in the country speedily fell into the hands of the conqueror. He did not, however, rest satisfied with this, but followed up his advantages, resolved to obtain possession of the duke, which he at length did, and to satisfy his resentment, put out his eyes. From Bohemia he marched against Moravia, which submitted without striking a blow. He afterwards turned his attention to Russia, and found an excuse for invading that country in a civil war that was then raging between the children of the famous Vladimir. The chief competitors were Jarislas and Swiantopelk. Boleslas sided with the latter, and defeated Jarislas with great slaughter on the banks of the Bug. He took Kiow, the most celebrated and opulent city in that part of Europe, and became master of the greater part of Russia. He placed Swiantopelk on the throne, but he soon found in him a more dangerous enemy than his brother. This Russian prince had no sooner obtained the crown than he formed a conspiracy, which had for its object nothing less than the destruction of Boleslas and his whole army. The massacre was already begun, when Boleslas received intelligence of the scheme. He immediately mounted his horse, and having with the utmost haste assembled part of his army, fell upon the traitors with such fury that they were obliged to betake themselves to flight; and Boleslas got safe back to Poland. He now turned his arms against the Saxons, and extended his conquests to the Elbe. The inhabitants of the country to the north of Poland he also reduced to obedience. In 1018 the Russians, under Jarislas, attempted to invade Poland, but were defeated with great slaughter. By this victory Boleslas acquired a considerable tract of country, and the Russians were besides obliged to pay him a tribute. **Miecislas II.** This monarch died in 1025, and was succeeded by his son Miecislas, who possessed none of the great qualities of his father. In the beginning of his reign the Russians, Bohemians, and Moravians revolted; but as the spirit and discipline of the Polish troops still remained, Miecislas found no difficulty in reducing them to obedience, after which he devoted himself entirely to voluptuousness, and, at length worn out by his debauched course of life, he died in 1034. **Casimir I.** His queen Rixa was elected regent during the minority of his heir Casimir; but she proved tyrannical, and so partial to her countrymen the Germans, that a rebellion ensued, and she was forced to flee to Germany. Her son Casimir was also driven out of the kingdom, and a great many claimants started up for the vacant throne. This produced a civil war; and to add to their distress, the Bohemians and Russians invaded the kingdom in different places. At length it was resolved to recall the young prince, but as five years had already elapsed, no one knew where he was to be found. By interceding with his mother, however, they succeeded in obtaining the wished-for intelligence. He had at first retired into France, where he applied himself closely to study at the university of Paris; he afterwards went to Italy, where, after suffering great distress, he entered a monastery and assumed the religious habit; and subsequently he returned to France, where he obtained some preferment in the abbey of Cluny. It was here that he was found, but his vow presented an obstacle to his now accepting the crown. At length, however, the Pope consented to grant a dispensation of this tie, on condition that the nation should become subject to the tax called "Peter's pence;" that they should all shave their heads like monks, and wear white surplices at festivals. Casimir was welcomed with the greatest joy by all ranks of the people, and was crowned at Gnesna with more than usual solemnity. He proved himself worthy of the confidence of his people, and equal to the difficulties of his situation. He exerted his influence to repair the evils that had so long afflicted the country, restored the dominion of the laws, and subdued the banditti by which the country was infested. He secured peace with Russia by marrying the princess Mary, sister of the duke; and by his wise and peaceful reign he did more to strengthen and stablish the kingdom than could have been done by many victories.

Boleslas II.

He died after a reign of sixteen years, and was succeeded by his son Boleslas II., an enterprising and valiant prince, who soon rendered himself so famous that three unfortunate princes took refuge at his court, having been expelled from their dominions. These were Jaromir, brother of Wratislas, Duke of Bohemia; Bela, brother of the King of Hungary; and Zaslaf, Duke of Kiow, and cousin to the King of Poland. The Duke of Bohemia, dreading the consequences of his brother's escape, assembled an army, desolated Silesia, and laid waste with fire and sword the frontiers of Poland. Boleslas marched against him, and surprised him in the narrow passes of a forest. The duke being reduced to the greatest distress, proposed terms of peace, which, however, were rejected. In this extremity he resolved to attempt an escape during night, and, if discovered, to cut his way through the Polish army, or perish in the attempt. Ordering fires to be kindled in his camp, he drew off his forces with the utmost secrecy, and had advanced several leagues before Boleslas was aware of his retreat. The king pursued the fugitive, but in vain; and after ravaging the frontiers of Moravia, he returned to his own dominions. The next year he entered Bohemia with a numerous army, and the duke, unwilling to encounter so formidable an adversary, submitted to terms of peace, which contained conditions in favour of Jaromir. He now turned his attention towards Hungary, and entered that kingdom at the head of a numerous army. The Hungarian king, supported by a large body of Bohemians, prepared to meet him; and a battle was at length fought, in the heat of which the Hungarian portion of the troops went over to the enemy, and the auxiliaries were killed almost to a man. The king himself was taken prisoner, and treated with such cruelty that he died soon after of a broken heart; and Bela was placed on the throne without further opposition. He next, at the head of a numerous and well-disciplined army, marched into Russia, ravaged the territories composing two palatinates, reduced the strong city of Wolyn, and transported the booty to Poland. The campaign was finished by a battle, which proved so bloody that, though Boleslas was victorious, his army was so weakened that he could not pursue his conquests. In the winter he made numerous levies, and returning in the spring to Kiow, reduced it by famine. On this occasion he treated the inhabitants with kindness, commending their valour, and distributing provisions amongst them with the utmost liberality. This clemency procured the highest honour to the King of

Poland; but his stay here was productive of a great disaster. Kiow being the most dissolute as well as the richest city in the north, the king and his soldiers gave themselves up to the pleasures of the place. Boleslas himself affected all the state of an eastern monarch, and contracted an inclination for the grossest debaucheries. The Hungarian and Russian wars having continued for seven years, during that time the king had never been at home, excepting for the short space of three months; and the Polish women, exasperated at hearing that their husbands had neglected them, raised their slaves to the beds of their masters, in order to be revenged for the infidelity of their husbands. This was so general that history has only handed down the name of one lady as remaining faithful to her lord—Margaret, wife of Count Nicolas de Zembosin. The soldiers hearing of this, blamed the king for their dishonour, and resolved to return home, in order to take vengeance upon their wives and their paramours. A dreadful kind of civil war now ensued. The women, knowing that they had no mercy to expect from their husbands, persuaded their paramours to take arms in their defence, and they themselves fought by the side of their gallants with the utmost fury, seeking out their husbands in the heat of battle, in order to secure themselves from all danger of punishment. They were, however, on the point of being subdued, when Boleslas, who had been left almost alone in the heart of Russia, arrived with the few remaining Poles, assisted by an army of Russians, with whom he resolved to take equal vengeance on the women, their gallants, and his own soldiers who had deserted him. This produced a carnage more dreadful than ever. The soldiers united with their former wives and their gallants against the common enemy, and fought against Boleslas and the Russians with the fury of lions. At last, however, the fortune of the king prevailed; the rebels were totally subdued; and the few who escaped the sword were tortured to death or perished in prison.

To add to the calamities of this unhappy kingdom, the schisms which for some time had prevailed in the Church of Rome found their way also into Poland; and the matter at length came to be a contention for wealth and power between the king and clergy. Bloodshed followed. The Bishop of Cracow was, like another Thomas à Becket, massacred in the cathedral whilst he was performing the duties of his office. Pope Gregory VII. thundered out anathemas against the king, released his subjects from their allegiance, and laid the kingdom under a general interdict. The whole kingdom became a scene of confusion, and the king fled with his son Miecislas, and took refuge in Hungary. Authors differ respecting the manner of his death, but the generally received account is that, being driven from place to place by the persecutions of the clergy, he was at last obliged to become a cook in a monastery at Carinthia, where in this mean occupation he ended his days.

Uladislas I.

The kingdom continued under a severe interdict, which could be removed only by the most abject concessions; but at length the Pontiff consented that the brother of the deceased monarch should be raised to the sovereignty, but only with the title of Duke. This prince, named Uladislas, being of a meek disposition, with little ambition, accepted the terms offered, and sent an embassy to Rome, earnestly entreating the removal of the interdict. The request was granted; but all his endeavours to recover the regal dignity proved fruitless, the Pope having, in conjunction with the Emperor of Germany, conferred that honour on the Duke of Bohemia. Russia availed itself of the recent disturbances to throw off the yoke; and this revolt drew after it that of Prussia, Pomerania, and several other provinces. The smaller provinces were soon reduced; but the duke had no sooner returned to Poland than they again rebelled. He marched against them with a considerable army; but was entirely defeated, and obliged to return. Next year, however, having led against them a more numerous army than before, he compelled them to submit and deliver up the ringleaders of the revolt. But no sooner were the Pomeranians reduced than civil dissensions took place. Sbigniew, his son by a concubine, was placed by the discontented nobility at the head of an army to subvert his father's government and dispute the title of Boleslas, his legitimate son, to the succession. Sbigniew was at length defeated and taken captive, but was afterwards pardoned and received into favour.

Boleslas III.

Uladislas died in 1102, in the fifty-ninth year of his age, and was succeeded by his son Boleslas III.; but a portion of his dominions was assigned to his brother Sbigniew. The latter, being dissatisfied with his share, stirred up the Bohemians, Saxons, and Moravians against his brother, and made such formidable preparations as threatened the conquest of all Poland. Boleslas, unable to oppose such a formidable force, had recourse to the Russians and Hungarians, who readily embraced his cause. At length Sbigniew was defeated, and might have easily been obliged to surrender at discretion, had not Boleslas generously left him in quiet possession of the duchy of Mazovia. Sbigniew, however, subsequently entered into other conspiracies, and was at length banished from the kingdom.

Boleslas was scarcely freed from the intrigues of his brother when he found himself in danger from the ambition of the Emperor Henry V. The emperor had attacked the King of Hungary, with whom Boleslas was in close alliance. The King of Poland determined to assist his friend, and therefore made a powerful diversion in Bohemia, where he repeatedly defeated the imperialists. The emperor then collecting all his forces, ravaged Silesia, and even entered Poland, where he laid siege to the strong town of Lubusz; but he was at last obliged to abandon the enterprise, after having sustained severe loss. Henry, in no degree discouraged, penetrated still farther into Poland, and was laying waste all before him, when the superior skill of Boleslas compelled him to retire. Enraged at this disappointment, Henry laid siege to Glogau, and after a spirited defence, the inhabitants were on the point of surrendering when Boleslas arrived and attacked the emperor with such vigour that he obliged him to retreat with disgrace into his own country. This soon brought on a peace, which was confirmed by a marriage between Boleslas and the emperor's sister. About 1135 he was brought into a war with Russia. He had conferred the government of Wislica, a strong town on the Nida, to a Hungarian who had insinuated himself into his affections; but the traitor delivered up the place to the Russians. Boleslas, incensed, immediately entered into a war with Russia. Having been implored for assistance by the inhabitants of Halitz, Boleslas marched to their relief with a choice body of troops; but as he was preparing to enter the town he was attacked by the Russian army, and, after a most violent conflict, entirely defeated. The unfortunate prince was so much afflicted by this reverse, that in a short time he died, after having reigned thirty-six years.

Uladislas II.

By his will he divided his dominions equally amongst his four grown-up sons. Uladislas, the eldest, had the provinces of Cracow, Sieradz, Lencsysa, Silesia, and Pomerania. Boleslas, the second son, had for his share the palatinates of Culm and Kujavia, with the duchy of Mazovia. The palatinates of Kalszh and Posen fell to Miecislas, the third son; and to Henry, who was the fourth, were assigned those of Lublin and Sandomir. No provision was, however made for Casimir, the youngest child, then an infant in the cradle. The eldest son had a certain superiority over his brothers.

The harmony of the princes was soon disturbed by the ambition of Christina, the wife of Uladislas, who formed a scheme to get possession of all Poland. Having obtained

Boleslas IV.

her husband's concurrence, she assembled the states of Poland, and made a long speech, showing the dangers which might arise from a partition of the ducal dominions amongst so many; and concluded with attempting to show the necessity of revoking the ratification of the late duke's will, in order to insure the tranquillity of the republic. At length all the nobility were gained over or intimidated by Uladislas, who then drove Boleslas from his territories, and next marching against Henry, dispossessed him also, forcing both to take refuge with Miecislas in Posnania, where all the three brothers were besieged. Thus driven to despair, the brothers sallied out, attacked the duke's army, and obtained a complete victory, taking possession of all his baggage and effects. They next laid siege to Cracow, which surrendered; and Uladislas retired into Germany to solicit assistance. Boleslas was raised to the supreme authority, and the new duke began his administration with an act of generosity towards his brother Uladislas, on whom he conferred the duchy of Silesia, which was thus separated from, and has never since been re-annexed to Poland. Uladislas, not content with this, found means to persuade the Emperor Conrad to invade Poland. Boleslas, however, so harassed and fatigued his army that he was soon obliged to return to his own country; and for some years Poland enjoyed profound tranquillity. The Emperor Frederic Barbarossa was next persuaded by Uladislas and his wife to invade Poland. The number of the Imperialists was so great that Boleslas and his brothers did not think proper to oppose them in the open field. They divided their forces, and laid waste the country before the enemy, burning all the towns and cities which were in no condition to stand a siege. Thus the emperor was at last reduced to such a situation that he was glad to come to terms, and the treaty was confirmed by a marriage between Adelaide, niece of the emperor, and Miecislas, Duke of Posen.

Boleslas subsequently attempted the conquest of Prussia, but his army having fallen into ambush, was almost entirely cut off; Duke Henry was killed, and Boleslas and Miecislas escaped with great difficulty. After this, Boleslas applied himself to promote the happiness of his subjects, and continued thus occupied until the period of his death, which happened in the year 1173.

Miecislas III.

On the death of Boleslas, the states raised his brother Miecislas to the ducal throne. But the moment that Miecislas ceased to be a subject he became a tyrant, and the slave of almost every vice; so that in a short time he was deposed, and his brother Casimir elected in his stead.

Casimir II.

Casimir, a prince remarkable for his justice and benevolence, set himself about securing peace and establishing tranquillity in all parts of his dominions. He redressed grievances, suppressed exorbitant imposts, and assembled a general diet, in which it was proposed to rescue the peasants from the tyranny of the nobility. The nobles, influenced by the example of their sovereign, immediately granted all that he required; and, to give still greater weight to this decision, the acts of the diet were transmitted to Rome, and formally confirmed by the Pope. But though the nobility in general consented to the partial retrenchment or limitation of their power, it occasioned discontent amongst some, who for this reason immediately became the partisans of the deposed Miecislas. That unfortunate prince was now reduced to such indigence, that his brother Casimir, affected by the accounts he had received, tried every method to relieve him, and even connived at the arts that were practised by some discontented noblemen to restore him. But this generous and amiable conduct was repaid by the grossest ingratitude. Miecislas used every art to wrest from his brother the whole of his dominions, and actually conquered the provinces of Mazovia and Cujavia; but of these he was soon dispossessed, and only some places in Lower Poland were left him. The last action of this amiable prince was the conquest of Russia, which he effected rather by the reputation of his wisdom and generosity than by the force of his arms. The people of that country voluntarily submitted to a prince so famed for his benevolence, justice, and humanity. Soon after his return he died at Cracow, lamented as the best prince that had ever filled the throne of Poland.

Lesko V.

Uladislas III.

Casimir left two sons very young, the elder of whom, named Lesko, was nominated his successor. Miecislas embraced the opportunity of renewing his attempts upon the throne, and formed an alliance with the Dukes of Oppeln, Pomerania, and Breslau. Having raised all the men in Lower Poland fit to bear arms, he took the road to Cracow with a numerous army. On the banks of the river Mozgarva a sanguinary conflict ensued; but both sides were so much weakened that they were forced to retire for some time, in order to repair their losses. Miecislas now had recourse to artifice rather than force; and having attempted in vain to corrupt the guardians of Lesko, he entered into a compact with the Princess Helen, his mother. Representing in the strongest manner the miseries which would ensue from war, he stipulated to adopt her sons Lesko and Conrad as his own; to surrender the province of Cujavia for their present support; and to declare them heirs to all his dominions. The principal nobility opposed this accommodation; but it was accepted by the duchess in spite of all their remonstrances; and Miecislas was once more put in possession of the capital, after having taken a solemn oath to execute punctually every article of the treaty. The princess was not long in perceiving that she had been duped, and having formed a strong party, she excited a general insurrection against the duke. Miecislas was expelled from Cracow, and on the point of being reduced to his former indigence, when he found means to foment a quarrel between the duchess and the palatine of Cracow, and thus once more turned the scale in his favour. He regained possession of Cracow, but did not long enjoy his prosperity, for he fell a victim to intemperance in 1203. He was succeeded by his eldest son, Uladislas III., a prince noble and generous as his father had been base and treacherous. Knowing that the crown rightfully belonged to his cousin Lesko, he was with difficulty induced to accept of it, and at length willingly resigned it to him, after a short reign of three years.

Lesko V. restored.

Tartar invasion.

During the government of Lesko the Tartars made an irruption into that country, and everywhere committed the most cruel ravages. At last they came to an engagement with the Poles, and obtained a complete victory. This incursion, however, terminated as precipitately as it had commenced; but the devastations they had committed produced a famine, which was soon followed by a plague that depopulated one of the most populous countries of the north. In this unhappy situation of affairs, death ended the misfortunes of Lesko, who was assassinated by his own subjects. A civil war followed his death; and the history of Poland is for some time so confused that it is difficult to say who was his successor. During this unfortunate state of the country, the Tartars made a second irruption, laid all waste before them, and were advancing towards the capital, when they were attacked and defeated with great slaughter by the palatine of Cracow, with only a handful of men. Next year, however, they returned, and committed barbarities such as can scarcely be imagined. Whole provinces were ravaged, and every one of the inhabitants massacred. They were returning, laden with spoil, when the palatine fell upon them a second time, but after a most obstinate engagement, he was defeated, and all Poland was thus laid open to the ravages of the barbarians. The nobility fled into Hungary, and the peasants sought an asylum amongst rocks and impenetrable forests. Cracow was taken, pillaged, and burned; and the barbarians, penetrating into Silesia and Moravia, desolated these countries, destroying Breslau and other cities.

Boleslas V. Poland was in this dreadful situation when Boleslas, surnamed the Chaste, obtained the sovereignty. But this, so far from putting an end to the troubles, only superadded a civil war to the other calamities with which the country was afflicted. Boleslas was opposed by his uncle Conrad, the brother of Lesko, who having assembled a powerful army, gained possession of Cracow, and assumed the title of Duke of Poland. His avarice and pride, however, offended equally the nobility and the peasants; and they unanimously invited Boleslas, who had fled into Hungary, to return home and head the insurrection which now broke out in every quarter. On his arrival, he was joyfully received in the capital. But Conrad still headed a powerful party; and it is reported that on this occasion the knights of the Teutonic order were first called into Poland, to dispute the pretensions of Boleslas. All endeavours of Conrad, however, proved unsuccessful. He was defeated in two pitched battles, and forced to live in a private situation; though he never ceased to harass his nephew, and make fresh attempts to recover the crown. Of the reign of Boleslas, however, we have little information, except that he made a vow of perpetual continency, and imposed the same on his wife; that he founded nearly forty monasteries; and that, after a long reign, he died in 1279, having previously adopted Lesko, Duke of Cujavia, and procured a confirmation of his choice by the free election of the people.

Lesko VI. The reign of this last prince was one continued scene of foreign and domestic trouble. On his accession, he was attacked by the united forces of Russia and Lithuania, assisted by the Tartars; but he had the good fortune to defeat the confederate barbarians in a pitched battle. This was followed by civil dissensions, which rose to such a degree that he was obliged to fly to Hungary, the common resource of distressed Polish princes. The inhabitants of Cracow alone remained firm in their duty, and withstood a tedious siege, until they were at last relieved by Lesko at the head of a Hungarian army, who defeated the rebels, and regained the government. But scarcely had he reascended the throne when the united forces of the Russians, Tartars, and Lithuanians made a second irruption into Poland, and desolated the country with the most savage barbarity. Their forces were now rendered more terrible than ever by their having along with them a vast number of large dogs trained to join in their attacks. With an army much inferior, however, Lesko obtained a complete victory, the Poles being animated by all the fury of despair. Soon after this, Lesko died, with the reputation of a wise, warlike, but on the whole an unfortunate prince.

Prezemislas. **Uladislas V.**

As this prince died without issue, a civil war again ensued; and the affairs of the state continued in a very declining condition till 1296, when Prezemislas was crowned king by the Archbishop of Gnesna, a title which had been forfeited for more than 200 years. He did not enjoy this title for more than seven months, having been murdered, it is said, by some Brandenburg emissaries. A series of dissensions again succeeded till the year 1305, when Uladislas Lokietek, who had seized the throne in 1300, and afterwards been driven out, was restored. The first transaction of his reign was a war with the Teutonic knights, who, during the recent disturbances, had usurped the greater part of Pomerania. They had been settled in the territory of Culm by Conrad, Duke of Mazovia, but soon extended their dominion over the neighbouring provinces, and had even obtained possession of the city of Dantzic, where they massacred a number of Pomeranian gentlemen in cold blood. The knights were commanded by the sovereign Pontiff to renounce their conquests; but they set at nought all his thunders, and even suffered themselves to be excommunicated rather than part with their acquisitions. Uladislas entered the territory of Culm, which he laid waste with fire and sword; and although opposed by the joint forces of the Marquis of Brandenburg, the knights, and the Duke of Mazovia, he obtained a complete victory, after a desperate and bloody engagement. Without following up the blow, however, he returned to Poland, where he recruited his army; and being reinforced by a body of auxiliaries from Hungary and Lithuania, he a second time ravaged all the dominions of the Teutonic knights. A treaty was concluded under the mediation of the kings of Hungary and Bohemia. But in a few months the knights not only refused to evacuate Pomerania, as had been stipulated in the treaty, but even endeavoured to extend their usurpations, and for this purpose assembled a very considerable army. Uladislas, enraged at their treachery, once more took the field, and gave them battle with such success that 4000 knights were left dead on the ground, and 30,000 auxiliaries killed or taken prisoners. Though the king had it in his power to destroy the whole order, he satisfied himself with obtaining the territories which had occasioned the war, after which he spent the remainder of his life in tranquillity and peace.

Casimir III. Uladislas was succeeded by his son Casimir III. surnamed the Great. Having in a single campaign subdued the province called Black Russia, he turned his arms against Mazovia, which he overran with great rapidity, and annexed as a province to the crown. He then applied himself to domestic affairs, and was the first who introduced a written code of laws into Poland. He was a most impartial judge, a rigid observer of justice, and the most submissive to the laws of any potentate mentioned in the history of Europe. He was a great patron of industry as well as an eminent legislator, and through his encouragement numbers flocked into his kingdom from various parts of Germany. He fortified many of his chief towns, which he also embellished; whilst colleges, hospitals, churches, and other public buildings, attested alike his genius, his magnificence, and his patriotism. His reign is considered as the golden age of Poland.

Louis. Casimir was succeeded in 1370 by his nephew Louis, King of Hungary; but as the Poles looked upon him as a foreign prince, they were not happy under his administration. He left Poland almost as soon as he was crowned, leaving the government in the hands of his mother Elizabeth. But at that time the state of Poland was too disturbed to be governed by a woman. The country was overrun with gangs of robbers, who committed the most horrid cruelties; the kingdom was likewise invaded by the Lithuanians, the province of Black Russia had revolted, and the land was universally filled with dissension. The Poles, displeased to see their towns occupied by Hungarian garrisons, sent a message to the king, informing him that they thought he had been sufficiently honoured in being elected king of Poland himself, without suffering the kingdom to be governed by a woman and his Hungarian subjects. Upon this, Louis raised a numerous army, intending to subdue the refractory spirit of his subjects. His first operations were directed against the Russians, whom he defeated, and again reduced to subjection. He then turned his arms against the Lithuanians, expelled them from the kingdom, and re-established public tranquillity. He died after a reign of twelve years, and his daughter Hedwig was proclaimed queen.

Uladislas. This princess married Jagellon, Duke of Lithuania, who was converted to Christianity, and baptized by the name of Uladislas. By this marriage, the duchy of Lithuania, as well as the vast provinces of Samogitia and Black Russia, were annexed to the crown of Poland. Such a formidable accession of power excited the jealousy of the Teutonic knights, and they assembled a large army, and suddenly invaded his territory. Uladislas raised a strong force with the utmost celerity, which he committed to the care of his brother Skirgello. The Teutonic knights were defeated, and obliged to abandon all their conquests.

After some years of peace, a long series of wars broke out between Poland and Prussia. The knights having now got possession of Samogitia, Mazovia, Culm, Silesia, and Pomerania, Uladislas resolved to punish them before they became too powerful; and with this view he assembled an army composed of several different nations. He then penetrated into Prussia; took several towns; and was advancing to Marienburg, the capital of Pomerania, when he was met by the army of the Prussian knights, who determined to hazard a battle. When the engagement began, the Poles were deserted by all their auxiliaries, and obliged to stand the brunt of the battle. But the courage and conduct of their king so animated them that, after a most desperate struggle, they obtained a complete victory; nearly 40,000 of the enemy being killed on the field, and 30,000 taken prisoners. Uladislas did not improve his victory, and a peace was concluded upon easier terms than his adversaries had any reason to hope for.

Uladislas VI.

Uladislas V. died in 1434, and was succeeded by his son Uladislas VI., at that time only nine years of age. He had scarcely ascended the throne, when the kingdom was invaded by the Tartars, who defeated the general of the Polish forces; and, committing everywhere dreadful ravages, returned to their own country loaded with booty. A few years afterwards the nation was involved in a war with Amurath, the sultan, who threatened to break into Hungary. But before the young king took the field, a strong body of auxiliaries was despatched under John Hunniades, woivode of Transylvania, to oppose the Turks, and likewise to support the election of Uladislas to the crown of Hungary. This detachment surprised the Turkish army near the river Morava, and defeated Amurath with the loss of 30,000 men; after which Hunniades retook all the places which had been conquered by Amurath, the sultan was forced to sue for peace, and Uladislas was raised without opposition to the crown of Hungary. A treaty was concluded, by which the Turks promised to relinquish their designs upon Hungary, and to give up all their conquests in Bosnia and Servia. This treaty was sealed by mutual oaths; but Uladislas broke it at the persuasion of the Pope's legate, who insisted that now was the time for humbling the power of the infidels, and produced a special commission from the Pope, absolving the king from the oath he had taken at the late treaty. The result of this perfidy was, that Uladislas was entirely defeated and killed at Varna, and the greater part of his army cut in pieces.

Casimir IV.

Uladislas VI. was succeeded by Casimir IV., in whose reign the Teutonic knights were subdued, and obliged to yield up the territories of Culm, Michlow, and the duchy of Pomerania, together with the towns of Elbing, Marienburg, Talkmith, Schut, and Christburg, to the crown of Poland. On the other hand, the king restored to them all the other conquests he had made in Prussia; granted a seat in the Polish senate to the grand-master; and endowed him with other privileges, on condition that, six months after his accession, he should do homage for Prussia, and take an oath of fidelity to the king and republic.

About this time the crown of Bohemia having become vacant, the barons were induced to bestow the crown upon Uladislas, eldest son of Casimir, in opposition to the intrigues of the King of Hungary. Not satisfied with this acquisition, Uladislas took advantage of the dissensions in Hungary, in order to unite that crown to his own, and thereby he greatly augmented his power. Casimir died in 1492. In the reign of this prince, the deputies of the provinces first appeared at the diet, and assumed to themselves the legislative power; all laws before that time having been framed by the king in conjunction with the senate.

John Albert. Alexand Sigismur I.

During the succeeding reigns of John Albert and Alexander, sons of the last monarch, the affairs of Poland fell into decline, the kingdom being harassed by continual wars with the Turks and Tartars. But they were retrieved by Sigismund I., who ascended the throne in 1507. This monarch, having reformed some internal abuses, set about rendering the kingdom as formidable as it had formerly been. He first quelled an insurrection which broke out in Lithuania; after which he drove the Wallachians and Moldavians out of Black Russia, and defeated the Russians in a pitched battle, with the loss of 30,000 men.

After this victory, the king turned his arms against the Teutonic knights, who had elected the Marquis of Brandenburg as their grand-master; whilst this prince not only refused to acknowledge the sovereignty of the crown of Poland, but even invaded the Polish territories. Sigismund marched against him, and gained possession of several important places in Brandenburg; but as he was pursuing his conquests, the marquis, reinforced by 14,000 Germans led by the Duke of Schonenburg, ventured to lay siege to Dantzic, after having ravaged the neighbouring country. The Dantzicers, however, defended themselves so bravely that the besiegers were soon obliged to relinquish their enterprise; whilst in their retreat they were attacked by a strong detachment of Polish cavalry, who made prodigious havoc amongst them, compelling the wretched remains to take shelter in Pomerania, where they were massacred by the peasants. Soon after this the marquis was obliged to submit to the clemency of the conqueror. To secure him in his interest, however, Sigismund granted him half the province of Prussia as a secular duke, dependent on the crown of Poland.

In the reign of Sigismund the kingdom of Poland may be considered as having attained its greatest pitch of glory. This monarch possessed, in his own person, the republic of Poland, the great duchies of Lithuania, Smolensko, and Saveria, besides vast territories lying beyond the Euxine and the Baltic; whilst his nephew Louis possessed the kingdoms of Bohemia, Hungary, and Silesia. But this glory received a sudden check in 1548, by the defeat and death of Louis, who perished in a battle fought with Solyman the Great, sultan of the Turks. The daughter of this prince had married Ferdinand of Austria, an alliance by which the dominions of Hungary, Bohemia, and Silesia became inseparably connected with the hereditary dominions of the Austrian family. Sigismund, then in the eighty-fourth year of his age, did not survive the news of this defeat many months, but died of a lingering disorder, leaving behind him the character of a complete general, an able politician, a good prince, and one of the strongest men in the North.

Sigismu II.

Sigismund Augustus, who succeeded his father Sigismund I., proved also a very fortunate prince. At that time the most violent and bloody wars were carrying on in Germany, and indeed throughout other parts of Europe, on account of religion; but Sigismund wisely avoided interfering in these disputes. He would not admit into his dominions any of those divines who were taxed with holding heterodox opinions, nor even allow his people the liberty of corresponding with them; yet he never persecuted, nor employed any other means for the preservation of the state than those of a well-conducted and regular policy. He applied himself diligently to the reforming of abuses, enforcing the laws, enriching the treasury, promoting industry, and redeeming the crown-lands where the titles of the possessors appeared illegal. Out of the revenue recovered in this manner he raised a formidable standing army without laying any additional tax upon his subjects; and though he preferred peace to war, he was always able to punish those who offered indignities to his person or his crown.

His knowledge of the art of war was soon tried in a contest with the Russians, who, encouraged by the disputes which had subsisted between the Teutonic knights and the Archbishop of Riga, cousin of Sigismund, had made an irruption into Livonia. The province was at that time divided between the knights and the prelate; and the Russians, under pretence of assisting the former, had seized great part of the dominions of the latter. The archbishop had recourse to his kinsman the King of Poland, who, after fruitless efforts to accommodate matters, marched towards the frontiers of Livonia with an army of 100,000 men. The knights were in no condition to resist such a formidable power; and therefore, deserting their allies, they put themselves under the protection of the King of Poland. But the czar, John Basilides, though deserted by the knights, did not lose his courage. His army consisted of 300,000 men, with whom he imagined himself able to reduce all Livonia, in spite of the utmost efforts of the King of Poland; but having met with some checks in that quarter, he directly invaded Poland with his whole army. At first he carried everything before him; but the Poles soon made a vigorous opposition; and the Russians, though everywhere defeated, still continued their incursions, which Sigismund at last revenged by invading Russia in his turn.

These mutual desolations and ravages at last made both parties desirous of peace, and a truce for three years was agreed on; but during the continuance of the armistice the King of Poland died, and with him was extinguished the house of Jagellon, which had governed Poland for nearly two hundred years. On the death of Sigismund, Poland became a prey to intestinal divisions; and intrigues were set on foot at the courts of Vienna, France, Saxony, Sweden, and Brandenburg, each of them endeavouring to establish a prince of their nation on the throne of Poland. The result of all this was, that the kingdom became one universal scene of corruption, faction, and confusion. The members of the diet consulted only their own interest, and were ready on every occasion to sell themselves to the best bidder. The Protestants had by this time got a considerable footing in the kingdom, and thus religious disputes were intermingled with political ones. One good effect, however, flowed from this confusion. A law was passed, by which it was enacted that no difference in religious opinions should occasion any contention amongst the subjects of the kingdom; that all the Poles, without discrimination, should be capable of holding public offices and trusts under the government; and that the future kings should swear expressly to cultivate the internal tranquillity of the realm, and to cherish without distinction their subjects of all persuasions.

Henry II., Duke of Anjou.

Whilst the candidates for the throne were severally attempting to support their own interest in the best manner they could, John Crasoski, a Polish gentleman of great merit, but diminutive stature, had just returned from France, whither he had travelled for improvement. His humour, wit, and diverting size had rendered him universally agreeable at the court of France, and in a particular manner engaged the esteem of Catharine de' Medicis, which the little Pole had the address to make use of for his own advantage. He owed many obligations to the Duke of Anjou, whom, out of gratitude, he represented in such favourable terms, that the Poles began to entertain thoughts of making him their king. These sentiments were confirmed and encouraged by Crasoski, who returned into France by order of several leading men in Poland, and acquainted the king and queen-mother that nothing was wanting except the formality of an embassy to procure the crown for the Duke of Anjou, almost without opposition. Charles IX., king of France, at that time also promoted the scheme; being jealous of the Duke of Anjou's popularity, and willing to have him removed to as great a distance as possible. The parties accordingly came to an agreement, in which it was stipulated that the Duke of Anjou should maintain the laws, liberties, and customs of the kingdom of Poland, and of the grand duchy of Lithuania; that he should transport all his effects and annual revenues in France into Poland; that the French monarch should pay the late King Sigismund's debts; that he should maintain a hundred young Polish gentlemen at his court, and fifty in other places; that he should send a fleet to the Baltic to assist Poland against the Russians; and, lastly, that Henry should marry the Princess Anne, sister of the late King Sigismund, though this article Henry refused to ratify till his return to Poland. Everything being thus settled, the young king quitted France, attended by a splendid retinue, and was accompanied by the queen-mother as far as Lorraine. He was received by his subjects on the frontiers of Poland, and conducted to Cracow, where he was soon afterwards crowned. The affections of the Poles were soon engaged by the youth and accomplishments of Henry; but scarcely had he been seated on the throne, when, by the death of Charles IX., he became heir to the crown of France. Being informed of this by repeated messages from Catharine, he repented his having accepted the crown of Poland, and resolved to leave it for that of France. But being sensible that the Poles would oppose his departure, he kept his intentions secret, and watched an opportunity of stealing out of the palace in disguise during the night-time. The Poles, as might well be expected, were irritated at being thus abandoned, from the mere motive of interest, by a prince whom they had so much loved and honoured. Parties were despatched after him by different roads; and Zamoski, a nobleman who headed one of these parties, overtook him some leagues distant from Cracow. All the prayers and tears of that nobleman, however, could not prevail on Henry to return; he rode post to Vienna, and then passed into France by the way of Italy. On the 15th of July 1575 he was in full diet solemnly divested of the regal dignity, and the throne declared vacant.

Batory.

After the deposition of Henry, commotions and factions again occurred, but the contending parties were now reduced to two,—one who supported the interest of Maximilian, Emperor of Germany; and the other, who were for electing the Princess Anne, and marrying her to Stephen Batory, prince of Transylvania. The latter prevailed; and Batory having married the princess, was crowned on the 1st of May 1576. No opposition was made to his authority, except by the inhabitants of Dantzic, who adhered to the interest of Maximilian, and after his death had the presumption to demand from the king an oath acknowledging their absolute freedom and independence. This led to a war in which the people of Dantzic were worsted; but it was not until after suffering severely that they were at length induced to submit.

The war with Dantzic had no sooner been ended than the king directed his whole strength against the Czar of Muscovy, who had laid siege to Revel, and made himself master of several important cities in Livonia. The czar behaved everywhere with the greatest cruelty, slaughtering without distinction all who were able to bear arms, and abandoning the women and children to the brutality of the Tartars who served in the army. At length, in 1578, a body of forces was despatched into the province; the towns of Wender and Dwinaburg were surprised; and an army sent by the czar to surprise the former was defeated. That unhappy province was at this time also invaded by the Swedes, who professed themselves to be enemies equally to both parties, and who in cruelty were scarcely inferior to the Russians themselves. The king, however, nothing daunted by the number of his adversaries, called to his assistance Christopher, prince of Transylvania, with all the standing forces of that country, and took the field in person against the Muscovites. He laid siege to Polocz, a town of great importance, situated on the river Dwina; and the Russians, in order to strike terror into the enemy, put to death all the citizens of the town. The river was dyed with blood, and a vast number of human bodies, fastened to planks and terribly mangled, were carried down the stream. But this barbarity, instead of intimidating the Poles, irritated them to such a degree that nothing could resist them. Finding that their cannon made little impression upon the walls of the city, which were constructed of wood, they advanced to the assault with burning torches in their hands, and reduced them to ashes. The Russian barbarians were thus obliged to surrender at discretion; and it reflects the highest honour on Batory that, notwithstanding the dreadful instances of cruelty which he had before his eyes, he did not suffer his soldiers to retaliate.

After the reduction of Polocz, Batory continued the war, and with great success. Two detachments from the army penetrated the enemy's country by different roads, wasted all before them to the gates of Smolensko, and returned with the spoils of 2000 villages which they had pillaged and destroyed. The czar was obliged to sue for peace, which he obtained on condition of relinquishing Livonia, after having thrown away the lives of more than 400,000 of his subjects in attempting to conquer it.

A peace was likewise concluded with the Swedes, and Batory being thus freed from war, applied himself to the internal government of his kingdom. He regulated the Polish cavalry in such a manner that they became formidable to the Turks and other neighbouring nations; and this is the military establishment to which the Poles have given the name of *quartienne*, because a fourth part of the revenue was employed in supporting it. Batory sent this body of cavalry towards the frontiers of Tartary, and by its means the Ukraine, a vast tract of desert country, was filled with flourishing towns and villages, and became a strong barrier against the Turks, Tartars, and Russians. The last memorable action of this prince was his attaching to Poland the Cossacks, whom he civilized and instructed in the arts of war and peace. All kinds of manufactures at that time known in Poland were likewise introduced among the Cossacks; the women were employed in spinning and weaving woollen cloths, whilst the men were taught agriculture and the mechanical arts.

Whilst Batory was employed in this manner, the Swedes broke the convention into which they had entered with Poland, and were on the point of obtaining possession of Riga. To this, indeed, Batory himself had given occasion, by attempting to impose the Catholic religion upon the inhabitants, after having promised them entire liberty of conscience; a proceeding which so irritated them that they revolted, and were on the point of admitting a Swedish garrison into the city, when the king became informed of what was going forward. He resolved to take a most exemplary vengeance on the inhabitants of Riga; but before he could execute his intention, he died in 1586, the fifty-fourth year of his age, and tenth of his reign.

Sigismund III.

The death of Batory involved Poland in fresh troubles. Four candidates appeared for the crown: the princes Ernest and Maximilian, of the House of Austria; Sigismund, prince of Sweden; and Theodore, czar of Muscovy. Each of these had a separate party; but Sigismund and Maximilian managed matters so cleverly that in 1587 both of them were elected. The result was a civil war, in which Maximilian was defeated and taken prisoner; and thus, without opposition, Sigismund III., surnamed Vasa, obtained the throne of Poland. He waged a successful war with the Tartars, and was otherwise prosperous; but though he succeeded to the crown of Sweden, he found it impossible for him to retain both kingdoms, and he was formally deposed from the Swedish throne. In 1610 he conquered Russia, and placed his son on the throne of that country; but the Polish conquests of that country have always been short-lived. The young prince was soon afterwards deposed; and the Russians not only regained their liberty, but began to make encroachments on Poland itself. A very unfortunate war also took place with Sweden, which was now governed by the great Gustavus Adolphus; but the particulars of that contest, with the other exploits of that renowned warrior, are elsewhere related. At last, Sigismund, worn out with cares and misfortunes, died in 1632.

Uladislas VII.

John Casimir.

After Sigismund's death the affairs of Poland seemed to revive a little under Uladislas VII., who obliged the Russians to sue for peace, and Sweden to restore some of her conquests; but an attempt being made to abridge the liberty of the Cossacks, they revolted, and gave the Poles several terrible defeats; nor did the war terminate in the lifetime of Uladislas, who died in 1648. His successor, John Casimir, concluded a peace with these dangerous enemies, but the war was soon after renewed; and whilst the kingdom was distracted between the hostility of the Cossacks and the discontents of its own inhabitants, the Russians took the opportunity of invading and pillaging Lithuania.

Michael Wieçnowieçki.

In a little time afterwards, the whole kingdom was subdued by Charles Gustavus, successor to Christina, Queen of Sweden. Happily for Poland, however, a rupture took place between the courts of Sweden and Copenhagen, and the Poles were thereby enabled to drive out the Swedes in 1657. This was succeeded by civil wars and contests with Russia, which so much vexed the king that he resigned the crown in 1668. For two years after the resignation of Casimir the kingdom was filled with confusion; but on the 17th September 1670, one Michael Koributh Wieçnowieçki, collaterally descended from the House of Jagellon, though in a very mean situation at that time, was chosen king. His reign continued only for three years, during which time John Sobieski, a celebrated Polish general, gave the Turks a dreadful overthrow, though their army consisted of more than 300,000 men; and if this blow had been followed up, the Cossacks would not only have been entirely subdued, but very advantageous terms might have been obtained from the sultan. Of that vast multitude of Turks, no more than 15,000 made their escape, the rest being all either killed or taken. However, the Polish soldiers, being only bound by the laws of their country to stay a certain time in the field, refused to pursue this signal victory, and suffered the king to make peace on any terms he could procure.

John Sobieski.

Wieçnowieçki died before the news of this transaction reached Cracow; and after his death a new scene of confusion ensued, till at last the fortune of John Sobieski prevailed, and he was elected king of Poland in 1674. He was a most magnanimous and heroic prince, and by his valour and good conduct retrieved the affairs of Poland. The Turks were everywhere defeated; but notwithstanding his great qualities, Poland was now so thoroughly corrupted, and pervaded by such a spirit of disaffection, that the latter part of this monarch's reign was involved in troubles, through the ambition and contention of some powerful noblemen. Sobieski died in 1696, and with him the glory of Poland descended into the tomb.

Augustus

Most violent contests now took place about the succession, but the recital of these would far exceed our limits. At last, Frederick Augustus, elector of Saxony, prevailed; but as some of the most essential ceremonies were wanting in his coronation, because the primate, who was in an opposite interest, would not perform them, he found it extremely difficult to keep his subjects in proper obedience; and, to add to his misfortunes, having engaged in a league with Denmark and Russia against Sweden, he was attacked with irresistible fury by Charles XII. The particulars of this war, however, as they form great part of the exploits of that northern hero, more properly fall to be related under the head of Sweden. Here, therefore, we shall only observe, that Augustus was reduced to the humiliating necessity of renouncing the crown of Poland on oath, and even of congratulating his rival Stanislas upon his accession to the throne. But when the power of Charles was broken by his defeat at Pultowa, the fortune of Augustus again prevailed; Stanislas was driven out; and the former, being absolved from his oath by the pontiff, resumed possession of the throne of Poland.

Degeneracy of the Poles.

After this Poland makes no figure, except in the history of political iniquity. Weakened by internal dissensions, it became unable to resist foreign aggression, and fell an easy prey to the ambitious powers by which it was surrounded. On 5th October 1763, Augustus II., elector of Saxony and king of Poland, died, and was succeeded by Count Poniatowski, a Polish grandee, who, on 7th September 1764, was proclaimed king by the name of Stanislas Augustus, and crowned on 25th November the same year. During the interregnum which took place between the death of Augustus III. and the election of Stanislas, a decree had been passed by the convocation-diet of Poland, with regard to the Dissidents, as they were called, or dissenters from the Catholic faith, by which they were prohibited the free exercise of their religion, and excluded from all offices and places under the government. On this occasion several of the European powers interposed, and the courts of Russia, Prussia, Great Britain, and Denmark, tendered remonstrances to the Diet; but, notwithstanding these, the decree was confirmed by the coronation-diet held soon after the king's election.

Interference of foreign powers in behalf of the Dissidents.

On the 6th of October 1766, an ordinary Diet was assembled. Here declarations from the courts above mentioned were presented to his Polish majesty, requiring the re-establishment of the Dissidents in their civil rights and privileges, and the peaceable enjoyment of their modes of worship secured to them by the laws of the kingdom, which had been observed for two centuries. These privileges, it was alleged, had been confirmed by the treaty of Oliva, concluded by all the northern powers, and could not now be altered except by the consent of all the contracting parties. The Catholic party contended strongly for a confirmation of some decrees against the Dissidents, made in the years 1717, 1723, and 1736. The deputies from the foreign powers replied, that those decrees had passed in the midst of intestine troubles, and were contradicted by the formal protestations and express declarations of those powers. At last, after a violent contest, the matter was referred to the bishops and senators for their opinion; and upon a report from them, the Diet came to a resolution that they would maintain the Dissidents in all the rights and prerogatives to which they were entitled by the laws of their country and by treaties; and that as to their complaints with regard to the exercise of their religion, the college of archbishops and bishops, under the direction of the prince primate, would endeavour to remove all those difficulties in a manner conformable to justice and charity. In the mean time, the court of Russia, resolved to enforce her remonstrances, marched a body of troops to within a few miles of Warsaw. These resolutions of the Diet were by no means agreeable to the Dissidents. The latter dated the beginning of their sufferings from the year 1717. Referring their grievances to the archbishops and bishops was looked upon as a measure the most unreasonable that could be imagined, as that body of men had always been their opponents, and in fact the authors of the evils which had befallen them. When matters came to be considered in this view, an additional body of Russians, to the number of about fifteen thousand, entered Poland.

Consequences of this interference.

The Dissidents, being now pretty sure of the protection of foreign powers, entered, on the 20th of March 1767, into two confederacies, at Thorn and Sluck. One of these was signed by the Dissidents of Great and Little Poland, and the other by those of the grand duchy of Lithuania. The purpose of these confederacies was, an engagement to exert themselves in the defence of their ancient privileges, and the free exercise of their religion; professing at the same time the utmost loyalty to the king, and resolving to send to him a deputation to implore his protection. They even invited those of the Catholic communion, and all true patriots, to unite with them in maintaining the fundamental laws of the kingdom, the peace of religion, and the rights of men in society. They also claimed, by virtue of public treaties, the protection of the powers who were guarantees of their liberties, namely, Russia, Sweden, Great Britain, Denmark, and Prussia. And they protested, that they had no intention of acting to the detriment of the Roman Catholic religion, which they duly respected, but only asked liberty for their own, and the re-establishment of their ancient rights. The three cities of Thorn, Elbing, and Dantzig, acceded to the confederacy of Thorn on the 10th of April; as did the duke and nobles of Courland to that of Sluck on the 15th of May. In the mean time the empress of Russia and the king of Prussia continued to issue forth new declarations in favour of the Dissidents; and the Russian troops in Poland were gradually augmented to thirty thousand men. Great numbers of other confederacies were also formed in different parts of the kingdom; but these at first took little part in the affair of the Dissidents. They complained chiefly of the administration of public affairs, in which they alleged that innovations had been introduced, and were therefore for some time called Confederations of Malcontents. All these confederacies published manifestos, in which they recommended to the inhabitants to receive and treat the Russian troops as the defenders of the liberties of Poland.

General confederacy.

The different confederacies of malcontents formed in the twenty-four districts of Lithuania united at Wilna on the 22d of June; and that general confederacy re-established Prince Radzivil, who had married the king's sister, in his liberty, estates, and honour, of which he had been deprived in 1764 by the states of that duchy. On the 23d of June Prince Radzivil was chosen grand marshal of the general confederacy of all Poland, which then began to be called the National Confederacy, and was said to be composed of seventy-two thousand noblemen and gentlemen. The general confederacy now took such measures as appeared most proper for strengthening their party. They sent to the several woivodes of the kingdom, requiring that all the gentlemen who had not signed the confederacy should do it immediately; that all the courts of justice should subsist as formerly, but not judge any of the confederates; that the marshals of the crown should not pass any sentence without the participation of at least four of the confederates; and that the marshals of the crown and the treasurers should be immediately restored to the possession of their respective rights. In the mean time the Catholic party were not idle. The bishop of Cracow sent a letter to the Diet assembled at Warsaw on the 13th of August, in which he exhorted them to arm their nuncios with courage, by giving them orthodox and pious instructions, that they might not grant the Dissidents new advantages beyond those which were secured to them by the constitutions of the country and the treaties with foreign powers. The pope also sent briefs to the king, the great chancellor, the nobility, the bishops of the kingdom, and to the prince primate, with such arguments and exhortations as were thought most calculated to ward off the impending danger. Councils in the mean time were frequently held at the bishop of Cracow's palace, where all the prelates at Warsaw assembled. On the 26th of September 1767 the confederacy of Dissidents was united with the general confederacy of malcontents in the palace of

Prince Radzivil, who on that occasion expressed great friendship for the Dissidents. In a few days afterwards the Russian troops in the capital were reinforced, and a considerable body of them was posted at about five miles distance.

Tumults in the Diet.

On the 5th of October an extraordinary Diet was held. But the affair of the Dissidents met with such opposition, that it was thought necessary to adjourn the meeting till the 12th, during which interval every expedient was used to gain over those who opposed Prince Radzivil's plan. This was, to appoint a commission furnished with full power to enter into conference with Prince Repnin, the Russian ambassador, concerning the affairs of the Dissidents. But notwithstanding all the pains taken, the meeting of the 12th proved exceedingly tumultuous. The bishops of Cracow and Kiow, with some other prelates, and several magnates, declared that they would never consent to the establishment of such a commission; and at the same time they spoke with more vehemence than ever against the pretensions of the Dissidents. Some of the deputies replied with great warmth; and this occasioned such animosities, that the meeting was again adjourned till the 16th.

Violent proceedings of the Russians.

On the 13th the bishops of Cracow and Kiow, the palatine of Cracow, and the starost of Domski, were carried off by Russian detachments. The crime alleged against them, in a declaration published next day by Prince Repnin, was, that they had been wanting in respect to the dignity of the empress of Russia, by attacking the purity of her intentions towards the republic; though she was resolved to continue her protection and assistance to the general confederacy united for preserving the liberties of Poland, and correcting all the abuses which had been introduced into the government of that country.

Confederacy of Bar.

It was probably owing to this violent proceeding of the Russians that Prince Radzivil's plan was at last adopted, and several new regulations were made in favour of the Dissidents. These innovations, however, soon produced a civil war, which at last ended in the ruin of the kingdom. In the beginning of the year 1768, a new confederacy was formed in Podolia, a province bordering on Turkey; it was afterwards called the Confederacy of Bar, and the intention of it was to abolish, by force of arms, the new constitutions, particularly those in favour of the Dissidents. The members of the new confederacy likewise expressed great indignation at the carrying away the bishops of Cracow, Kiow, and others, and still detaining them in custody.

Podolia was reckoned the fittest place for the purpose of the confederates, who imagined that the Russians could not attack them there without giving umbrage to the Ottoman court. Similar confederacies, however, were quickly entered into throughout the kingdom. The clergy excited all ranks of men to exert themselves in defence of their religion; and so effectual did their exhortations prove, that even the king's troops could not be trusted to act against these combinations. The empress of Russia threatened the new confederates as disturbers of the public tranquillity, and declared, that if they persisted, her troops would act against them. It was some time, however, before the Russian troops were considerably reinforced; nor did they at first seem inclined to act with the vigour that they might have exerted. A good many skirmishes soon occurred between the contending parties, in which the confederates were for the most part defeated. In one of these encounters, the latter being worsted, and hardly pressed, a number of them passed the Dniester and took refuge in Moldavia. This province had formerly belonged to Poland, but was now subject to the grand signior. The Russians, however, pursued their enemies into Moldavia; but in order to prevent any offence being taken by the Porte, Prince Repnin wrote to the Russian resident at Constantinople, that the conduct of the Russian colonel who commanded the party was quite contrary to the orders of his court, and that he would therefore be dismissed.

War between this confederacy and the Russians.

Great cruelty was in the mean time exercised against the Dissidents where there were no Russian troops to protect them. Towards the end of October 1768, Prince Martin Lubomirski, one of the southern confederates, who had been driven out of Poland, and had taken shelter with some of his adherents amongst the mountains of Hungary, caused a manifesto to be posted up on several of the churches of Cracow, in which he invited the nation to a general revolt, assuring them of the assistance of the Ottoman Porte, with whom he pretended to have concluded a treaty. The unhappy kingdom of Poland became the first scene of this war, and in a short time it was reduced to the most deplorable situation. In the end of the year 1768, the peasants of the Greek faith in the Ukraine took up arms, and committed the greatest ravages, having, as they pretended, been threatened with death by the confederates unless they would become Roman Catholics. Against these insurgents the Russians employed their arms, and made great numbers of them prisoners. The rest took refuge amongst the Haidamacks, by whom they were soon joined, and in the beginning of 1769 they entered the Ukraine, committing everywhere the most horrid massacres. Here, however, they were at last defeated by the Polish troops, at the same time that several of the confederacies in Poland were severely chastised. Soon afterwards, the khan of the Crim Tartars having been repulsed with loss in an attempt on Servia, entered the Polish territories, where he left frightful marks of his inhumanity; which, with the cruelties exercised by the confederates, induced the Polish Cossacks of Braclau and Kiovia, amounting to near thirty thousand effective men, to join the Russians, in order to defend their country against these destroyers. Matters continued much in the same state during the rest of the year 1769; and in 1770 skirmishes frequently occurred between the Russians and confederates, in which the latter were almost always worsted; but they took care to revenge themselves by the most barbarous cruelties on the Dissidents, wherever they could find them. In 1770, a considerable number of the confederates of Bar, who had joined the Turks, and been excessively ill used by them, came to an accommodation with the Russians, who took them under their protection upon very moderate terms. In the mean time agriculture had been so much neglected, that the crop of 1770 proved deficient. This encouraged a number of desperadoes to associate, who, under the denomination of Confederates, were guilty of still greater excesses than those who had been under some kind of regulation; and thus a great part of the country was at last reduced to a mere desert, the inhabitants being either exterminated, or carried off to stock the remote Russian plantations.

New confederacies.

In the year 1771, the confederacies, which appeared to have been extinguished, sprang up afresh, and increased to a great degree. This was occasioned by their having been secretly encouraged and supplied with money by France. A great number of French officers also engaged as volunteers in their service; and having introduced discipline amongst their troops, they acted with greater vigour than formerly, sometimes proving more than a match for their enemies. But these gleams of success served only to light them on to their ruin. The Russians were reinforced and properly supported. The Austrian and Prussian troops entered the country, advancing on different sides; and in a short time the confederates found themselves entirely surrounded by enemies, who seemed to have nothing less in view than an absolute conquest of the country, and sharing it amongst themselves.

Attempt to assassinate the king.

Before matters came to this crisis, however, the confederates had formed a design of assassinating the king, on account of his supposed attachment to the Dissidents. A Polish nobleman, named Pulaski, a general in the army of the confederates, was the person who planned the enterprise; and the conspirators who carried it into execution were about forty in number, headed by three chiefs, named respectively Lukawski, Strawenski, and Kosinski. On the 2d of September they obtained admission into Warsaw, unsuspected and undiscovered. On Sunday night, the 3d of September 1771, a few of these conspirators remained in the skirts of the town; but the others repaired to the place of rendezvous, the street of the Capucins, where his majesty was expected to pass about his usual hour of returning to the palace. The king had been to visit his uncle Prince Czartoryski, grand chancellor of Lithuania, and was on his return from thence to the palace between nine and ten o'clock. He was in a coach, accompanied by at least fifteen or sixteen attendants, besides an aide-de-camp in the carriage. Scarcely was he at the distance of 200 paces from Prince Czartoryski's palace, when he was attacked by the conspirators, who commanded the coachman to stop on pain of instant death. They fired several shots into the carriage, and almost all the other persons who preceded and accompanied his majesty were dispersed; the aide-de-camp having also abandoned him, and attempted to conceal himself by flight. The king himself attempted to escape under cover of the night, which was extremely dark, but they immediately laid hold of him by the collar, and, mounting on horseback, dragged him along the ground between their horses at full gallop for nearly 500 paces through the streets of Warsaw. Finding that he was incapable of following them on foot, they set him on horseback, and then redoubled their speed for fear of being overtaken.

The night was exceedingly dark, and they were absolutely ignorant of the way; so that they wandered through the open meadows without getting to any distance from Warsaw. At length they were suddenly alarmed by a Russian patrole or detachment, and instantly a number of the assassins disappeared, leaving only three with the king. Scarcely a quarter of an hour after, a second Russian guard challenged them anew, and two of the assassins then fled, leaving Kosinski alone with the king. At length, by means of expostulation and entreaty, the king prevailed on Kosinski to restore him to liberty, and upon his return to Warsaw, he was received with the utmost demonstrations of joy. But neither the virtues nor the popularity of the sovereign could allay the factious spirit of the Poles, nor prevent the dismemberment of his kingdom.

First partition of Poland.

The partition of Poland was first projected by the King of Prussia. Polish or Western Prussia had long been an object of his ambition. Exclusively of its fertility, commerce, and population, its local situation rendered it highly valuable to that monarch: it lay between his German dominions and Eastern Prussia, and whilst in the possession of the Poles it cut off at their will all communication between them. The period had now arrived when the situation of Poland seemed to promise the easy acquisition of this valuable province. Frederic, however, pursued it with all the caution of an able politician. On the commencement of the troubles, he showed no eagerness to interfere in the affairs of this country; and although he had concurred with the Empress of Russia in raising Stanislas Augustus to the throne of Poland, yet he declined taking any active part in his favour against the confederates. Afterwards, when in 1769 the whole kingdom became convulsed with civil commotions, and desolated by the plague, he, under pretence of forming lines to prevent the spreading of the infection, advanced his troops into Polish Prussia, and occupied the whole of that district. Though now completely master of the country, and by no means apprehensive of any formidable resistance from the disunited and distracted Poles, yet, as he was well aware that the security of his new acquisition depended upon the acquiescence of Russia and Austria, he planned the partition of Poland. He communicated the project to the emperor, either upon their interview at Niess in Silesia in 1769, or in that of the following year at Nieustadt in Austria, and from him the overture met with a ready concurrence. To induce the Empress of Russia to acquiesce in the same project, he despatched to St Petersburg his brother Henry, who suggested to the empress that the House of Austria was forming an alliance with the Porte, with which she was then at war; that if such alliance took place, it would create a most formidable combination against her; that nevertheless the friendship of that house was to be purchased by acceding to the partition; that, upon this condition, the emperor was willing to renounce his connection with the grand signior, and would suffer the Russians to prosecute the war without interruption. Catharine, anxious to push her conquests against the Turks, and dreading the interposition of the emperor in that quarter; perceiving, likewise, from the intimate union between the courts of Vienna and Berlin, that it would not be in her power at the present juncture to prevent the intended partition; closed with the proposal, and selected no inconsiderable portion of the Polish territories for herself. The treaty was signed at St Petersburg in the beginning of February 1772, by the Russian, Austrian, and Prussian plenipotentiaries. It would be tedious to enter into a detail of the pleas urged by the three powers in favour of their several demands; nor would it be less uninteresting to lay before the reader the answers and remonstrances of the king and Senate, as well as the appeals to the other states which had guaranteed the possessions of Poland. The courts of London, Paris, Stockholm, and Copenhagen remonstrated against these usurpations; but remonstances without assistance could be of no effect. Poland submitted to the dismemberment not without the most violent struggles; and now for the first time that unhappy country felt and lamented the fatal effects of faction and discord.

A Diet being demanded by the partitioning powers, in order to ratify the cession of the provinces, it met on the 19th of April 1773; and such was the spirit of the members that, notwithstanding the deplorable situation of their country, and the threats and bribes of the three powers, the partition-treaty was not carried through without much difficulty. For some time the majority of the nuncios appeared determined to oppose the dismemberment, and the king firmly persisted in the same resolution. The ambassadors of the three courts enforced their requisitions by the most alarming menaces, and threatened the king with deposition and imprisonment. They also gave out by their emissaries that, in case the Diet continued refractory, Warsaw should be pillaged. This report was industriously circulated, and made a sensible impression upon the inhabitants. By menaces of the same sort, by corrupting the marshal of the Diet, and by bribes, promises, and threats, the members were at length prevailed on to ratify the dismemberment.

The partitioning powers, however, did less injury to the republic by dismembering its fairest provinces than perpetuating the principles of anarchy and confusion. Under pretence of amending the constitution, they confirmed all its defects, and took effectual precautions to render this unhappy country incapable of ever emerging from the deplorable state into which it had fallen, as was seen in the failure of the most patriotic attempt ever made by a king to reform the constitution of his kingdom.

Government.

The kings of Poland were anciently hereditary and absolute, but afterwards became elective and limited. In the reign of Louis, towards the end of the fourteenth century, several limitations were imposed on the royal prerogative. In that of Casimir IV., who ascended the throne in 1445, representatives from the several palatinates were first called to the Diet; the legislative power till then having been lodged in the states, and the executive in the king and Senate. On the decease of Sigismund Augustus, it was enacted by law that for the future the choice of a king should perpetually remain free and open to all the nobles of the kingdom; and this law was accordingly observed, to the great injury of the kingdom.

As soon as the throne became vacant, the authority was transferred to the primate, who in quality of interrex, had in some respects more power than the king himself. He notified the vacancy of the throne to foreign princes, and issued the *universalia*, or circular letters for the election.

The place of election was the field of Vola, at the gates of Warsaw; and all the nobles of the kingdom had a right of voting. The Poles encamped on the left side of the Vistula, and the Lithuanians on the right, each under the banners of their respective palatinates. The field of election was surrounded by a ditch provided with three gates; one to the east for Great Poland, another to the south for Little Poland, and a third to the west for Lithuania. In the middle of the field was erected a great building of wood, named the *Szopa*, or Hall of the Senate. All who aspired openly to the crown were expressly excluded from the field of election, that their presence might not constrain the voters. The king must be elected *nemine contradicente*, by all the suffrages without exception. The primate in few words recapitulated to the nobles on horseback the respective merits of the candidates; he exhorted them to choose the most worthy, invoked heaven, gave his blessing to the assembly, and remained alone with the marshal of the Diet, while the senators dispersed themselves into the several palatinates to promote a unanimity of sentiment. If they succeeded, the primate himself went to collect the votes, at the same time naming again all the candidates. "Szoda," answered the nobles, "that is the man we choose;" and instantly the air resounded with his name, together with cries of "*Vivat*," and the noise of pistols. If all the palatines agreed in their nominations, the primate got on horseback, and then, the profoundest silence succeeding to the greatest noise, he asked three times if all were satisfied, and after a general approbation, three times proclaimed the king; upon which the grand marshal of the crown repeated the proclamation three times at the three gates of the camp.

The *pacta conventa*.

Before the king was proclaimed, the *pacta conventa* were read aloud to him, which, on his knees at the altar, he swore to observe. This contract, which had been drawn up, methodized, and approved by the Senate and nobility, was deemed the great part of the charter of Poland. It provided that the king should not attempt to encroach on the liberty of the people by rendering the crown hereditary in his family; that he should preserve all the customs, laws, and ordinances respecting the freedom of election; that he should ratify all treaties subsisting with foreign powers, which were approved by the Diet; that it should be his chief study to cultivate peace, preserve the public tranquillity, and promote the interest of the realm; that he should not coin money except in the name of the republic, or appropriate to himself the advantages arising from coinage; that in declaring war, concluding peace, making levies, hiring auxiliaries, or admitting foreign troops upon any pretext within the Polish dominions, the consent of the Diet and Senate should be necessary; that all offices and preferments should be given to natives of Poland and Lithuania; that the king should not marry without the approbation of the Senate; that he should administer justice by the advice of the Senate and his council; that he should not diminish the treasure kept at Cracow; but, on the contrary, endeavour to augment it, as well as the number of the crown jewels; that he should not borrow money without the consent of the Diet; that he should not equip a naval force without the consent and full approbation of the republic; that he should profess the Roman Catholic faith, and promote, maintain, and defend it, throughout all the Polish dominions; and, finally, that all their several liberties, rights, and privileges should be preserved to the Poles and Lithuanians in general, and to all the districts and provinces contained within each of these great divisions, without change, alteration, or the smallest violation, except by the consent of the republic.

The Diet.

The Diet of Poland was composed of the king, the Senate, the bishops, and the deputies of the nobility or gentry of every palatinate, called, in their collective capacity, *comitia togata*, that is, when the states assembled in the city without arms and horses; or *comitia paludata*, when they met in the fields armed, as during an interregnum, at the Diet of election. When it was proposed to hold a general Diet, the king, or, in case of an interregnum, the primate, issued writs to the palatines of the several provinces, specifying the time and place of the meeting. A sketch likewise was sent of the business to be deliberated on by the assembly; the Senate was consulted in this particular, and six weeks were allowed the members to prepare themselves for the intended session. The Diet never sat more than six weeks even in the most critical conjunctures and pressing emergencies. On receipt of the king's writ, the palatine communicated the meeting of the Diet to all the castellans, starosts, and other inferior officers and gentry within his jurisdiction; requiring them to assemble on a certain day to elect deputies, and take into consideration the business specified in the royal summons. These meetings were called petty diets, *dietines* or *lantage*, in the language of the country, every gentleman possessing three acres of land having a vote, and matters being determined by a majority; whereas in the general Diet decrees were only valid when the whole body was unanimous. Every palatinate had three representatives, though the business devolved on one called a nuncio, who was elected on account of his ability and experience; and the other two were added only to give weight to this leading member. As these deputies, since the reign of Casimir III., had seats in the Diet, it naturally divided the general assembly into two bodies, the upper and lower; the one being composed of the Senate, the superior clergy, and the great officers; and the other of the representatives of the palatinates, who prepared all business for the superior body.

Among the inconveniences which attended the constitution of the Diet of Poland was a spirit of venality in the deputies, and a general corruption, that possessed all ranks and degrees in that assembly. There, as in some other countries, the cry of liberty was kept up for the sake of private interest. Deputies came with a full resolution of profiting by their patriotism, and not lowering their voice without a gratification. Determined to oppose the most salutary measures of the court, they either withdrew from the assembly, and protested against all that should be transacted in their absence, or else excited such a clamour as rendered it necessary for the court to silence them by some lucrative pension, donation, or employment. Unanimity was necessary to the passing of any bill.

The Senate

Perhaps the most respectable department of the Polish government was the Senate, composed of the bishops, palatines, castellans, and ten officers of state, who derived a right from their dignities of sitting in that assembly, and amounting in all to 144 members, who were styled "senators of the kingdom," or "counsellors of the state," and had the title of Excellency,—a dignity supported by no pension or emoluments necessarily annexed to it. The Senate presided over the execution of the laws, and was the guardian of liberty, the judge of right, and the protector of justice and equity. All the members except the bishops, who were senators *ex officiis*, were nominated by the king, and took an oath to the republic before they were permitted to enter upon their functions. Their honours continued for life.

The Permanent Council.

Such was the constitution of Poland before being new-modelled by the partitioning powers. That it was in all respects a very bad one, needs no proof whatever. But those foreign reformers did not improve it. For two centuries at least the Poles had with great propriety denominated their government a republic, because the king was so exceedingly limited in his prerogative that he resembled more the chief of a commonwealth than the sovereign of a powerful monarchy. That prerogative, already too confined to afford protection to the peasants, groaning under the tyranny of the nobles, was, after the partition-treaty, still further restrained by the establishment of the Permanent Council, which was vested with the whole executive authority, leaving to the sovereign nothing but the name. The Permanent Council consisted of thirty-six persons, elected by the Diet out of the different orders of nobility; and though the king, when present, presided in it, he could not exert a single act of power without the consent of the majority of persons, who might well be called his colleagues.

That Stanislas should have laboured to extricate himself and the great body of the people from such unparalleled oppression, and that the more respectable portion of the nation should have wished to give to themselves and their posterity a better form of government, was surely very natural and very meritorious. The influence of the partitioning powers was indeed exerted to render the king contented with his situation. His revenues, which before did not exceed L.100,000, were now increased to three times that sum. The republic likewise agreed to pay his debts, amounting to upwards of L.400,000. It also bestowed on him, in hereditary possession, four starosties or governments of castles, with the districts belonging to them, and re-imbursed him for the money which he had laid out on account of the state. It was likewise agreed that the revenues of the republic should be raised to 33,000,000 of florins, or nearly L.2,000,000 sterling; and that the army should consist of 30,000 men. Soon after the conclusion of peace with Turkey, the Empress of Russia also made the king a present of 250,000 rubles, as a compensation for that part of his dominions which had fallen into her hands.

he new onstitution of 791.

These bribes, however, were not sufficient to blind the penetration of Stanislas, nor to cool the ardour of his patriotism. He laboured for posterity, and with such apparent success that, on the 3d of May 1791, a new constitution of the government of Poland was established by the king, together with the confederate states assembled in double number to represent the Polish nation. That this constitution was perfect, we are far from asserting; but it was probably as much so as the inveterate prejudices of the nobles would admit of. It deviated as little as possible from the ancient forms, and consisted of eleven articles respecting the government of the republic, to which were added twenty-one sections, regulating the dietines or primary assemblies of Poland.

The first article of this constitution established the Roman Catholic faith, with its various privileges and immunities, as the dominant national religion; but to all other people, of whatever persuasion, it secured peace in matters of faith, and the protection of government. The second article guaranteed to the nobility or the equestrian order all the privileges which it enjoyed under the kings of the House of Jagellon. The third and fourth articles granted to the free royal towns internal jurisdictions of their own; and exempted the peasants from slavery, declaring every man free as soon as he set his foot on the territory of the republic. The fifth article, after declaring, that in civil society all power should be derived from the will of the people, enacted that the government of the Polish nation should be composed of three distinct powers; the legislative, in the states assembled; the executive, in the king and the Council of Inspection; and the judicial power, in the jurisdictions existing or to be established. According to the sixth article, the Diet, or the legislative power, was to be divided into two houses,—viz., the House of Nuncios or deputies, and the House of Senate, where the king was to preside. The former, being the representative and central point of supreme national authority, was to possess the pre-eminence in the legislature; therefore all bills were to be decided first in this house. The Senate was to consist of bishops, palatines, castellans, and ministers under the presidency of the king.

These ordinary legislative Diets were to have an uninterrupted existence, and be always ready to meet. The length of sessions was to be determined by the law concerning diets. If convened upon some urgent occasion out of ordinary session, they were only to deliberate on the subject which occasioned such a call, or on circumstances which might arise out of it. No law or statute enacted by such ordinary Diet could be altered or annulled by the same. The majority of votes was to decide everything and everywhere. Every twenty-five years an extraordinary constitutional Diet was to be held for the revision of the constitution, and making such changes and alterations as might be found requisite. The seventh article intrusted to the king and his council the highest power of executing the laws. The duty of such executive power was to watch over the laws, and to see them strictly executed according to their import, even by means of public force, should it be found necessary. The throne was to cease to be elective, and on the death of the present king was to become hereditary in the family of the Elector of Saxony. Every king, on his accession, was to take a solemn oath to support the present constitution, and to fulfil the *pacta conventa*. The king's person was sacred and inviolable. As no act could proceed immediately from him, he could not in any manner be responsible to the nation; he was not an absolute monarch, but the father and the head of the people; and his revenues, as fixed by the *pacta conventa*, were to be sacredly preserved. All public acts, the acts of magistracies and the coin of the kingdom, were to bear his name. He had the right of pardoning those who were condemned to death, except the crimes were against the state; and in time of war he had the supreme command of the national forces, but he might appoint the commanders of the army, with the consent of the states. The nomination to all offices and dignities was vested in him. The king's Council of Inspection was to consist of the primate as the head of the clergy, and the president of the commission of education, or the first bishop *in ordine;* of five ministers,—viz., those of police, justice, war, finances, and foreign affairs; of two secretaries to keep the protocols, one for the council and another for the foreign department, but both with a decisive vote. The hereditary prince, on coming of age, and having taken the oath to preserve the constitution, might assist at all sessions of the council, but could have no vote therein.

The eighth article regulated the administration of justice. It constituted primary courts of justice for each palatinate or district, composed of judges chosen at the dietine; and appointed higher tribunals, one being erected in each of the three provinces into which the kingdom was divided, with which appeals might be lodged from the primary courts. It likewise appointed for the trial of persons accused of crimes against the state one supreme general tribunal for all classes, called a *comitial tribunal*, or court composed of persons chosen at the opening of every Diet.

The ninth article provided a regency during the king's minority, in case of his settled alienation of reason, or upon the emergency of his being made a prisoner of war. The three great divisions of the kingdom (Great and Little Poland, and Lithuania) were entitled to send sixty-eight deputies each to the House of Nuncios. Every possessor of land, however small, had the right of voting at the election of representatives to the Diet. Every person of the equestrian order that paid territorial tax to government was eligible to all the elective offices in his district.

This constitution opposed by Russia.

Such were the chief heads of the Polish constitution established by the king and the confederates in 1791. It cannot be compared with systems that have been matured by long experience; but it is surely infinitely superior to the motley form of government which, for a century previous, rendered Poland a perpetual scene of war, tumult, tyranny, and rebellion. Many of the corrupt nobles, however, perceiving that it would curb their ambition, deprive them of the base means which they had long enjoyed of gratifying their avarice by setting the crown to sale, and render it impossible for them to continue with impunity their tyrannical oppression of the peasants, protested against it, and withdrew from the confederates. This was nothing more than what might have been expected, or than what the king and his friends undoubtedly expected. But the malcontents were not satisfied with a simple protest; they preferred their complaints to the empress of Russia, who, ever ready on all occasions, and on the slightest pretence, to invade Poland, poured her armies into the republic, and surrounding the king and the Diet with ferocious soldiers, compelled them, by the most indecent menaces, to undo their glorious labour of love, and to restore the constitution as settled after the partition-treaty.

General rising.

On the 21st of April 1792, the Diet received the first notification from the king, of the inimical and unjust intentions of Russia. He informed them that, without the shadow of pretence, this power had determined to invade the territory of the republic with an army of sixty thousand men. This formidable force, commanded by Generals Soltikof, Michelson, and Kosakowski, was afterwards to be supported by a corps of twenty thousand, and by the troops then acting in Moldavia, amounting to seventy thousand. The king, however, professed that he was not discouraged; and he declared his readiness to put himself at the head of the national troops, and to terminate his existence in a glorious contest for the liberties of his country. Then, and not before, the Diet decreed the organization of the army, and its augmentation to a hundred thousand. The king and the council of inspection were invested with unlimited authority in everything that regarded the defence of the kingdom. Magazines were ordered to be constructed when it was too late, and quarters to be provided for the army. The Diet and the nation rose as one man to maintain their independence. All private animosities were obliterated, all private interests were sacrificed; the greatest encouragements were held forth to volunteers to enroll themselves under the national standard; and it was unanimously decreed by the Diet that all private losses should be compensated out of the public treasury.

Russian declaration.

On the 18th of May the Russian ambassador delivered a declaration worthy of such a cause. It asserted that this wanton invasion, which was evidently against the sense of almost every individual Pole, was intended solely for the good of the republic. It censured the precipitancy with which the new constitution had been adopted, and ascribed the ready consent of the Diet to the influence of the mob of Warsaw. It represented the constitution as a violation of the principles on which the Polish republic was founded; complained of the licentiousness with which the sacred name of the empress was treated in some speeches of the members; and concluded by professing, that on these accounts, and in behalf of the emigrant Poles, her imperial majesty had ordered her troops to enter the territories of the republic. At the moment when this declaration was delivered to the Diet, the Russian troops, accompanied by Counts Potocki, Rzewuski, Branicki, and a few Polish renegades, appeared upon the frontiers, and, before the close of the month, entered the territories of the republic in several columns.

Spirit of the nobles.

The spirit manifested by the nobility was truly honourable to that body. Some of them delivered in their plate to the mint. Prince Radzivil engaged voluntarily to furnish ten thousand stand of arms, and another noble offered to provide a train of artillery. The courage of the new and hastily embodied soldiers corresponded with the patriotism of their chiefs. Prince Poniatowski, nephew of the king, was appointed commander-in-chief; and though his force was greatly inferior to the enemy, it must be confessed that he made a noble stand.

Conduct o the court of Berlin.

The perfidy, the meanness, and the duplicity manifested by Prussia on this occasion is probably without a parallel in history. By the treaty of defensive alliance, solemnly contracted between the republic of Poland and the king of Prussia, and ratified on the 23d of April 1790, it is expressly stipulated, that the contracting parties shall do all in their power to guarantee and preserve to each other reciprocally the whole of the territories which they respectively possess; that, in case of menace or invasion from any foreign power, they shall assist each other with their whole force, if necessary; and that if any foreign power whatever should presume to interfere in the internal affairs of Poland, his Prussian majesty would consider this as a case falling within the meaning of the alliance, and assist the republic according to the tenor of the above article, that is, with his whole force. What, then, was the pretext for violating this treaty? It was this, that the empress of Russia had shown a decided opposition to the order of things established in Poland on the third of May 1791, and was provoked by Poland presuming to put herself into a posture of defence. It is ascertained, however, by the most authentic documents, that nothing was effected on the 3d of May 1791, to which Prussia had not previously assented, and which she did not afterwards sanction; and that Prussia, according to the assertion of her own king, did not intimate a single doubt respecting the revolution till several months after it had taken place; in short, to use the king's own words as explanatory of his double politics, "not till the general tranquillity of Europe permitted him to explain himself." Instead, therefore, of assisting Poland, Prussia insultingly recommended to Poland to retrace her steps; in which case, she said that she would be ready to attempt an accommodation in her favour. But this attempt was never made, and probably never intended; for the empress pursued her measures without opposition.

War with Russia.

The duchy of Lithuania was the great scene of action in the beginning of the war. But the Russians had made little progress before the middle of the month of June. On the 10th of that month, General Judycki, who commanded a detachment of the Polish troops between Mire and Swierzna, was attacked by the Russians; but, after a combat of some hours, he obliged them to retire with the loss of five hundred men dead on the field. The general was desirous of profiting by this advantage, by pursuing the enemy, but was prevented by a violent fall of rain. On the succeeding day, the Russians rallied again to the attack; and it then too fatally appeared that the Poles, being young and undisciplined, were unable to contend with an inferior force against experienced troops and able generals. By a masterly manœuvre, the Russians contrived to surround their antagonists, at a moment when the Polish general supposed that he had obliged the enemy to retreat; and though the field was contested with the utmost valour by the troops of the republic, they were at length compelled to give way, and to retire towards Nieswiesz.

On the 14th another engagement took place near Lubar, on the banks of the river Sluez, between a detachment of the Russian grand army and a party of Polish cavalry despatched by Prince Joseph Poniatowski to intercept the enemy. The patriotic bravery of the Poles proved victorious in this contest; but upon reconnoitring the force of the enemy, the prince found himself incapable of making a successful stand against such superior numbers. He, therefore, gave orders to strike the camp at Lubar, and commenced a precipitate retreat. During their march, the Polish rear was harassed by a body of about four thousand Russians. The Polish army next directed its course towards Zielime, where meeting, on the 17th, with a reinforcement from Zaslow, it halted to give battle to the enemy. The Russians were upwards of seventeen thousand strong, with twenty-four pieces of cannon, and the force of the republic much inferior. After a furious contest, from seven in the morning till five in the afternoon, the Russians were at length obliged to retreat, and leave the field of battle in possession of the patriots.

Notwithstanding these exertions, the Poles were obliged gradually to retire before their numerous and disciplined enemies. Nieswiesz, Wilna, Minsk, and several other places of less consequence, fell one after another into their hands. On a truce being proposed to the Russian general Koehowski, the proposal was haughtily rejected; whilst the desertion of vice-brigadier Rudnicki and some others, who preferred dishonour to personal danger, proclaimed a tottering cause. The progress of the armies of Catharine was marked with devastation and cruelty; whilst such was the aversion of the people, both to the cause and the manner of conducting it, that, as they approached, the country all around became a wilderness, where scarcely a human being was to be seen.

In the mean time, a series of petty defeats, to which the inexperience of the commanders, and the intemperate valour of newly-raised troops, appear to have greatly contributed, served at once to distress and dispirit the defenders of their country. Prince Poniatowski continued to retreat; and on the 17th of July, his rear being attacked by a very superior force, it suffered a considerable loss, although the skill and the courage of General Kosciuszko enabled him to make a most respectable defence. On the 18th, a general engagement took place between the two armies. The Russian line extended opposite Dubienka, along the river Bug, as far as Opalin; and the principal column, consisting of fourteen thousand men, was chiefly directed against the division of General Kosciuszko, which consisted only of five thousand men. After a most vigorous resistance, in which the Russians lost upwards of four thousand men, the troops of the republic were compelled to give way before the superior numbers of the enemy, and to retire further into the country.

The king proposes submission.

This unequal contest was at last prematurely terminated. The king, whose benevolent intentions were, perhaps, overpowered by his mental imbecility, and whose age and infirmities, probably, rendered him unequal to the difficulties and dangers which must attend a protracted war, instead of putting himself at the head of his army, determined at once to surrender at discretion. On the 23d of July he summoned a council of all the deputies at that moment in Warsaw, and laid before them the last despatches from the empress, which insisted upon total and unreserved submission. He pointed out the danger of a dismemberment of the republic, should they delay to throw themselves upon the clemency of the empress, and to entreat her protection. He also mentioned the fatal union of Austria and Prussia with Russia, and the disgraceful supineness manifested by every other court in Europe. Four citizens, the intrepid Malachowski, and the Princes Sapieha, Radzivil, and Soltan, vehemently protested against these dastardly proceedings; and the following evening a company of gentlemen from the different provinces attended for the same purpose. The assembly immediately waited upon these four distinguished patriots, and returned them their acknowledgements for the spirit and firmness with which they had resisted the usurpations of despotism. The submission of the king to the designs of Russia was no sooner made known than Poland was bereft of all her best and most respectable citizens. Malachowski, as marshal of the Diet, and Prince Sapieha, grand marshal of Lithuania, entered on the journals of the Diet strong protests against these proceedings, and declared solemnly that the Diet legally assembled in 1788 was not dissolved.

The former constitution restored

On the second of August a confederation was formed at Warsaw, of which the renegade Potocki was chosen marshal. The acts of this confederation were evidently the despotic dictates of Russia, and were solely calculated to restore the ancient abuses, and to place the country under the aggravated oppression of a foreign yoke. It is remarkable, however, that at the very moment when Poland was surrendering its liberties to its despotic invaders, the generous sympathy of Great Britain was evinced by a liberal subscription, supported by the most respectable characters in the nation, of every party and of every sect, for the purpose of assisting the king and the republic to maintain their independence; and though the benevolent design was frustrated, yet the fact remains on record as a noble testimony of the spirit by which Britons are animated in the cause of freedom, of the indignation which fills every heart in this empire at the commission of injustice, and of the liberality with which all are disposed to assist those who suffer from the oppression of tyrants.

Part of the Polish territory seized

Not satisfied with restoring the old wretched constitution, the empress of Russia seized upon part of the territory which, at the last partition, she and her coadjutors had left to the republic; and her ambassador entering into the Diet with a crowd of armed men, compelled the king and that assembly to grant the form of legality to her usurpations. The nation, however, did not submit.

Gallant effort of Kosciuszko.

In February 1794 General Kosciuszko appeared in the neighbourhood of Cracow with a small force of armed peasants. He beat some detachments of Russians and Prussians, compelled them to evacuate Cracow, and there proclaimed the constitution of 1791. Everywhere the people and the nobles flew to arms. The Russians, who occupied Warsaw with fifteen thousand men, began to seize suspected persons, and demanded possession of the arsenal. But at that moment the news arrived of a defeat sustained by a corps of six thousand Russians, with the loss of a thousand killed, and their general, Woronzow, made prisoner. Encouraged by this event, the people rose on the garrison, and after forty-eight hours' hard fighting, drove them out, with the loss of six thousand killed, three thousand prisoners, and fifty pieces of cannon. The whole country was now in arms. Russia and Prussia, however, sent a hundred and ten thousand men into Poland. Kosciuszko, pressed by superior forces, made an able retreat upon Warsaw. The king of Prussia, after besieging the city during three months, was compelled to retire towards his own territories with the loss of twenty thousand men. Here he was harassed for some time by Madalinsky with a small corps of cavalry. Kosciuszko, relieved from the Prussians, marched against the new Russian armies, which, during the siege of Warsaw, had reconquered Lithuania and Volhynia. But the battle of Noezylac, on the 10th of October 1794, in which the Poles fought with heroic resolution against overpowering numbers, proved fatal to their unhappy country. Kosciuszko was made prisoner and carried to St Petersburg, where he languished in a dungeon until the death of Catharine. The

Russians, after this event, united their forces and marched upon Warsaw, where the Poles had named Wawrzecky general-in-chief. He had only ten thousand men to oppose to fifty thousand, but an obstinate resistance was nevertheless offered. The last remains of the national army were concentrated at Praga, on the right bank of the Vistula, immediately opposite Warsaw; but they were soon broken by the furious charges of the Russian general Suwarof, who gratified his natural cruelty by the most frightful carnage. The fate of Poland was now decided. After the capture of Praga, Warsaw capitulated. Nine thousand Poles fell in the fight; thirty thousand persons of all ages and either sex were destroyed in cold blood; and thirty thousand more, who still refused to submit, were suffered to leave the place, and afterwards hunted down by the soldiery. The most distinguished chiefs were carried away to distant provinces; and the wretched king was sent to Russia, where he ended his days in 1798.

Treaty of partition.

The two powers were proceeding to divide the remaining provinces between them, when Austria interfered, and declared that she would not permit the destruction of Poland unless she received a share. At that moment it was not thought prudent to raise up a new enemy; and Austria obtained a considerable addition of territory, without having struck a blow or expended a florin. The negotiation continued till 1795, when the definitive treaty of partition was signed, which closed a series of transactions unparalleled for perfidy, cruelty, and infamy in the history of Europe. Austria received Cracow, with the country lying between the Pilitsa, the Vistula, and the Bug. Prussia had the capital, with the territory as far as the Niemen. The lion's share, as usual, fell to Russia. After an existence of near ten centuries, the republic was thus erazed from the list of nations. No people on earth, perhaps, have ever shown so much personal bravery as the Poles. Their whole history indeed is full of wonderful victories. But with such a vicious frame of society as we have already described, the most chivalrous valour, and the most splendid military successes, could avail nothing. It could not enforce obedience to the laws, nor maintain domestic tranquillity; it could not preserve the proud nobles from dissipation, nor prevent them from receiving bribes to repair their shattered fortunes; it could not restrain the powers which lavished the means of corruption from interfering in the affairs of the kingdom; it could not dissolve the union of these powers with the malcontents at home; it could not infuse vigour into a government corrupted by foreign gold, nor avert the invasion of foreign armies to support the factious and rebellious; it could not, while divided against itself, uphold the independence of the nations against foreign and domestic treason; in a word, it could not effect impossibilities, and though it might dazzle by its glory, it could not counteract those slow but sure-working causes which determined the inevitable doom of Poland.

This great crime committed with impunity.

The extinction of the Polish republic afforded ample scope for political declamation. The tribunes of France, the parliament of England, and the press of both countries, resounded with eloquent invectives against the perfidy and violence of the partitioning powers, and general sympathy was awakened in favour of a people whose great actions were entitled to admiration, whilst their misfortunes moved our commiseration. But complete impunity awaited the despoilers of that unhappy country. The troubled state of affairs throughout Europe did not permit any power to interfere in behalf of the oppressed. A selfish and shortsighted policy paralysed every arm, and chilled every heart. The great cause of public justice and national independence found no advocates, whilst the attention of all was absorbed in a narrow and confined struggle for their own preservation. The three potentates were therefore enabled to perfect their common wickedness without the slightest hindrance; to repress the indignant efforts of the sufferers; to crowd their prisons with the best and bravest, who had either distinguished themselves in the recent struggle, or had ventured to express dissatisfaction with the new state of things; to disarm the inhabitants of the great towns, and to establish formidable garrisons of foreign troops, who were ready to crush the very first attempt at insurrection.

Compact of the Poles with Franc

The Poles had no longer a country to fight for or defend; they had lost everything but honour and the feeling of revenge. They carried all they had left, namely, their valour, into the market, and soon entered into a compact with republican France. At Cracow was formed a secret confederation, the members of which offered to the French Directory to sacrifice their lives at the first call of the republic. Nor was this a vain or futile offer. Hundreds of the warlike nobles, escaping from bondage at home, proceeded to Venice or to Paris, and under Dombrowski, their brave leader, were formed Polish legions, in aid of the newly-created Italian republics, and ready to act wherever their services might be required. Their pay and subsistence were to be furnished by the Italian states; they preserved their national arms and dress; and, taking as their motto that all freemen are brothers, they fully participated in that daring spirit which then shook Europe to its centre. That they were allured by the prospect which had been held out to them of their country's restoration, is well known; and if their faith was rather the measure of their own ardent hopes than the result of any rational or well-grounded conviction, it may at least be pleaded in their favour, that the unfortunate are naturally credulous, and that a true Pole can never eradicate from his heart the belief that all his fondest wishes will one day be gratified. But be this as it may, their martial prowess contributed essentially to the success of the republican cause. Their number was increased by fresh recruits, which more than compensated the casualties of the field; their brilliant valour shone resplendent in every battle where they were engaged; patriotism and revenge alike nerved their arms for the conflict. But they soon had occasion to distrust the fair professions of the republican hero. When anxious, by his means, to preserve an entrance to the congress of Rastadt for a representative of Poland, they were coolly told that the hearts of all friends of liberty were for the brave Poles, but that time and destiny alone could restore them as a nation. Still they did not despair. If the day of regeneration was deferred, might it not yet arrive, perhaps at no distant period, when a more favourable conjuncture of circumstances would render it impossible for the French government any longer to evade urging their claims? Where justice, and freedom, and independence were concerned, they could not believe that fortune would always frown on their cause, or that iniquity in high places would secure for itself an immunity from all retribution.

The natur of their connectio with Fran

The connection of the Polish legions with France exhibits the same unvaried picture of gallant services performed, and of hope deferred. Their loyalty was sustained by a strong passion for military fame; to them the tent was their home, the battle-field their country; and though they suffered severely, particularly during the absence of Napoleon in Egypt, yet they repaired their losses with astonishing promptitude, and, in the year 1801, amounted to fifteen thousand. But their blood flowed in vain. In every treaty which their valour had been instrumental in winning, their services were overlooked, and their country was forgotten. In Italy and on the Danube, Generals Dombrowski and Kniaziewicz, with their legions, represented the Polish nation, and maintained its ancient renown in arms, though to little purpose, as far as regarded their country. For five years, their bravery proved unavailing, in as far as concerned the main object for which they had fought and bled.

But with the year 1806 new hopes began to revive. The

Campaigns of 1806 and 1807.

brilliant campaign of that year, the simultaneous victories of Jena and Auerstadt, and the advance of the French army into Poland, seemed an earnest of future success, a sure pledge of approaching restoration. A general burst of enthusiasm followed. Polish regiments were organized with amazing rapidity, and the approach of Kosciuszko was proclaimed. On the 27th of November, Napoleon entered Posen in triumph; in December Warsaw received him with not less enthusiasm; a commission of government was immediately organized; and as his purpose was announced, his armies were recruited by thousands of the best troops in Europe. The battle of Eylau had been a mere butchery, unproductive of any result; but on the field at Friedland, Dombrowski had given signal proofs of his own talents and the valour of the heroes he commanded; and the opening of the negotiations at Tilsit was hailed by the Poles as the dawning of a bright and auspicious futurity. But the result proved that they had been far too sanguine in their anticipations. Napoleon in effect, though not probably in intention, betrayed them, and at the same time lost the opportunity of erecting a powerful barrier against the encroachments of Russia. Instead of restoring the kingdom of Poland in something like its ancient power and dimensions, he contented himself with forming a small portion of his conquests into the grand duchy of Warsaw, which he united with Saxony.

Grand duchy of Warsaw.

The duchy of Warsaw, thus established, consisted of the departments of Posen, Kalisch, Plock, Warsaw, Lomza, and Bydgoszez, with a population somewhat exceeding two millions. With this shred and mockery of a country the Poles were highly dissatisfied. They had been taught to expect that the ancient kingdom, if not Lithuania itself, would become irrevocably their own; and their mortification may therefore be conceived on finding that Prussia was to retain several palatinates, that Austria was guaranteed in her Polish possessions, that the provinces east of the Bug were to remain in the power of Russia, and that a considerable portion of the ancient republic west of that river, as far as the department of Bialystok, was ceded in perpetual sovereignty to the czar. Still the establishment of this duchy was probably intended as a point of departure in a new order of things, the ultimate term of which should be the restoration of Poland. By the new constitution, the Catholic religion was declared to be the religion of the state; but ample toleration, and even a community of civil rights, were allowed to the Dissidents. Serfage was abolished. In the king of Saxony, as grand duke of Warsaw, was vested the initiative of all bills or projects of law, the selection of senators, the nomination of the presidents of the dietines and the communal assemblies, and the appointment of all officers, civil and military; and the Code Napoleon was subsequently admitted as the basis of all judicial proceedings.

Reflections on this partial restoration.

Something had thus been gained, though the arrangement was far from being satisfactory; indeed, by some the peace of Tilsit was regarded as the grave of all their hopes. But the greater number, reposing an unexhausted faith in the justice of their cause, consoled themselves with the belief that eventually Poland would be recalled into political existence, and her independence re-established upon a sure foundation. Accordingly, in the war with Austria in 1809, they rendered the most important services to Napoleon. They conquered Gallicia, without the smallest aid from France; they reduced Cracow and the adjoining territory; they regained possession of the capital, which the archduke had temporarily occupied; and they humbled their enemies on every side. What their own arms had won, they conceived that they had a right to retain, and they regarded as inevitable the incorporation of these conquests with their infant state. But they were destined to be speedily undeceived. Not a foot of ground were they allowed to retain in Gallicia; and half of their other conquests between the capital and the Austrian frontier was wrested from their hands. Four departments were indeed incorporated with the grand duchy, viz. Cracow, Pradom, Lublin, and Siedlec. This acquisition, however, afforded but a small compensation for the sacrifices which had been made, the forcible loans which had been raised, the lives which had been wasted, and the misery which afflicted every class of the inhabitants. In truth, the policy pursued by Napoleon in regard to the Poles bore traces of doubt and hesitation; it was always timid, seldom judicious, never generous. He had not the courage to break through the entanglements of diplomacy, by which his inclinations were fettered, and to do a great act of retributive justice, leaving the consequences to Providence. He suffered himself to be paralyzed by conflicting pretensions, and sacrificed his own glory to conciliate powers who took the earliest opportunity of betraying him.

Invasion of Russia in 1812.

Nevertheless, when the war with Russia became inevitable, Napoleon, with the view of interesting the Poles in his behalf, had recourse to all the arts of popular excitement, and, strange as it may seem, with his usual success. The more reflecting portion, wearied out and disgusted, refused to be again deluded. "We are flattered when our services are required," said they. "Is Poland always to be fed on hope alone?" The mass, however, swayed by their feelings, listened to the representations of the imperial agents, and a great body of Poles took the field, whilst a general confederation of nobles declared the republic restored, the declaration being signed by the king of Saxony, in whose house the hereditary monarchy was to be vested. But the enthusiasm thus excited proved short-lived. The reply of Napoleon to the Polish deputation, which had followed him to Wilna, at once dissolved the spell, by showing the deputies that he had guaranteed to the Emperor Francis the integrity of the Austrian possessions in Poland. Illyria therefore could not, as they had hoped, be exchanged for Gallicia; and as to Lithuania, Napoleon not only considered, but even proclaimed it a hostile country, and treated it accordingly. But still the deputation erred egregiously in giving up all for lost. Everything depended on the success of the expedition, which would have enabled Napoleon to give the law to Austria as well as to Russia; and hence, when he exhorted them to fight for their own independence, and assured them that if all the palatinates combined they might reasonably expect to attain their object, he gave them advice which they would have done well to follow. At a moment so critical he could not give Austria a fair pretence for betraying him on the occurrence of the very first reverse; this would indeed have been the height of folly in one who had risked everything upon the issue of a single campaign. But, on the other hand, the success of the expedition must have proved highly beneficial to Poland; and, in chilling the national enthusiasm at this time, the deputation were innocently instrumental in inflicting the greatest evils on their unhappy country.

Results.

This is not the place to dwell on the unexampled disasters of the Russian campaign, which were greatly aggravated by the apathy of the Poles, and their refusal to co-operate in covering the retreat of the French army. The details are in the memory of all. The work of Napoleon was destroyed; the grand duchy of Warsaw ceased to exist; the king of Saxony was stripped at once of it and of a portion of his hereditary dominions; the allied, who were also the partitioning powers, again took possession of the towns which they had held previous to the invasion of Napoleon; and in this state matters remained, awaiting the meeting of a congress, which was to assemble to decide, amongst other things, the fate of this unhappy country.

Treaty of Paris. Poland.

The negotiations which commenced with the downfall of Napoleon, and were completed by the treaty of Paris in 1814, necessarily embraced the future condition of Poland, which, though then occupied by Russian troops, had from previous cession to France become a fit subject of arrangement, not for the eventual benefit of Russia alone, but for that of the whole European commonwealth. Public opinion, the interests of rulers, and the sympathies of the governed, were all in favour of the re-establishment of the kingdom in its ancient integrity; and the side of justice, policy, and humanity was powerfully advocated by France and England, whose ministers regarded the Polish question as one in comparison of which all others were of but secondary importance. But neither of these powers, nor both of them united, were in a situation to control the views of those interested in maintaining the state of things created by the successive dismemberments of Poland. France, exhausted by long wars, and now restricted within her ancient limits, had no longer a voice potential in the decision. Britain, with the right of remonstrance, which her minister freely exercised, was in no condition to brave two great military powers; and although Austria not only expressed a desire for Polish independence, but a readiness to surrender part of her Gallician provinces in order to endow the new kingdom, yet all this might have been easily counteracted by the predominant influence of Russia and Prussia. At that period, indeed, the Emperor Alexander displayed or affected a spirit of liberality, which appears to have owed its origin to various circumstances; but whether he was sincere or the contrary, "an accident," as Madame de Stael described him, or merely the impersonation of hypocrisy and perfidy, it was certain the genius of the Russian system would govern the ultimate determinations of his policy on a subject of so much importance to his empire.

The kingdom of Poland.

At this juncture, however, Napoleon escaped from Elba, and the whole question assumed a new phasis. In the common danger, Poland was scarcely remembered; and the czar, finding that his aid would be indispensable in the approaching contest, was enabled to insist on a measure which he had long contemplated, namely, the union of the grand duchy with Russia as a separate kingdom. The facility with which he carried his object proves the alarm that had been occasioned by the re-appearance of Napoleon, and the anxiety felt to adopt any measure calculated to prevent Polish partisanship from swelling the ranks of the invader. It was therefore decided that the grand duchy of Warsaw should be attached to the empire of Russia, under the name of the kingdom of Poland, and that it should be governed by separate institutions. "The duchy of Warsaw, with the exception of those provinces and districts which are otherwise disposed of, is united to Russia. It shall be irrecoverably bound to the Russian empire by its constitution, to be enjoyed by his majesty the emperor of all the Russias, his heirs and successors, for ever." Such are the expressions employed in an article relating to this point in the treaty of Vienna. The two sovereignties were united by the constitution alone, and not otherwise. This was the connecting link which bound them together. Austria and Prussia acceded to a similar arrangement, and also agreed to confer on their Polish subjects a national representation and national institutions. The concessions required by public opinion were made, and certain bases were solemnly sanctioned by the treaty of Vienna.

Bases of the union between Poland and Russia.

These were four in number. In the first place, Gallicia and the salt-mines of Wieliczka were restored to Austria. Secondly, the grand duchy of Posen, forming the western palatinates bordering on Silesia, and containing a population of about eight hundred thousand souls, was surrendered to Prussia; which power was also confirmed in the conquests made at the period of the first partition. Thirdly, the city and district of Cracow, about 445 English square miles in extent, and containing a population exceeding an hundred thousand souls, was formed into a free and independent republic, under the guarantee of the three powers. Fourthly, the remainder of ancient Poland, comprising the chief part of the recent grand duchy of Warsaw, with a population of about four millions, reverted to Russia, and was to form a kingdom irrecoverably bound, by the constitution which the czar had engaged to confer upon it, to the Russian empire. "The kingdom of Poland," said the Emperor Alexander, "shall be united to the empire of Russia by the title of its own constitution, on which I am desirous of founding the happiness of the country." Thus a part of Poland was re-established as a separate state, by the act of all the powers of Europe; and although the emperor of Russia was to be king of that state, still the independence and separate existence of the kingdom were not only recognised in the fullest manner, but at the same time solemnly guaranteed.

The constitutional charter.

The new kingdom of Poland was proclaimed on the 20th of June 1815, and on the 24th of December following a constitutional charter was granted to the Poles. The articles of this charter, by which Poland became united to Russia, were of so liberal a nature as to astonish all Europe. According to some, they prove that, at the time of their promulgation, Alexander was no enemy to liberal institutions. But the more probable supposition seems to be, that the earnest and loyal interposition of Great Britain and France, favoured by the declared disposition of Austria, and strengthened by the public opinion of Europe, had more effect on the mind of the czar than any presumed inclination towards liberal institutions, of which he afterwards became the most uncompromising opponent. The principle articles, which are now only matter of history, were as follow.

The principal articles of this charter.

The Catholic religion was declared to be the religion of the state; but all dissidents were placed on a footing of perfect equality as to civil rights, with the professors of the established faith. The liberty of the press was recognised in its fullest extent. It was provided that no subject could be arrested prior to judicial conviction. The inviolability of person and property was, in the strictest sense, guaranteed. All public business was to be transacted in the Polish language; and all offices, civil or military, were to be held by natives alone. The national representation was to be vested in two chambers, one of senators and another of deputies. The power of the crown was not greater than seemed necessary to give due weight to the executive. All kings of Poland were to be crowned at Warsaw, at the same time swearing to maintain the full observance of the charter; and during the absence of the sovereign for the time being, the chief authority was to be vested in a lieutenant and council of state. The great public departments of the state were to be presided over by responsible ministers. The legislative power was vested in the king and the two chambers; an ordinary Diet to be held every two years, and to sit thirty days, and an extraordinary Diet to be convened whenever this should be judged necessary by the king. No member of the Diet could be arrested during a session, except for great offences, and not even then without the concurrence of the assembly. The deliberations of the Diet extended to all projects submitted to it by the ministry, affecting the laws and the whole routine of internal administration. The deliberations of the Diet were to be public, except when committees were sitting. All projects of law originated with the council of state, and were laid before the chambers by order of the king; such projects, however, being previously examined by committees of both houses. In the case of all projects or bills, the majority of votes was to decide. The senators were to be nominated by the king, and to exercise their functions during life. The deputies, a hundred and twenty-eight in number, were seventy-seven for as many districts, and fifty-one for communes, or about double the number of senators. To become a member of the second or lower chamber, the qualifications were, citizenship, the age of thirty, possession of some portion of landed property however small, and the payment in annual contributions to the state of a hundred Polish florins. No public functionary was eligible to a seat without the consent of the head of his department. The nobles of each district were to meet in dietines for the purpose of electing one of their body to the general Diet, and returning two members to the palatine assemblies, all dietines being convoked by the king. The class of electors was numerous, comprising, first, all landowners, however small, who paid any contribution towards the support of the state; secondly, every manufacturer or shopkeeper possessing a capital of ten thousand florins; thirdly, all rectors and vicars; and, lastly, all artists or mechanics distinguished for talent. The electors required to be enrolled, and to have attained the age of twenty-one years. The tribunals were to be filled with judges partly nominated by the king, and partly elected by the palatinates; the former being appointed for life, and removeable only for misconduct, or judicial iniquity, in the discharge of their functions.

Remarks thereon.

Such were the principal provisions of the charter which was thus conferred on the Poles, and received by them as the first instalment of that restitution which they hoped would one day be made effectual and complete. Its greatest defect consisted in the incompetency of either chamber to propose laws, the initiative being confined exclusively to the executive, or the king and the council of state, and an effectual check thereby applied to legislative amelioration. Nor was any provision made in the charter for the establishment of trial by jury, an institution which, however suitable to our habits and modes of thinking, may not have been equally so to those of the Poles. But it is nevertheless certain that Alexander, on his return from witnessing the prosperity of this country, which he attributed in part to our judicial system, ordained the establishment of trial by jury throughout Poland within six months; being in this carried by mere impulse, without any regard to the fitness or unfitness of the institution to the wants, habits, and prejudices of the people amongst whom he proposed to naturalize it. It is not thus that national benefits are really conferred, or that new systems can ever be advantageously introduced.

Perfidy of Russia. Constantine.

From the re-establishment of the kingdom in 1815, until the year 1820, the affairs of Poland were conducted apparently in conformity with the constitution. The benefits of the government had to a certain extent disarmed the prejudices and antipathies of the people; the opposition to ministers in the lower chamber was comparatively trifling; the emperor's lieutenant, Count Zayonczek, a Pole, endeavoured to attach the Poles to his sway; and Alexander, congratulating himself on the liberal policy which he had adopted towards his new subjects, declared in full senate at Warsaw, that he only waited to try the effect of the free institutions he had given them, in order to extend those institutions over all the regions which Providence had placed under his sway. But all this fair promise proved hollow and deceptive. From the very first there had been perpetual breaches in the constitution; and after the Spanish revolution of 1820, followed as it speedily was by the establishment of the Holy Alliance, all disguise was thrown aside, and an attempt made to suppress entirely the spirit of national independence in Poland. Count Zayonczek was only nominally the king's lieutenant. The real power was invested in the Grand Duke Constantine, who held the appointment of commander-in-chief of the army. This personage, who played so conspicuous a part in the affairs of Poland, is deserving of notice, in consequence of the position in which he was placed. Although possessed of considerable talents, he was, in fact, an untamed tiger, giving way on all occasions to the most violent paroxysms of passion. He had a strong sense of the rights of his order, and held as nought the feelings of every other class. As soon, therefore, as he found that his brother was no longer the liberal patron of constitutional rights, he gave the most unrestrained license to his natural violence and caprice. The outrages ascribed to him display a mixture of ferocity, cruelty, and cowardice, altogether unparalleled. With him no right was respected, and no condition safe. Females were insulted, abused, sometimes kicked; shaving the heads of such women as displeased him was a common occurrence; and to this was added tarring and feathering, a favourite recreation of the commander-in-chief, whose delight it was to witness these barbarities. He kept in his employment a legion of spies; and the liberty or life of every man was at the mercy of a common informer. With him suspicion was a sufficient warrant to exclude the proof of innocence, and accusation led at once to conviction.

Political tyranny superadded to private oppression.

But whilst acts of private oppression were calling forth all that hatred of Russia which is the birthright of every Pole, political tyranny was superadded, as if it were desirable to concentrate upon one point the entire indignation of a brave and devoted people. The liberty of the press was abolished, and a censorship established, in violation of article sixteenth of the constitutional charter. This was effected by an ordinance dated the 31st of July 1819; and not long afterwards the patriotic association formed by General Dombrowski, who had modelled it almost after the recommendation of Alexander, was suppressed, and a military commission appointed, which tried and condemned civilians without any of the prescribed formalities. "What have we to hope," exclaimed Dombrowski; "what have we not to fear? This very day might we not tremble for the fate which may await us to-morrow?" Meanwhile, the secret police pursued its fatal career, and arbitrary arrests, followed by hidden condemnations, the banishment of many and the imprisonment of more, signalized its hateful activity. The university of Wilna was also visited with severity by the agents of this dreaded institution. Twenty of its students were seized, and subjected to different punishments. Nor were those of Warsaw treated with greater leniency. A state-prison was likewise erected in the capital, and its dungeons were soon crowded with inmates, victims of the execrable system adopted by the government. Nor were these the only grievances of which the people had reason to complain. Although the constitutional charter had provided that Russian troops, when required to pass through Poland, were to be maintained at the sole charge of the Russian treasury, yet for years they had been stationed at Warsaw, and paid by the inhabitants of the capital, whom they were employed to overawe. Further, independently of the violations of individual liberty, the difficulty of procuring passports, the misapplication of the revenue to other objects than those for which it had been raised (as the maintenance of the secret police), and the nomination of men as senators, without the necessary qualifications, or any other merit than that of being mere creatures of the government, were infractions of the charter as wanton as they were intended to be humiliating. But the worst of all yet remains to be told. In the dietines Russian money and influence were unblushingly employed to procure the return to the general Diet of such members only as were known to care less for the honour of their country than the advancement of their own fortunes. Instead of a Diet being held every two years, in accordance with article eighty-seventh of the charter, none was convoked from 1820 to 1825, and only one from the year 1825 until after the accession of Nicolas in 1829. Finally, an ordinance issued as early as 1825 had abolished the publication of the debates in the two chambers; and on one occasion, the most distinguished members of opposition were forcibly removed from Warsaw the night preceding the opening of the Diet. Add to all this the constant irritation produced by the ungovernable temper and consequent excesses of Constantine; the useless but vexatious manœuvres he introduced into the army; his rigorous mode of exercise, exceeding the ordinary measure of human strength and endurance; his overbearing manner towards the best and highest officers in the service; and, above all, that progressive increase in cruelty which a regimen of terror presupposes and almost necessitates: take these matters into consideration, along with all the other circumstances of grievous oppression which have already been stated as affecting the mass of the people, and it will easily be seen that it was vain to whisper peace, and that the grand duke was treasuring up to himself wrath against the day of wrath.

Universal discontent. Favourable moment for rising lost. Revolution of Paris, July 1830.

It has been matter of some surprise to foreigners that the Poles did not take advantage of the Russo-Turkish war to erect the standard of independence. The reverses experienced by the Russian army on the Danube in the campaign of 1828, were so great, that an insurrection in Poland at that critical and perilous moment would have had almost every chance in its favour. But at that period the plan of the Poles had evidently not been matured. That it was even so in November 1830 may reasonably be doubted. In fact, no preparations seem to have been made, and when the explosion actually took place, it was wholly unexpected by the leading patriots, who conceived that the propitious moment had not yet arrived. At the same time it must be confessed, that the French Revolution of July 1830 produced an almost electric effect on the whole Polish nation, and, by its daring character and its splendid success, disposed the initiated to anticipate the time for a general rising. Besides, it is generally believed that emissaries from Warsaw had held confidential meetings with the leaders of the Revolution of July, and were instigated to rouse their countrymen by the promise of immediate aid from the government of the citizen king; and that such aid was confidently relied on by the Polish patriots themselves, must be known to all who have conversed with those who acted a prominent part in the national insurrection, and seems to be further confirmed by the universal impression of the people. Two other circumstances also contributed to accelerate the catastrophe. The army began to entertain a notion, not altogether unfounded, that it was to be removed to the south of Europe, to assist in extirpating freedom in France and other countries; and that its place was to be supplied by a native Muscovite force. The students of the military school likewise found ample cause of apprehension in the previous arrest of several of their number, upon suspicion of being connected with secret associations, which had for their object to promote a general rising. The repugnance of the army to the service intended for them; the apprehensions of the students, who had everything to fear from the grand duke, should he try their companions by martial law, as he had threatened to do, and most probably meditated; the conviction that the whole populace of the capital were friendly to the project of an insurrection; the secret encouragement held out by France; the eagerness of the enterprising to court danger for its own sake; the number of those who had personal wrongs or insults to avenge; and, lastly, the presumed, or rather the certain, approbation of the free in all countries towards the insurrection itself, if not towards the time and the circumstances: all these, therefore, concurred to hasten the opening of the great tragedy, the enacting of which all Europe regarded with such deep and thrilling interest.

The first object of the actors in this enterprise was to seize the person of the grand duke, their most obnoxious enemy, and to detain him as a hostage for their own safety in the event of failure. The students of the military school were the voluntary leaders of the movement, which burst forth on the 29th of November 1830. Early in the evening of that day, several of them repaired to their barrack, in accordance with a preconcerted plan; and having addressed their comrades, summoned them to take up arms. The call thus made was instantly obeyed. On their way to the residence of Constantine, who had established himself at the palace of Belvedere, in the outskirts of the city, their number was increased by the students of the university, and the young men attending the public schools. Constantine had no troops about his residence, but at a short distance from it were the barracks of three regiments of Russian guards. The hour chosen for the attack was seven o'clock, and at that time the assailants proceeded to the bridge of Sobieski, where the main body posted themselves, whilst some of the most determined pressed forward to complete their object. They forced their way into the palace, where they were first opposed by the director of the police, Lubowidizki, who, on being wounded, took to flight. Next they encountered the Russian general, Gendre, a man obnoxious for his cruelties and crimes, who was killed in the act of resisting. Lastly, when on the point of reaching the bedchamber of the grand duke, whom the alarm had just awaked from his evening siesta, they were stopped by a valet, Kochanowski, who, closing a secret door, thus enabled his master to escape undressed through a window. Constantine fled to his guards, who instantly turned out. Disappointed in their prey, the devoted band rejoined their companions at the bridge of Sobieski, where they had been awaiting the result of the attack on the palace. On finding that their first object had failed, they now resolved to gain the city, and at once proclaim a general insurrection. Their retreat was opposed by the Russian guards, close to whose barracks it was necessary to pass. But such was the spirit which animated them, such were the skill and courage they displayed, that they killed three hundred of their opponents, and triumphantly effected their retreat. On reaching the city, they instantly liberated every state-prisoner, and were joined by the school of engineers and the students of the university. A party entered the only two theatres which were open, calling out, "Women, home; men, to arms." Both requisitions were instantaneously complied with. The arsenal was next forced, and in less than two hours from the first movement, so electrical was the cry of liberty, forty thousand men of all descriptions were in arms. The sappers and the fourth Polish regiment declared early in favour of the insurrection; and by eleven o'clock the remainder of the Polish troops in Warsaw, with the exception of two regiments of guards whom Constantine had forced along with him, espoused the popular cause, declaring that their children were too deeply compromised to be abandoned. Never perhaps was any popular movement more universal or more triumphant.

By the morning of the 30th of November the commotion had subsided, and the results could be calmly surveyed. Besides the troops of the line which had joined the patriots, nearly thirty thousand citizens had taken up arms, and now swelled their dense ranks. In twelve hours the revolution had been begun and completed. In vain did the grand duke, who lay without the walls, meditate the recovery of the intrenchments and fortifications. His isolated though desperate efforts to re-enter the city were repulsed with serious loss; and finding it hopeless to contend with the mass opposed to him, he not only desisted from all further attempts of the kind, but removed to a greater distance from the walls. In the excitement consequent on this extraordinary commotion, no one will be surprised to learn that, notwithstanding the regularity with which every part of it was conducted on the part of the principal actors, some excesses were committed. But these were neither many in number nor aggravated in character; and although some Russians lost their lives, as did also several Poles, who were known to have been on terms of intimacy with Constantine, yet these men courted their fate by recklessly intermingling amongst an excited population when their passions were inflamed by the heat of battle, the tumult of victory, and the feverish excitement of revolution.

The functionaries of the government having abandoned their posts, an administrative council was immediately formed to preside over the destinies of the new state. It consisted of men distinguished for their talents, their character, or their services, and numbered amongst its members Czartoryski, Radzivil, Niemcewicz, Chlopicki, Pac, Kochonowski, and Lelewel. But no good resulted from this heterogeneous assemblage of persons professing moderate and ultra opinions, or what may be called Whigs and Radicals. The former were not men made for revolutions, though in this instance they obtained the direction of the movement; and in the hope of accommodation, which from the first was desperate, they allowed the grand duke to retire under a convention, when they might have captured his entire army, and detained himself as a hostage. At first they evidently entertained no intention of throwing off their allegiance to the Czar. All their proclamations ran in his name, and their claims were confined to a due execution of the charter. On the part of the provisional government, however, this seems to have been the very excess of weakness. Men who engage in revolutions, if they hope or wish to succeed, should, when they draw the sword, throw away the scabbard. Besides, as nothing less than unconditional submission would gratify the Czar, it is obvious that negotiation was at once a waste of time, and a confession of indecision. The next blunder of the council was in the opposite direction. As their patriotism appears to have risen with their success, they at length insisted on the incorporation of Lithuania, and the other Polish provinces subject to Russia, with the kingdom; and, as if this had not been enough, they some months afterwards declared the throne vacant, an act which, upon their own principles, was equally rash and impolitic. But, what was worst of all, they lost precious time. The force of the first impulsion was wasted. The great and sudden outburst of national enthusiasm was allowed to exhaust itself. Russia had been braved at a time when all her energies might be concentrated to enforce submission; when neither foreign war nor domestic disturbance distracted her councils or divided her means; yet, so far from profiting by the only advantage resulting from the wild improvisation so rapidly nationalized, the provisional government acted as if their sole object had been to forego the chances which the national movement had, in the first instance, accumulated in their favour.

But all these errors were nobly redeemed. When it appeared that negotiation was vain, and that nothing but unconditional submission would satisfy the Czar, they gallantly prepared themselves for the unequal struggle. Their plans were evidently not matured. Neither from Lithuania, nor from any of the other Polish provinces incorporated with Russia, did they receive the aid on which they had relied; so that the honours of the first campaign were exclusively their own. Their efforts were stupendous, and their bravery was worthy the age of Boleslas and Sobieski. The laurels which Diebitsch Zabalkanski had reaped in his campaign against the Turks, protected by mountains and fortresses, were blighted and withered in the plains of Poland. On the 25th of February 1831 his dense masses, first brought into contact with the patriotic forces at Grochow, recoiled from the shock, after one of the most unequal and sanguinary conflicts of modern times. March was illustrated by the victories of Dembewielki and Wawr; and in May was fought the celebrated battle of Ostrolenka, where, after performing prodigies of valour, the Polish army retired from the field, unpursued, towards Modlin. In the meantime, Diebitsch had perished, the victim of disease, chagrin, and fatigue. Paskewitsch, distinguished by his Armenian campaigns, succeeded, and, following the example of his predecessor Suwarof, concentrated all his means for an attack on the capital. On the 5th, 6th, and 7th of September was fought the ever-memorable battle of Warsaw, which ended in the defeat of the patriot forces and the loss of that city, after a struggle unparalleled in history. This blow proved decisive. European interference had been hoped for, but in vain; the faith of treaties had been appealed to without effect; the interests and the sympathies of the civilized nations of the West and the South had been invoked to no purpose. A powerful force still remained, and, for a time at least, a partisan warfare might have been carried on; but thus abandoned to its own resources, Poland must at last have yielded to her gigantic antagonist. That country had no mountain fastnesses, where her children, when overpowered by numbers, might take shelter; it had no fortresses capable of arresting and breaking the force of her assailants. Nothing could have saved her but a prompt and active interposition, founded on the treaty of Vienna; and such was the situation of France and England at the time that neither judged it safe or expedient to interfere otherwise than by remonstrance.

The Poles submitted. With reluctance they laid down those arms which they had taken up in the hope of re-conquering their national independence, and which they had so gloriously employed in many a hard-fought field. But all former experience of Muscovite vengeance could scarcely have prepared them for the miseries which have since been accumulated, in new and fearful forms, on their unhappy country. To say nothing of proscription and confiscation, her plains have been covered with ruins, her resources exhausted, her industry and commerce destroyed; abundance has given place to wretchedness and want; she has no longer a name or a place amongst the nations; her language, her literature, and her history cannot any more be publicly taught in her schools; and every effort has been made to destroy that sentiment of nationality which is part of the inheritance of every Pole. And all this has been done in the face of the public guarantee of the powers of Europe, if not without remonstrance, at least without any effectual opposition.

Cracow. The history of the little republic of Cracow forms an appropriate sequel to that of the unhappy kingdom of Poland. That small state, created by the treaty of Vienna, and having its independence guaranteed by the same general compact, enjoyed the constitution which had been conferred on it until the year 1846, when it was seized upon by Austria, Russia, and Prussia; and by decree of 9th November its freedom was abolished, and it was annexed to Austria. (See CRACOW.) A greater outrage against every principle of public law or public faith was never probably perpetrated. It was an act of naked despotism, done in defiance of the other powers of Europe, and in open contempt of the most sacred principles of public law and public justice. Soon afterwards the kingdom of Poland was incorporated with Russia, and made a Russian province; and the history of Poland becomes a part of the history of the countries with which it has been united. (See RUSSIA, PRUSSIA, and AUSTRIA.)

Commerce. In former times the commerce of Poland was very considerable; the natural resources of the country and liberal commercial regulations opened a wide field for the activity and enterprise of foreign merchants. During the fourteenth, fifteenth, and sixteenth centuries, Poland not only carried on a lucrative commerce with the Levant, the Black Sea, and the Mediterranean, and maintained a commercial intercourse with the Italian republics, particularly Venice, but she also exported her corn and other raw materials to the western countries of Europe, especially Holland, Sweden, and Denmark, and formed an entrepôt of oriental merchandise for the northern part of Germany and the countries adjoining. Owing to their commercial activity, Cracow and Dantzic were at an early period admitted into the Hanseatic League.

Besides wood, flax, tallow, and some other products, corn has always been the principal article of export. According to Cellarius, who wrote in the sixteenth century, the amount of corn exported in one year was 10,950,000 korzec, or 4,380,000 English quarters. Opalinski, a writer of the seventeenth century, states that in his time Dantzic alone received from the interior of the country more than 6,000,000 korzec, or 2,400,000 English quarters, of different kinds of grain for exportation. The importation of foreign produce was of course proportioned to the exportation of home produce; and it was abundantly supplied to Poland both by national and foreign bottoms. Holland and Venice were extensively engaged in trade with this country. But with the political misfortunes of Poland its commercial importance declined; and its destruction has been completed in consequence of the system of monopoly pursued by the governments of Russia, Prussia, and Austria. In that part of Poland which is under the dominion of Russia, the consumption of every article of foreign produce is strictly prohibited, and every branch of industry is discouraged; whilst the governments of Austria and Prussia overwhelm their Polish subjects with disproportionate taxes, in the hope of thereby retaining them in more complete subjection. The consequence is, that the farmers have no motive or interest to produce more grain than they require for their own consumption; and hence, whenever any unforeseen contingency occurs, a famine must ensue, as has actually happened in some parts of Volhynia, Podolia, and the Ukraine; countries the soil of which is perhaps the most fertile of any in Europe.

Manufactures.

Poland never was a great manufacturing country. Her natural resources consisted in the produce of her soil, and her commerce in exchanging these for the cheaper and superior manufactures of other countries. With more than 80,000 square miles of fine wood; with the richest mines of salt Europe possesses at Bochnia and Wieliczka; with the fertile plains of the Ukraine, Podolia, Volhynia, and Landomierz; with the flax of Samogitia (so much employed in the English manufactures), the wool of Great Poland imported into Saxony, fine cattle and horses, abundance of tallow and other products; Poland possessed resources which, under a good government, might have made her, not indeed a manufacturing, but certainly one of the most commercial nations of Europe.

Literature.

Before the introduction of Christianity in the tenth century, the Polish language could boast of numerous traditional tales, warlike songs, and pastoral poems, which have been collected by Wodrich, and show that this language, having already attained to some degree of perfection, had consequently taken the lead of almost all the other Sclavonic tongues. It is no doubt true that the introduction of Christianity at first retarded the natural improvement of the language, by an admixture of foreign terms; but it enlarged and purified the ideas of Polish writers, and opened a new and attractive field for their talents and genius. It may appear surprising to some that, from the tenth till the end of the sixteenth century, Poland should have produced such a number of writers in the native idiom and in Latin; especially considering the continual wars in which she was engaged for the defence of her frontiers. But the wonder will cease when it is known that schools and colleges were then thrown open to every one; that education was eagerly sought after and freely imparted; that the order of St Benedict, assisted by other religious communities, devoted their whole time and attention to the gratuitous education of every class, implanting in all a love of science and literature, a taste for the arts, a knowledge of the classics, and an affection for the Muses; and that, under these same orders, the youth of the country were, both by precept and example, trained up to the practice, and excited to aspire to everything that was liberal, generous, and manly. Hence, prior to the foundation of the university of Cracow, which took place during the reign of Casimir the Great, in 1347, and preceded that of the universities of Prague, Vienna, and Leipsic, Poland possessed several historians and other learned men, whose writings still survive to attest the early cultivation of literature in that country.

Amongst these, the first place is due to the chroniclers. Gallus wrote his Chronicle of Poland between 1110 and 1135. Matthias Choleva, Bishop of Cracow, who wrote a Chronicle of Poland, died in 1165. Kadlubek Vincent, born at Cracow in 1160, enjoyed the favour of Casimir surnamed the Just, and officiated as tutor to Lesko the Fair. He wrote his Chronicle under the title of *Historia Polonica*, which was first published in 1612. Godislas Reszko, dean of Cracow, composed Annals of Great Poland. Martinus Polonus is known by his numerous writings, and particularly by his Chronicles of the Popes and Emperor. He died at Bologna in 1278. To this period also belong several men of science. Amongst these may be mentioned Octavian Wolener of Cracow, an architect who, a little before 1044, was invited to Vienna to erect the church now called St Stephen's. Ciolek, in Latin *Vitellio*, a native of Cracow, was celebrated as a naturalist and mathematician. He lived in the middle of the thirteenth century, and was considered as having contributed to improve and extend the science of optics. His works were printed for the first time at Nuremberg in 1533, under the title of *Vitellionis Perspectivæ libri decem.*

But whilst the intellectual superiority of Poland at this period was owing to her frequent and direct intercourse with Italy, it is to be observed that after the foundation of the university of Cracow, about the middle of the fourteenth century, she herself became the centre and source of civilization to the neighbouring nations. From this time Hungarians, Bohemians, Germans, Swedes, and Danes, who formerly used to repair to Italy for study, resorted almost exclusively to the university of Cracow. Of those who added celebrity to the university, there were some whose reputation was not confined to their own country. George of Sanok, born about 1400 and died in 1477, was first professor of moral philosophy in the university of Cracow, and afterwards archbishop of Leopol. His biography was written by Buonacorsi, surnamed Callimachus, a celebrated Italian philosopher. John of Glogau, born in 1440 and died in 1477, was also a professor in the university of Cracow, and left numerous manuscripts on different subjects, but mostly on the Aristotelian philosophy, several of which were afterwards published. Dlugosz, in Latin *Dlugossius*, born in 1415 and died in 1480, was a statesman and historian. As great treasurer of Poland, he, on many occasions, rendered important services to his native country; he also protected science, established hospitals, and founded an exhibition or bursary in the university of Cracow. Of his numerous writings, the most important is his *History of Poland.* Brudzewski, born in 1445 and died in 1497, studied at Cracow, and afterwards became professor of mathematics in that university, where he had the distinction of being the master of Copernicus. He left several works, the principal of which treat of astronomical subjects and the construction of the astrolabe. Nicolas Copernik, called in Latin *Copernicus*, born in 1473 and died in 1543, studied at Cracow, and by divining, through the mists of error rendered venerable by time, the true system of the world, established for himself a name which will live whilst sun and moon endure. Martin of Olkusz, the school-fellow and friend of Copernicus, died in the year 1530.

These men, however, with all their individual merits, were only the precursors or harbingers of a period of higher excellence and greater refinement. Free at home and powerful abroad, Poland during the sixteenth century occupied a distinguished place amongst the states of Europe; and the period of her political glory was also the golden age of her literature. Amongst the poets of this period, the first place belongs to John Kochanowski, born in 1530 and died in 1584, who is justly regarded as the father of Polish literature. He was the author of works both lyrical and dramatic, and translated Anacreon, Horace, some parts of the *Iliad*, and also the Psalms of David, which are remarkable for purity and vigour of style. Rey of Naglowice also wrote several works in verse and prose; whilst Peter Kochanowski left translations of Tasso's *Gerusalemme Liberata*, and Ariosto's *Orlando Furioso*, which were printed at Cracow in the year 1618. Miaskowski, Sarzynski, Rybinski, Grochowski, and Klonowitz, were likewise eminent as poets. As prose writers, may be mentioned Michowita, who wrote several important works, particularly on Polish history; Kromer, the son of a peasant, who by his talents obtained the highest ecclesiastical dignity in Poland (that of Prince-Bishop of Warmia), and left important works on the history of his country; Bieliski, who wrote on subjects of moral philosophy and history; Gornicki, an eminent writer on politics and history, and whose style is remarkable for its purity; Stryjkowski, a poet and historian; and Orzechowski, an apostate priest, but a distinguished writer and speaker, who, by his defence of the principles of the Dissidents, attracted the notice of Pope Julius III., with whom he maintained a long and animated controversy.

This period also produced several men distinguished in law, ethics, mathematics, and astronomy, the natural sciences, medicine, and agriculture. Amongst the lawyers and jurisconsults may be mentioned Herbert, secretary of Sigismund Augustus, who published a collection of statutes and privileges; Malecki, who wrote a book entitled *The Lawful Marriage of Bishops, Priests, and Monks;* Groicki, a civilian of eminence, the author of a work on the statute law of Magdeburg; besides Ianuszewski, Lazarowitz, and Smiglecki. In ethics, Rey, Koszucki, and particularly Petrycy, distinguished themselves, though in different degrees. Petrycy translated the *Ethics* of Aristotle, and also the *Policy* of the same author, which he published at Cracow in 1618, along with his own commentaries. In mathematics and astronomy, Poland could boast some of the most distinguished men of the age; but as most of them published their works in Latin, it is only necessary to mention here those who wrote in Polish. These were Klos, author of a treatise on arithmetic, published at Cracow in 1538; Grzebski, professor in the university of Cracow, whose works on geometry were published in 1656; and the astronomers Latos, Rosciszewski, Zebrowski, and Bernat. Nor were the cultivators of the natural sciences either few in number or inferior in zeal and knowledge. Amongst the more eminent may be mentioned Spiezynski, who wrote several works on botany, published at Cracow; Martin of Urzadow; Falimierz Syrenski, professor of medicine in Cracow, whose work on the properties and uses of plants, published after his death, is highly esteemed; Peter of Kobylny, Andrew Glader, Valenti of Lublin, Oleszko, and Umiastowski, skilful physicians, who published important works on different maladies; Trzecieski, author of several works on agriculture and husbandry published at Cracow in 1540 and 1571; and Dubrawski, whose work on fishes, published in 1600, is still considered a work of great merit. There were also during this period several writers on the art of war, amongst whom may be mentioned Strubiez, Paprocki, and Cielecki.

This, the golden age of Polish literature, continued from the middle of the fifteenth until the commencement of the seventeenth century. But from the reign of Stephen Batory, in 1586, we may date the temporary decline of Polish literature and the corruption of the Polish language. During the seventeenth century the introduction of the Latin language into official transactions, and the great political crisis which Poland had to undergo, obstructed the tendency of the national literature, and directed the energies of the Poles towards one great object, namely, the preservation of their political existence. Amidst growing internal disorder, at once the cause and the effect of national calamity, the peaceful pursuits of science were neglected; and under the two princes of the houses of Saxony, Augustus I. and his son Augustus II., Poland sunk into a state of both political and intellectual degradation; nor was it until towards the end of the eighteenth century that the national mind awoke from its long trance, and a reform was effected which has since produced good fruit. Whilst Konarski and a few others began to combat that maccaronic mixture of Latin and Polish which was then so much in fashion, a number of distinguished men, such as Krasicki, Archbishop of Warmia, a poet and political writer; Naruszewicz, Archbishop of Luck, a poet and historian; the two brothers Augustus and Michael Czartoryski, Albertandy, Zamojski, Potocki, Kollontay, Czacki, and many others, opened a new career for Poland; and by the impulse thus given the regeneration of literature was assured, although the liberties of the nation have been destroyed.

The first place amongst modern Polish writers is commonly assigned to John Paul Woronicz, born in 1757 and died in 1829, the archbishop of Warsaw, metropolitan primate of the kingdom of Poland, and an eminent poet and prose writer. Julian Ursyn Niemcewicz, distinguished alike as a poet, a historian, and a statesman, has been elevated by his tales to a high place amongst modern Polish writers; whilst in some of his other productions, particularly his *Powrot Posla*, or the Return of a Deputy to his Home, he has exhibited a most lively and animated picture of Polish habits and manners. Karpinski is the Burns of Poland; and Brodzinski, Felinski, and Ossolinski are likewise popular poets. Of the patriotic bards, Adam Mickiewicz is the head and prince. His effusions are generally of a plaintive character, except when they dwell with rapture on the past glories of Poland. The muse of freedom is indeed the idol of his poetical worship, and like many other great poets, he has taken from the altar of liberty that hallowed fire, the divine flame of which warms and animates his strains. Lastly, in the class of modern historical writers, no one can claim precedence of Joachim Lelewel, a name venerable in literature, and honourably known for his strict regard to truth and the liberality of his political writings.

Lastly, in closing this brief survey, a melancholy feeling is awakened in the mind. We are, in fact, writing of the past, without almost any reference to the present. Since the failure of the insurrection of 1830–1831, literature may be said to have expired in Poland, or rather to have been destroyed by the barbarous despot who has sought to proscribe her history, and even to eradicate her language; but amongst the exiles there are many men of distinguished literary acquirements whose talents and learning enable us to form a tolerable estimate of the general state of education in their native country previously to the revolution; and we know from history that high mental cultivation has long co-existed in Poland with that chivalrous heroism for which they have always been pre-eminently distinguished.

Area and population.

At the date of the first partition Poland had an area of about 282,764 English square miles, and a population of about 12,216,000.

			Square miles.	Inhabitants.
In the first partition,	Russia	obtained	41,804	1,800,000
„	Prussia	„	13,335	416,000
„	Austria	„	27,093	2,700,000
In the second partition,	Russia	„	96,372	3,000,000
„	Prussia	„	22,436	1,100,000
In the third partition,	Russia	„	42,968	1,200,000
„	Prussia	„	21,103	1,000,000
	Austria	„	17,653	1,000,000
		Total.........	282,764	12,216,000

1227. Boleslas V.
1279. Lesko VI.
1296. Prezemislas.
1300. Uladislas IV.
1300. Wenceslas.
1305. Uladislas IV. (restored).
1333. Casimir III.
1370. Louis.
1385. Hedwig.
1399. Uladislas V.
1434. Uladislas VI.
1445. Casimir IV.
1492. John Albert.
1501. Alexander.
1507. Sigismund I.
1548. Sigismund II.

A.D.
1574. Henry.
1576. Stephen Batory.
1587. Sigismund III.
1632. Uladislas VII.
1648. John Casimir.
1670. Michael-Koributh-Wieçnowiçki.
1674. John Sobieski.
1697. Frederick-Augustus.
1704. Stanislas I.
1709. Frederick-Augustus (restored).
1734. Frederick-Augustus II.
1764. Stanislas II., who died a state prisoner at St Petersburg in 1798.

(J. B—E.)

POLAND (Pol. *Polska*, Germ. *Polen*, Fr. *Pologne*), a kingdom or czarat of European Russia, forming the most westerly portion of the empire, and bounded on the N.E. and E. by Western or Polish Russia, S. by the Austrian empire, and W. and N. by the kingdom of Prussia. It is in the form of an irregular square, with a long and narrow strip of territory extending from its N.E. angle; and it lies between N. Lat. 50. 4. and 55. 5., and E. Long. 17. 30. and 24. 18. The length and breadth, exclusive of the projecting tract (which is about 120 miles long, and from 20 to 50 broad), are each about 200 miles; and the area of the whole is 49,408 square miles. Though Poland derives its name from the flatness of its surface, and is in general a very level country, yet there are some hills and undulations to break the uniformity of this extensive region. A branch of the Carpathian chain, not exceeding 2000 feet in height, extends northwards between the Vistula and its affluent the Pilica. The rest of the country slopes very gradually towards the N., being in the highest parts only 300 or 500 feet above the sea. In the more elevated regions there are numerous small lakes and morasses, and extensive portions of the country are occupied with forests and heaths. The largest river in Poland is the Vistula, which, rising at the foot of the Carpathians in Austrian Silesia, flows N.E., forming the boundary between Poland and Galicia, and then flows northwards through the kingdom. After receiving the Bug, it turns to the west, and enters the kingdom of Prussia a short distance above Thorn. It then takes a northerly course, and falls into the Baltic at Dantzic. It receives from the right the Bug and its affluent the Narew, both of which constitute, the former for a considerable, and the latter for a very short distance, the boundary of Poland towards the E. The Vistula also receives from the right the Wieprz; and from the left its chief affluent is the Pilica. The other rivers of Poland are the Warta in the west, flowing westwards to the Oder; and the Niemen, which forms the N.E. boundary, and flows into the Baltic. The Vistula and Niemen are both navigable as far as they flow through Poland or along its borders, and the Bug, Narew, and Warta, for a considerable portion of their course. In the hilly parts of the country various kinds of minerals are obtained, chiefly iron, copper, lead, zinc, cadmium, and sulphur. In 1849 the governments of Warsaw and Radom contained seventy-two private iron mines, producing ore to the value of L.47,305; and ten imperial mines producing ore to the value of L.3399. The copper obtained and worked in the same year amounted in value to L.31,127, the lead to L.437, the cadmium to L.28,311, and the sulphur from one mine alone to L.2265. The soil of Poland is fertile, producing more grain, hemp, flax, tobacco, &c., than is necessary for home consumption. Wheat is grown only among the hilly regions; in other parts, rye, oats, and buck-wheat are the crops chiefly raised. The forests supply large quantities of timber. The country contains many horses, cattle, and pigs; fewer sheep; but immense swarms of bees, which produce excellent honey. Game abounds in the forests; and there are also bears, wolves, and lynxes. The climate is warm in summer, but very cold in winter, when the country is frozen and covered with snow for four or five months of the year. Manufactures, which were formerly little attended to, and almost unknown in Poland, have recently made great advances. At the close of 1849 the country contained 82 wool-spinning factories, with 1175 machines, and 48,606 spindles; 2405 woollen cloth factories, employing 8200 hands, and producing in the course of the year 2688 cwt. of goods, valued at L.277,965; 5 cotton-spinning factories, with 460 machines, and 52,197 spindles; 9317 establishments for cotton-weaving, employing 14,156 hands, and producing L.413,785 worth of goods; 4242 linen-weaving factories, employing 7288 hands, and producing in all about 11,518,500 yards of cloth; 16 silk-mills, with 109 looms, employing 152 hands, and producing goods to the value of L.19,709; 24 manufactories of liqueurs, 47 of oil, and 20 of vinegar, producing L.26,694 worth of liqueurs, L.17,659 worth of oil, and L.10,029 worth of vinegar; and 12 breweries, producing beer and porter to the value of L.15,144. Poland also produced in the same year L.4116 worth of surgical and other instruments, L.2331 of arms, L.27,761 of glass and crystal ware, and L.48,660 of paper, &c. The trade of the country is considerable: corn, wool, oil, timber, and zinc, the chief articles of export, are conveyed down the Vistula to Dantzic; and many goods are also carried into Austria. The value of the exports to Prussia in 1851 was L.627,480, to Austria L.214,615; that of the imports was L.1,496,342. The commerce of Poland is for the most part in the hands of the Jews. The capital is Warsaw, and the kingdom is divided into five governments as follows:—

	Area in Square Miles.	Arrondissements.	Pop. (1855).
Augustowo	7,242	5	613,921
Ljublin	11,627	8	1,007,251
Plock	6,744	6	550,643
Radom	9,631	8	923,355
Warsaw	14,164	12	1,702,675
Total	49,408	39	4,797,845

The kingdom contained in 1855, 3,714,016 Roman Catholics, 572,052 Jews, and 270,412 Protestants; and the capital had 156,072 inhabitants.

POLAR REGIONS.

Arctic Regions.

THIS title embraces the Antarctic as well as the Arctic seas and lands; but we mean to confine ourselves mainly to the North Polar Regions, which, cold and inhospitable as they are, have witnessed many of the most strenuous and masterly efforts of British seamen, placed under circumstances of extraordinary peril and privation. The intensely interesting narratives of the exploits of these "marine worthies" will continue to incite the youth of the land to deeds of daring enterprise as long as Britain enjoys the blessings of free government, and its accompanying liberty of thought and action.

Phœnician voyages.

From the ancients we get but a few glimpses of the northern regions. It is true that in the very dawn of history the tin of Cornwall and the amber of the Baltic were known on the coasts of Palestine and Asia Minor, and that the Phœnicians,[1] and after them the Carthaginians, extended their commerce and commercial establishments coastwise from Tartesus or Gaddir, in the Bay of Cadiz, to the Œstrymnades, Cassiterides, or Fetis, in the south of Albion. These skilful mariners may even have penetrated in their coasting voyages into the Baltic through the Sound or Belt; but there is no evidence of their ever having crossed, or even approached, the Arctic Circle.[2] Commercial jealousy kept the secret of these voyages concealed from the Greeks, but at a later period the conquest of Britain must have given to the Romans some knowledge of the seas which wash its shores; yet it was not until 138 years after Cæsar had first ventured across the Straits of Dover that Agricola circumnavigated the island. In process of time, the Roman seamen espied the Scandinavian peninsula, which they believed to be a cluster of islands; but they did not cross the Arctic Circle, that feat being reserved for a hardier race of mariners, nurtured in a ruder clime, and on more stormy seas. After Roman civilization had been overthrown in England by invading hordes of Jutes, Angles, and other heathen tribes, and the Saxon dominion in that island was acquiring strength under the authority of one ruler, the raven flag of Scandinavia appeared in the narrow seas, carrying terror and rapine to all the coasts of Europe. Considering warfare the only honourable employment, death in the battle-field the only desirable termination of a hero's life, and accustomed to all the vicissitudes of a variable sky, the Northmen were no summer sailors; but, on the contrary, often chose the winter time for their piratical descents, as being the season when they were least expected. And so it happened that, either from being casually driven out of their course by tempests, or urged by the spirit of daring enterprise to roam over the waters in quest of new lands,—the mythic white islands and seas of the early ages,—they acquired a general knowledge of the coasts of the Northern Ocean.

Norman voyages.

About the year 890, "Octher (aliter *Audher*) said to King Alfred that he dwelt the furthest north of any other Norman at Helgoland" (on the coast of Norway, in Lat. 66. N.), and that "upon a time he fell into a fantasie to prove and know how far that land stretched northwards;" whereupon he made sail directly to the north for six days; then, after delaying till he had another fair wind, plain east for four days more; and, lastly, after waiting again for a wind, went due south, to the mouth of a large river, from whence he turned back. (Hakluyt, i. 4, 235.) Octher must have sailed 60 miles a day to have doubled the North Cape, which is a large allowance; yet as an Arctic summer would give him light enough by night, he might have gone at that rate for the twenty-four hours, and have reached the Varanger Fiord, or perhaps the mouth of the Kola; but the time is evidently too short for him to have traversed the White Sea, and attained the mouth of the Dwina, as Hakluyt supposes. Octher found the banks of the river from whence he returned so well peopled by Biarmes that he was afraid to land. The country he had previously coasted was very sparingly inhabited by fishermen, fowlers, and hunters, who were all Fynnes or Terfynnes. The Queenes (Kwæns, Kainulainen, or Fins of Latham), he further stated, were in the habit of crossing the mountains at times to the maritime coasts of Norway, for the purpose of invading and spoiling the Normans.

In 860, or thirty years before Octher made this communication to King Alfred, Iceland was discovered by the Norwegian Naddodr, visited in the following season by Gardar, a Swede, and colonized in 874 by Ingolfr and other Norsemen. Some years later, one Gunbiorn having been driven by a storm to the westward of Iceland, discovered first a few low rocks or skerries, and afterwards an extensive land, whose remarkable snowy southern headland he named *Hvidsærk* (White Shirt); and about 982 Erikr Rauði, being banished for a term from Iceland for manslaughter, sailed in quest of Gunbiorn's Land, and having found it, coasted along towards the south, and rounding the promontory of *Hvarf*, or "the turning point," spent three years in exploring the country; then returned to Iceland, where he made so favourable a report of the western land, that in 985 or 986 twenty-five vessels, carrying colonists, set out with him on his second voyage. Half of these ill-fated ships perished in the ice, but the remainder reached their destination, and in a few years thereafter all the habitable spots of Greenland were occupied. A barren district of about 80 miles divided the settlements into two groups, named the East and West Bygd, both being, nevertheless, on the western coast. Lieutenant Graah, after criticising elaborately the published accounts of these voyages, concludes that *Hvidsærk* (aliter *Muckla Jokel* and *Blaasærk*) is the lofty island now known as Cape Farewell, which is visible at the distance of 80 miles; *Hvarf* is Cape Egede, or some promontory near it; and *Herjulfrnes* (*Hernoldus Hook*), lying between the two, is the southern point of the East Bygd. The West Bygd was included within the parallels of 62½. and 66. N. Lat. One of the colonists who accompanied Erikr to Greenland was Herjulfr Bardson, a descendant of Ingulfr, the first settler in Iceland. This man's son, Bjarni, was in Norway at the time of Erikr's migration; but returning from thence in the spring of 985 or 986 to Eyras in Iceland, he found that his father had sailed for Greenland, and immediately resolved on following him, that they might spend the winter together. The crew of his ship consenting to his proposals, they put to sea again; but encountering thick, stormy weather, were driven far to the southward and westward. On the sky clearing, they found themselves in sight of a wooded part of the American coast, which, not agreeing with the description Bjarni had received of Greenland, they turned their prow northwards; and after passing several of the projecting headlands of Newfoundland and Labrador, but without landing on any, or even naming them, they finally came in sight of White Sark, where they fortunately met with a boat, and were directed to Herjulfrnes, his father's new abode.

---

[1] Such voyages in the Northern Atlantic from one advanced commercial colony to another would be easy to the seamen who, by command of Pharaoh Necho, had in the seventh century B.C. sailed from the Red Sea round the south end of Africa, and in the third year of their voyage entered the Mediterranean by the Pillars of Hercules. Herodotus, from not being able to understand one of the physical phenomena reported by the mariners, discredits this voyage; but the very circumstance of the sun having had a northerly bearing as they rounded South Africa is an evidence of its truth, and full credit is now given by competent geographers to the report. (Rawlinson's Herodotus, Introduction; Prideaux's *Connect.*, Ezekiel, c. xxvii., &c.)

[2] The volumes of Heeren on the African and Asiatic Nations (translated in 1832) contain references to all the known authorities on this subject. We there find that Gades (Gaddir) and Utica were founded about the same time, and 270 years prior to the building of Carthage, or 1130 B.C. Aristotle, quoting from the Phœnician annals, also records the foundation of Utica. (Diod. Siculus and Pomponius Mela.) Festus Avienus, in his *Ora Maritima*, composed after consulting the Punic records, mentions the naval armaments of Hanno and Himilco, sent from Africa to found colonies outside of the Straits of Gibraltar, the former on the African coasts, and the latter on the western shores of Europe. A record of the widely-diverging Phœnician trade is supposed to be preserved in the peculiar and very ancient glass-beads still in existence on the western coast of Africa, in Cornwall, and in Ireland. (Rawlinson's Herod. ii., p. 50.) The Carthaginian vessels were flat-bottomed barks, so constructed for more conveniently navigating shoal waters. Himilco's voyage northwards lasted four months, when he reached the country which yielded tin and lead. From the Œstrymnades, whether these were promontories or islands, communication with the rest of Albion was kept up in skin boats by the natives, whose chief employment was commerce. Diodorus also mentions that the inhabitants of Britain were very skilful in obtaining tin, which they conveyed at low-water to the island of Fetis (supposed to be St Michael's Mount). Much of the Cornish tin seems to have been carried across Gaul to Massilia (now Marseilles); and Pythias, a Massilian Greek, is reported to have sailed in the year 333 B.C. out of the Straits of Gibraltar along the coasts of Spain, Gaul, and Jutland to the Scaw, where he turned to the east, and passed onwards into the Baltic. This voyage was probably prompted in part by a wish to visit the amber coasts at the mouths of the Vistula. Herodotus seems to have been much puzzled by the Greek name of Eridanus applied to that river, but the appellation of Rho-daun or Rauden is still that of one of the affluents of the Vistula. (Larcher in Beloe's Herodotus; circa, 111–106 B.C.) G. Cornewall Lewis does not believe that the Phœnicians reached the Baltic, but thinks that the ancients acquired their knowledge of that sea solely from the overland traders. Yet Pliny, speaking of the *Basilia* of Timæus, a navigator who succeeded Pytheas, says that it is the same island with the *Baltia* of others. If the word Baltic did not originate in the latter name, the similarity of sound is at least remarkable. (See a paper on the Amber Trade, *Notes and Queries*, 2d series, vi. 131 and 134; by G. C. Lewis.) Juba, the Mauritanian prince, sent ships to examine the Canaries; and Sertorius, a general under Marius, meditated a retreat to these "Fortunate Islands" in the year 82 B.C.

Erikr's son Leifr, who had gone to Norway at the close of the tenth century, being, by command of the king Olaf Triggeweson, instructed in the principles of Christianity, was by him sent back to Greenland, attended by a priest, who baptized Erikr and his followers. In the year 1000, Erikr having purchased the ship in which Bjarni had traded with Norway after his discovery of America, sailed to acquire more perfect knowledge of the western country. He wintered in *Vinland*, now recognised by its position and productions as comprising Rhode Island and Massachusetts. The peninsula named at present Nova Scotia he called *Markland*, on account of its woods. Newfoundland and Labrador were termed *Litla Helluland* and *Helluland it mikla*, or the Lesser and Greater Slaty Lands. Leifr's Booths, the wintering station of the expedition, is identified by Professor Rafn with the banks of Taunton River; *Straumfiorðr* of the Norsemen with Buzzard's Bay; and *Kialarnes* with Cape Cod. Leifr, on his way back to Greenland, rescued the crew of a Norwegian vessel that had struck on a rock, and being enriched by the salvage of her merchandise, took thenceforth the appellation of *Leifr hin hapni*, or Leifr the Fortunate. Vinland was afterwards sought with the view of forming settlements by Thorwaldr Erikson, Leifr's brother, Thorfinn Karlesefne, and others; but the hostility of the Skrællings frustrated all attempts at permanent habitation. In 1008 Snorre Thorfinnson was born at *Thorfinn's Buðr*, near Taunton, being the first child of European extraction born in America. The intercourse between America and Greenland seems to have been kept up as late as 1347, chiefly, it would appear, to procure wood for building purposes.

In the palmy days of the Greenland Icelandic colonies the West Bygd had 4 churches and 90 farms (some authors say 110); and the East Bygd a cathedral, 11 churches, 190 farms, a town, and at least 2 cloisters. The *Kongskuggsiö*, or *Speculum Regale*, supposed to have been written in the twelfth or thirteenth century, mentions that the interior of Greenland is covered with ice, but that the habitable banks of the fiords abound in good pasturage, and that the colonists subsisted by raising cattle and sheep, and by the chase of the rein-deer, walrus, and seal, the climate being adverse to the production of grain. The country was governed by Icelandic laws, and had a series of bishops, beginning with Arnold, who was elected at the instance of Sokke, Leifr's grandson, in 1121, and ending with Endride Andreason, who was consecrated in 1406.[1] Before this date the colony had begun to decline. In 1348 a black pestilence had committed wide ravages among the people of the North; and in 1379 the Skrællings had utterly destroyed the West Bygd. Ivar Bere or Bardsen (translated *Boty* by Barentzoon)[2], a principal man in the bishop's court, sailing to the rescue with a levy of East Bygd people, found no man, neither Christian nor heathen, but only sheep running wild, of which he brought away as many as he could. The East Bygd held out some time longer; but in the beginning of the fifteenth century Margaret, the Queen of Denmark and Norway, called the "Semiramis of the North," having imprisoned the merchants who traded with Greenland on the charge of intercepting the tribute due to her from the colonists, and interdicted all her subjects from going thither, the settlement languished away. The final blow was, according to a pastoral letter of Pope Nicholas V., given by a hostile fleet (suspected by Graah to have been English), which in 1418 laid waste the country, and carried into captivity all the vigorous inhabitants that were found, a few dwellers in remote parishes only escaping. By a treaty between our Henry VI. and King Erik of Norway in 1433, the captives in England were set at liberty; but nevertheless the neglect of the mother country continuing, the colonists either returned to Iceland or perished under the repeated assaults of the Skrællings. Vestiges of the ancient colonization have been traced in ten different localities within the bounds of the West Bygd; and the ruins are yet more numerous and in better preservation in the East Bygd, where the walls of several churches are still standing. Runic inscriptions have moreover been discovered at the ancient episcopal site of Gardar in Eriksfiorð, and in other places. One of these, found by an Eskimo Greenlander named Pelinut, at Kingitorsoak, in Lat. 72. 55. N., Long. 56. 5. W., bears the date of 1135, and informs us that on the Saturday before *gangday* of that year, Erling Sighvatsson, Bjarni Thorðarson, and Eindrid Oddsson, cleared the ground and raised these marks. This inscription is important, as furnishing incontestible evidence of the Norrænu Greenlanders having carried their sealing expeditions into Baffin's Bay. The usual summer resort of the sealers was *Greipar*, whose site is placed by Rafn in Lat. 67., to the south of Disco, where the fiords resemble the intervals between a man's fingers, which

---

[1] Professor Finn Magnusen and several other learned Icelanders deduce their pedigree from a couple who were married in Greenland in 1409 by Bishop Endride. The sculptor Thorwaldsen also traced his descent from these ancient stocks. See *Kongs Skugg Siö*, *Islands Landnamabok*, and Rafn's *Antiquitates Americanæ*. For translations, see Beamish, 1841; Blackwell's Mallet, 1847; *Geograph. Journ.*, 1858.

[2] Purchas, ii., p. 518. In the *Relation du Groenland*, par Isaac de La Peyrère, Paris, 1663, Ivar Bardsen's name becomes Iver Bert.

greipar signifies. Disco itself was called *Bjarney* by the old colonists, meaning "bear island." We learn further from the *Hauksbok* that in 1266 the priests of Gardar, in consequence of information obtained from those who returned from *Norðursæta*, or the northern summer haunts, sent out a vessel on discovery, which, leaving Greipar far behind, came to an inlet that was named, from its curvature, *Kroksfiorðr*, beyond which they were driven in thick weather by a southerly gale. On the weather clearing, the mariners found themselves in an archipelago, amid much ice, with the sun as high above the horizon at midnight as it is in the inhabited parts of Greenland when in the north-east quarter of the sky in the same season of the year. It is unsafe on such data to fix on the sound into which this vessel was driven, as Rafn has done; but we must conclude that these adventurous Northmen, passing far within the Arctic Circle, had seen much of the shores of Baffin's Bay upwards of three centuries before it received the latter appellation.

The fate of the Greenland colonies, and the existence of the western land, had been almost wholly forgotten until the success of Columbus produced a search for ancient records, which, however, instead of being honestly published, were quoted as vouchers for many fables and much inaccurate cosmogony.[1]

Southern enterprize.

During the latter third part of the thirteenth century, when Venice was in the zenith of its prosperity, and monopolized the overland trade of Europe with India, Marco Polo, following the steps of his uncles and other merchants, travelled across Asia to Khan-balik, or Pekin, the seat of the Tartar conqueror of China, Kublai-khan. By his narratives Europe became acquainted with the condition and, approximately, with the position of China; but the project of reaching the fabulously rich lands of the extreme East by sea does not seem to have presented itself at that time to northern navigators; and maritime enterprise lay dormant until the middle of the fifteenth century, when Prince Henry of Portugal gave the impulse by which his countrymen went forth to trace the western coast of Africa down to the *Cabo Tormentoso*, the haunt of the Genius of Tempests, that most poetical creation of Camoëns. In 1492 Columbus made his glorious discovery of the Western Indies; and six years afterwards Vasco de Gama, doubling the storm-beaten extremity of Africa, which had become the Cape of Good Hope, reached India by an eastern route. These splendid achievements of the peninsular mariners stirred the spirit of northern adventure; and the sagacity of Henry VII. secured to England the services of John Cabot, and of his greater son Sebastian. How far the doings of the Norsemen in the Greenland seas were known at this period to the English cannot be easily ascertained, but it is difficult to believe that the merchants of Bristol, who traded to Iceland in the time of Edward IV., did not retain some memorials of Engröneland, Hellnland, Markland, and Vinland, of which they must have heard; yet in the absence of correct topographical description, and the entire defect of astronomical observations, these words would be mere names of remote places. No printed detail of the Norwegian discoveries was given to the world until 1705, more than two centuries after Columbus had made the first of his great voyages across the Atlantic, though, as mentioned below, some obscure notices had appeared in authors after the middle of the sixteenth century.[2] Certain it is, however, that from the Columbian epoch, whether in the spirit of enterprise inherited from their ancestral Scandinavian kindred, or, what is more likely, in pure rivalry of the Portuguese and Spaniards, the project of a passage to China in a high latitude, either by the N.W. or by the N.E., or directly across the Pole itself, began to stir the minds of English seamen. Robert Thorne, a merchant of Bristol, who had dwelt long in Spain, was the first who distinctly proposed the bold speculation of a north polar passage, which he did in two letters, one of them addressed to Henry VIII. in the year 1527, and the other to the ambassador of that monarch residing at the court of the Emperor Charles V. He adduces as one of his chief reasons for sending a naval armament that way, the discovery of three parts of the world by other princes; so that the fourth way by the north was the only one that remained to be tried. His second letter is accompanied by a map,[3] in which Asia is drawn 120 degrees of longitude too far to the east, and the North-East Passage consequently abbreviated to that extent; while China is placed far to the west of oriental Cathayo.

It does not enter into the plan of this article to give a chronological list of all the voyages to the Arctic regions which, with short intervals of rest, have succeeded each other from the time of Henry VII. down to the reign of Victoria; but having already mentioned those of former ages as fully as our limits would allow, we purpose to notice those merely of the post-Columbian ones which have brought material additions to our knowledge of the coasts of the Northern Ocean. The reader desirous of entering fully into the interesting histories of Arctic exploits may have recourse to the many valuable compilations which have of late years issued from the press.[4]

English voyages

On the 5th of March 1496,[5] Henry VII. granted letters patent to John Cabot, a Venetian, and to his three sons Lewis, Sebastian, and Sancius, to sail with five ships to all parts and seas of the East, of the West, and of the North, and to discover and possess all lands previously unknown. The expedition did not sail until the following year; and the most explicit account of its doings, though a very brief one, is that which Hakluyt copied from an engraving by Clement Adams of a map drawn by Sebastian himself, in which the discovery of the land named *Prima Vista*, and the island of St John lying off it, are ascribed to John Cabot, and Sebastian his son, as having been made on the 24th of June 1497, at five in the morning. In his translation of this Latin manuscript, Hakluyt has interpolated in brackets "with an English fleet from Bristol;" and Master Robert Thorne, above mentioned, in his letter to the English ambassador in Spain, states that his "father, a merchant of Bristowe, and Hugh Eliot, were discoverers of the Newfound lands" (being doubtless adventurers in the fleet of John Cabot). Master Thorne further intimates that if the seamen would have followed their pilot's mind, they would have gone southward, and discovered the West India

---

[1] The adventures of the Zeni in *Frieslanda*, *Eslanda*, *Engrovelanda*, *Estotilanda*, *Drogeo*, and *Icaria*, under the Arctic pole, in 1380–95, but not published till 1558, are evidently a compilation of reports, mostly fabulous, collected probably in Bristol or Scandinavia. Szkolni (Scolvus, Sclolvus, or Scalve), a Polish pilot in the service of Christian II. of Denmark, is said to have landed in Groetland in 1476 or 1477, after visiting Greenland. Master Thorne's map places Groetland in Lat. 72.; but its position is wholly uncertain, there being no authentic details of the voyage extant. Sir Humfrey Gilbert calls him *Scolmus*, and says that he entered far into the North-West Passage.

[2] The discovery of America by the Scandinavians is alluded to by Adam of Bremen in his *Hist. Eccl. Hamb. et Brem.*, written in 1073–6, printed in 1579; by Ortelius in his *Theatr. Orbis*, 1601; by Mylius, *De Antiq. Ling. Belg.* 1611; and by Grotius, *De Orig. Gent. Amer.* 1642 (Major. l. c. xii.). See also Torfæus, *Hist. Vinlandiæ*, 1705; and Olaus Magnus, *Hist. Gent. Sept.*, lib. ii., c. ix.

[3] For a fac-simile of the chart, see *Voy. to Am.*, Hakluyt Soc. pub. 1850. A map of North America, dated 1544, or 17 years after the date of Thorne's, is published in the Atlas of Baptista Agnese, of which Trinity College, Dublin, possesses a copy, and contains evidently the discoveries of the coast as far as Newfoundland and Labrador, made by Cabot, Cortoreale, and the Basque and Breton fishermen, up to the time of its construction; but there is no indication of land as high as Hudson's Strait.

[4] Coxe, Burney, Barrow, &c.

[5] Not 1495, as in Hakluyt. Consult *Div. Voy.*, Hakl. Soc., ed. J. W. Jones, Esq., p. lxviii.

Islands. Sebastian's map is not known to be in existence now, though Hakluyt says that in his time it was in many ancient merchants' houses, as well as in "Her Majestie's privie gallerie" at Westminster. The name of the English vessel that first touched the American shore is said to have been the Mathew of Bristol.

A second patent was granted in February 1498 to "John Kabotto, Venecian," in which reference is made to the "londe and isles of late found by the said John." It was probably under this patent that Sebastian armed two ships at the expense of King Henry VII., as related by Pietro Martire. This author, who was a member of the Council of the Indies to the Catholic king, says that "Sebastian Cabot, his very familiar friend, was called out of England after the death of Henry VII., and made one of our council and assistants as touching the affairs of the Indies," and further that he was told by him, that at the time in question, having two ships manned by 300 men, he directed his course towards the North Pole, and found, even in the month of July, in a manner continual daylight, and monstrous heaps of ice swimming in the sea, so that he was enforced to turn his sails and follow towards the west, along the land, where the heat of the sun had melted the ice. He coasted this land, which he named *Baccalaös,* until he reached the same parallel of latitude as the Straits of Gibraltar, in the longitude of Cuba. Authors disagree as to the northern latitude attained by Sebastian. Petro Martire, as reported by Hakluyt, and by Ramusius in one part of his compilation, says that it was 55° N. Butrigarius, the Pope's legate, who had his information from Sebastian himself, calls it 56° N.; and Gomara states it to have been 58° N., beyond the Cape of Labrador. Ramusius, again, in his *Discorso sopro la terra ferma dette del Lavorador et de los Bacchalaos,* says that Sebastian searched the land up to the 67th degree; and in his general Preface to the same volume he informs us that "Il Signor Sebastian Gabotto nostro" wrote to him many years past that, having sailed a long time W. and by N. behind the islands of *Nova Francia* up to the 67. 30. N. Lat., he found the sea open, and would have gone on to *Cataio Orientale,* if the malignity of the shipmaster and mutinous seamen had not forced him back. Sir Humfrey Gilbert, in his *Discourse on the North-West Passage,* published by Hakluyt, uses nearly the words of Ramusius, stating the latitude reached by Cabot to be 67½ degrees, and referring, like Hakluyt, to the map in the Queen's private gallery as his authority. Sir George Peckham, in a treatise on the same subject, also in Hakluyt's collection, mentions 63 degrees as the northern limit of the discoveries of the Cabots. Sebastian's "owne mappes and discourses, drawn and written by himself," were, Hakluyt says, "in the custodie of the worshipful Master William Worthington;" and though it is probable that they were, as Mr Biddle conjectures, afterwards suppressed at the instance of Philip II., they appear to have been accessible to geographers in the time of Elizabeth. Mr Richard Willis, in his argument on a North-West Passage (in Hakluyt), mentions the "table of our countryman Sebastian Cabot, which the Earl of Bedford hath at Cheinies, in which a gulf is left between 61° and 64° N., as Gemma Frisius also hath it in his globes." Taking these various reports into account, it seems probable, but by no means proved, that Sebastian Cabot anticipated Frobisher in the discovery of the strait now known as Hudson's. Thorne's chart carries the land up to the North Pole; Ramusius' stops short at the Arctic Circle; but it was evidently the custom of the map-makers of the times to carry the contour of the land a few degrees beyond the limits of the coasts actually traced. Ramusio, though he corresponded with Cabot, does not seem to have been accurately acquainted with the dates of his several voyages; and being consequently ignorant of his claim to the discovery of Labrador, he says that Gasparo Cortoreale was, as far as he knows, the first who sought to find a short way to the Spice Islands by the N.W.[1]

Cortoreale of Portugal.

This able and adventurous navigator, he tells us, sailed from Portugal with two caravels in 1500, and discovered *Terra Verde* lying between the N. and N.W., coasting it from *Rio Nevado* (Hudson's Straits), in Lat. 60., to *Rio San Lorenzo* and its gulf, called *Quadrato,* which turns at the end of *Los Bacchalaos,* whose highest point, named *Cabo di Buenovista,* lies in 48½°.[2]

English voyages.

The memorial of Master Thorne, mentioned in a preceding page, took, as Hakluyt says, present effect; and in May 1527 King Henry VIII. sent forth two ships, well manned and victualled, to seek strange regions. These ships were the Sampson, which was lost in a storm, and the Mary of Guildford, which returned to England after touching at Newfoundland, when her master, John Rut, gave a very meagre account of the voyage. Other Englishmen made at this time private adventures to the new continent, some of which Hakluyt mentions;[3] and Rondelet, whose work appeared in 1554, states that even thus early the fishery for cod had been established by the Bretons and Normans on the banks of Newfoundland.[4] The enterprising seamen of Bristol are not likely to have been tardy in seeking the same lucrative employment.

Voyages to the N.E.

The first expedition, however, which we have specially to mention is that of which Sir Hugh Willoughby was captain-general, and which sailed in 1553, after preparations on a scale beyond all previous example. The fleet, consisting of the admiral, named the Bona Esperanza, the Edward Bonaventure (Captain Richard Chancelor), and the Bona Confidentia (Cornelius Durfoorth master), dropped down from Ratcliffe to Greenwich, passing under the windows of the young king, then confined to his chamber by illness. The outfit was carefully directed by Cabot, who, as Mr Richard Eden has recorded, had long before had the secret of this voyage to Cathay in his mind; and he also drew up a detailed code of instructions for the mariners. On the 2d of August Sir Hugh took a departure from Seynam in Lat. 70. on the coast of Norway; and on the 14th saw land, computed to bear from that place E. by N. 160 leagues, and lying on the 72d parallel of latitude. This discovery, named "Willoughby's Land," is on the S.W. coast of Novaya Zemlya, between the North and South Gousinoi Nos, and has been named by Lütke the "Goose Coast," because of the numbers of these birds which breed there.[1] After plying about and sighting the land on various days, he finally bore round, and returned to the haven of Arzina in Lapland, which had been previously examined by him. Here he and his whole crew, and that of the Bona Confidentia, were miserably frozen to death, as was ascertained in the spring by some Russian fishermen. The English agent at Moscow, on hearing of the sad event, sent men to conduct the ships, the goods, and the dead bodies to England; but the ships, having become leaky, sunk by the way, carrying to the bottom both dead and living navigators. From the recovered papers, it appeared that Sir Hugh Willoughby and most of his company were alive in January 1554; but as the provisions, though calculated to last eighteen months, were found to be in part corrupt, it seems probable that the crews, weakened by low and bad diet, and their sure concomitant scurvy, were rendered incapable of resisting the severity of the climate. The great expenditure of carbon by respiration in the high latitudes, and the consequent requirement of a large increase of food, was not understood in those days, and is even at the present time seldom sufficiently provided for in regulating the diet of seamen employed within the Arctic Circle; nor are recent instances wanting of the food being bad as well as scanty.

---

[1] When the war with Scotland engaged Henry VIII.'s attention, to the exclusion of enterprises of discovery, Sebastian Cabot went to Spain, and was employed in exploring the Brazil coasts, nominated one of the Council of the Indies, and finally salaried as pilot-major. In 1548 he returned to England, was made grand pilot by King Edward VI., receiving, for that age, a large pension; and in the reign of Philip and Mary was invested with the office of "Governor of the Mysterie and Companie of Merchant Adventurers for the discovery of New Trades." Ramusio, in the *Discorso* prefixed to his third volume, attributes to Cabot a desire of discovering a short way to Cataio Orientale as the motive of his voyages; so that it must have been from ignorance or inattention to dates that he gave Cortoreale the credit of being the first to seek a passage to China by the north-west.

[2] Ramusio quotes Cortoreale's letters to the King of Portugal; but Mr P. Frazer Tytler, in his *Progress of Discovery in the Northern Parts of America,* says that the most authentic account of Cortoreale's voyage is to be found in a letter of the Venetian ambassador residing at Lisbon to Pietro Pasquiligi, written only eleven days after the return of Cortoreale to Portugal. The *Terra Verde* (which must not be confounded with the Scandinavian *Grönland*), is named, according to Mr Tytler, *Terra Cortorealis* in a Roman map dated 1508, which we have not seen. The name is preserved in Michael Lok's map of 1582. In Thorne's map of 1527 the whole coast is designated *Nova terra laboratorum dicta ab Anglis primum inventa.* Baptista Agnese's map of 1544 represents Labrador (but not so naming it) as a very broken coast, with the bottoms of the very numerous inlets left open. Its most northern part is a gulf or strait called *La Fortuna,* and probably intended for the *Golfo di Castelli* (the Straits of Belleisle). *Baccalaos* is a small island lying south of *Ilhas de los Aves,* and five or six degrees north of *Terra de los Bertones* (Cape Breton). A chart in Ramusius, designed to illustrate the narratives of Verrazzano and Jacques Carthier, represents a large *Isola de Demoni* immediately to the north of *Terra Nuova,* which is smaller, but still a large island. *Baccalaos* is one of several islets, *Capo de Ras* (Cape Race) being the most southern of them; *Isola de Bertoni* is more to the west, and *Cape Breton* adjoins the mainland of *Nuova Francia* or *Terra de Nurumbega.* In the French charts of early date *Nurumbega* is identified with the territory of the present state of Maine.

[3] Hakl. ii., p. 129; Purchas, iii., p. 809; *Div. Voy.,* Hakl. Soc., p. 54.

[4] Rondeletius (Ramusius, iii., p. 419).

The Edward Bonaventure, under command of Chancelor, captain and pilot-major, was better, or, at all events, more fortunately managed. A storm off Seynam having driven the other two ships out of sight, Chancelor made for the rendezvous at Wardhuis, from whence, after waiting seven days for the admiral, he again sailed, and eventually reached St Nicholas in the White Sea. From that place he proceeded overland to Moscow, delivered his credentials to the Czar Ivan Vasilovitch, and obtained from him many privileges for Cabot's company, which thereafter assumed the appellation of the Muscovy Company. In the following season he returned to England with his ship.

In 1556 Stephen Burrough, otherwise Burrowgh or Burro, late master of Chancelor's ship, and William his brother, subsequently comptroller of the navy, were furnished with the pinnace Serchthrift for the further prosecution of the North-East Passage. On Monday the 27th of April, the right worshipful Sebastian Cabot went on board with divers gentlemen and gentlewomen, who, after they had tasted of the cheer, and viewed the pinnace, gave to the mariners right liberal rewards; and the *good old gentleman*, Master Cabota (then eighty-eight years of age), gave to the poor most liberal alms, willing them to pray for the success of the Serchthrift. Then he and his friends banqueted at the sign of the Christopher, and for very joy of the forwardness of the intended discovery, he entered into the dance himself among the young and lusty company. Up to the 7th of June the Serchthrift was accompanied by the Edward, Captain Chancelor, and another of the Muscovy Company's vessels on their way to the White Sea, afterwards it held on its course alone to the Petchora and Waigatz Straits, which it passed through; and Stephen Burrough thus became the discoverer of the south-eastern extremity of Novaya Zemlya. Accumulations of ice prevented further progress; and the Serchthrift returned to England. Richard Johnson, one of the mariners, wrote at a later date some notices of Novaya Zemlya, and of the customs of the Samöeids, which are to be found in Hakluyt. Chancelor, on the other hand, bringing back an ambassador from Russia, together with commodities to the amount of L.20,000, had a most disastrous voyage. Only one of his ships reached the Thames, two were wrecked on the coast of Norway, and the Edward was driven ashore in a very dark night at Pitsligo in Scotland, when the ambassador succeeded in reaching the land, but Chancelor himself was drowned.

Though the Muscovy Company were much occupied in prosecuting their inland commerce through Russia to Persia, they renewed from time to time their attempts to find a passage eastward along the northern coasts of Europe and Asia. With this view, they instructed their agents to collect information respecting the mouths of the Ob and other large rivers that flow into the Arctic Sea; and they sent out at least two sea expeditions, one in 1568, under Bassendine, Woodcocke, and Browne, of whose proceedings nothing is now known; and the other in 1580, under two able and persevering seamen, Arthur Pet and Charles Jackman, but they also, after visiting Novaya Zemlya, and entering the Sea of Kara by the opposite side of Waigatz Island to that by which Burrough had passed, were arrested in their progress eastward by large masses of ice. Purchas has preserved some papers written by Antonie March, a chief factor of the Moscovy Company, from which it is clear that, previous to the year 1584, an English vessel had crossed the Sea of Kara to the mouth of the Ob, where it was wrecked, and the crew murdered by the natives.

Dutch north-east voyages.

The Netherlanders had witnessed with no small commercial jealousy the progress of the English in Russia, and after trying in vain, through the agency of John de Walle, merchant-ambassador at the court of the Czar, to shake the credit of the Muscovy Company, determined to compete with them in the search for the North-East Passage. Middleburgh, Enkhuysen, and Amsterdam were the towns chiefly concerned in this enterprise; and the citizens of the latter wisely entrusted their ship to William Barentzoon (by abbreviation Barentz),[2] who was peculiarly fitted to direct an expedition of discovery, being endowed with courage and perseverance, to which he united nautical and astronomical skill, with great fertility of resource. His writings, preserved by Purchas, further indicate that he had prepared himself for such a service by consulting the Icelandic records of the ancient voyages.[3] In his first voyage, performed in 1594, Barentzoon rounded the north end of Novaya Zemlya, to the islands of Orange, at its extreme point. In the second, undertaken in the succeeding year, Barentzoon was nominated pilot-major of a squadron, of which Cornelius Corneliszoon was admiral-superintendent. The fleet entered the Sea of Kara, but effected no discovery. In the third and most memorable of these Dutch voyages, Barentzoon was again chief pilot, while Jacob Van Heemskerck and Jan Corneliszoon Rijp were captains. It was Barentzoon's intention to have proceeded to Cape Taimur[4] by the north end of Novaya Zemlya; but, yielding to the urgency of Rijp, he kept much to the westward, and on the 9th of June discovered Bear Island, which seven years later was named Cherie Island by Stephen Bennet, a shipmaster in the service of the Moscovy Company. From Bear Island Barentzoon held a northerly course; and on the 19th of the same month fell in with land in 74. 49. N. Lat., being the N.E. land of Spitzbergen, but thought by him at the time to be part of Greenland. Passing to the S. of this land, through Vaigats or Henlopen Strait, he rounded the north end of that island now known by the appellations of New Friesland and North Spitzbergen, and passing a few miles above the 80th parallel, and then steering S. along the western shores of Spitzbergen, he returned to Bear Island on the 1st of June. Here Rijp separated from him, and sailed to Bird Cape, in the north of Spitzbergen, and from thence home; while Barentzoon, resuming his original design, made for the north end of Novaya Zemlya, which he succeeded in doubling, but was eventually icebound on the 26th August in Ice Haven, lying in Lat. 75. 45. N. There he and his companions were forced to stay, "in great cold, poverty, misery, and grief all that winter," till the 14th of June 1597, when, having previously buried two of their company, and being all reduced by scurvy to a state of extreme weakness, they departed in two open boats or schuits, to retrace the W. coast of Novaya Zemlya, and to strike over to the Russian and Norwegian coasts. The death of William Barentzoon almost at the commencement of this perilous boat voyage, says Gerit de Veer, one of the company, put us in no small discomfort, as he was the chief and only pilot on whom we reposed ourselves under God. Deprived of their skilful leader, the survivors made a greater circuit than they intended, and suffered grievously from want of provision; but at length they reached the river Kola, where they were most unexpectedly welcomed and tenderly relieved by Corneliszoon Rijp, from whom they had parted the year before at Bear Island, and who had, fortunately for them. come that year to Lapland on a trading voyage.[1]

English north-west voyages.

The further exploration of the seas and coasts of Northern Europe and Siberia having been made at much later dates by the subjects of Russia, we now turn to the English voyages undertaken for the discovery of a *North-West Passage;* and first in order are the three voyages of Sir Martin Frobisher in the years 1576–77–78, and consequently eighteen or nineteen years prior to those of Barentzoon, above mentioned. Frobisher's projected enterprise was met at the outset by strong opposition on the part of the Muscovy Company, which was overcome by a mandate from the lord treasurer; and Michael Lok pledged his means and credit for the equipment of the ships. The first expedition, projected on a small scale, consisted of two barks of 20 or 25 tons a piece, and a pinnace of 10 tons, manned by 35 men in the aggregate, victualled and found for twelve months. At Greenwich the mariners, apparelled in sky-coloured cloth, discharged their ordnance, "according to the order of war;" and Queen Elizabeth, standing at an open window, returned the salute by waving her hand. On the 11th of July land was discovered in Lat. 61., "rising like pinnacles of steeples, and all covered with snow," which is now known to have been Cape Desolation, or *Torsukatek*, at the N.W. extremity of the deserted colony of East Bygd in Greenland, but which was thought at the time by our navigators to be "Friseland." At this period Greenland was supposed to lie to the N., in the position of what was afterwards ascertained to be Baffin's Bay. Off Friesland the pinnace foundered in a storm, carrying down her crew of four men; and the Michael, one of the barks, "mistrusting the matter," returned to England, and reported that Frobisher had been cast away. Frobisher, however, stood on to the westward in the Gabriel, and, "knowing that the sea at length must needs have an ending, and that some land should have a beginning, determined therefore at least to bring true proofe what land and sea the same might be, so farre to the north-westwards beyond any man that has heretofore discovered." On the 28th of July (20th, G. Best) he saw a headland which he named "Queene Elizabeth's Foreland," but was prevented from approaching the coast by ice till the 11th of August, when the latitude at noon was 63° 8', and that day he entered the strait, "which he named after his name, Frobisher's Streights, like as Magellanus at the S.W. end of the world." So he entered the same, and passed above 80 leagues therein, having on the "right hand as he sailed westward a great maine, which he judged to be Asia, there divided from the firme of America, which lieth upon the left hand."[2] The strait was subsequently ascertained to be bounded on both sides by islands and not by continuous land. The entrance is described by Best in his account of the second voyage as follows:—"About noone we made the *North Foreland* (Cape Labrador of Hall), otherwise called Halles Island; also the small island bearing the name of the said Hall, whence the ore was taken. . . . This North Foreland is thought to be divided from the continent of the northerland by a little sound which maketh it an island, and is thought to be little less than the Isle of Wight, and is the first entrance of the straights upon the norther side, and standeth in the latitude of 62° 50' N. . . . Queene Elizabeth's Foreland being the entrance of the streits of the southerland, standeth in the latitude of 62° 30' N., northwards of Newfoundland, and upon the same continent, for anything that is yet known to the contrary. . . . The narrowest place of the straights from land to land, between Jackman's Sound and the Countesse of Warwick's Sound, which is reckoned scarcely thirty leagues within the straights from Queene's Cape, was judged nine leagues over at least." Gabriel's Island is 10 leagues within the straits, and Prior's Sound 10 leagues farther. Beyond that is Thomas Williams' Island; and N.W. from it, at the distance of 10 leagues, is Burcher's Island, which is the farthest land attained by Frobisher. Trumpet Island is between Williams' and Gabriel's islands, Mount Warwick is on the S. side of the straits, and Leicester Island and the Countess of Warwick's Sound on the N.

Frobisher, on his first return to England, "was highly commended of all men for his great and notable attempt, but specially famous for the great hope he brought of the passage to Cataya;" and the queen condescended to name the islands on both sides of the straits *Meta Incognita.* A piece of black stone, brought home by one of the company, being submitted to one Agnello, who (by coaxing nature, as he privately said to Michael Lok) obtained therefrom a grain of gold; thereupon the gold-finers promised great matters for more of the same, and a greater opinion was kindled in the hearts of many to advance the voyage again. On the second and third voyages, accordingly, discovery was repressed, cargoes of ore being the sole object; fifteen sail were engaged to bring home this worthless stuff in 1578; and luckless Michael Lok again pledged his credit for the outfit. On this third voyage, off the Queen's Foreland, the fleet encountered a great storm, in which the bark Dennis foundered. A swift current from the north-east meanwhile carried the fleet into *Frobisher's Mistaken Strait*, now known by the name of *Hudson's Straits*. Part of the fleet following the general, "entered within the said doubtful and supposed straights, having alwayes a faire continent upon the starboorde, and a continuance still of an open sea before them; and had it not been for the charge and care he had of the fleete and fraughted ships, the general both would and could have gone through to the South Sea, and dissolved the long doubt of the passage which we seek to find to the rich countrey of Cataya; . . . and where in other places we were much troubled with yce, as in the entrance of the same, so, after we had sayled fifty or sixty leagues therein, we had no lets of yce." After many days, Frobisher turned through a great sound into Frobisher's Straits; and the Gabriel having been sent round, proved the Queen's Foreland to be an island.[1] Best tells us nearly as much of *Meta Incognita*, its natural productions and inhabitants, as we know in the present day. "It is now found," he says in one passage, "that Queene Elizabeth's Cape, being situated in latitude 61½°, which was before supposed to be part of the firme land of America, and also all the rest of the south side of Frobisher's Straites, are all several islands and broken land, and likewise so will all the north side of the said straites fall out to be; and some of our companions being entered above sixty leagues within the *Mistaken Straites*, in the third voyage mentioned, thought certainly that they had descryed the firme land of America towards the south, which I think will fall out to be. These broken lands and islands being very many in number, do seem to make there an *archipelagus*, which, as they all differ in greatnesse, form, and fashion, one from another, so are they in goodnesse, colour, and soyle much unlike. They are all high lands, mountanous, and in most parts covered with snow all the summer long."[2]

---

[1] The most remarkable event during the winter in Novaya Zemlya was the unexpected re-appearance of the sun on the 25th of January 1597, indicating a refraction of 3° 49'. (For explanations and comments on this occurrence, we refer to the pages of Dr Beke, *lib. cit.*)

[2] The true position of Frobisher's Straits was long debated, and some charts placed them at the southern point of Greenland; but by the aid of Sir Humfrey Gilbert's map, bearing date 1576, and of modern surveys, they are doubtless correctly laid down in the Admiralty circumpolar chart of 1855. Hakluyt gives two narratives of each of Frobisher's three voyages, which do not always coincide in the dates and names of places. The astronomical observations appear to have been ascertained, or at least recorded, chiefly by Christopher Hall, master of the Gabriel in the first voyage, of the Ayde in the second, and chief pilot of the fleet in the third. Lieutenant George Best occasionally quotes the sayings of Frobisher, his chief, but seems to have copied Hall's latitudes. Neither Master Dionise Settle nor Thomas Ellis notice the latitudes or longitudes. The latitudes were taken with the staffe rather than the astrolabe, because the degrees of the latter were too small to observe minutes.

On each of the three voyages, "Frizeland," as they continued to call the Greenland coast, was seen; and on the third voyage, on the 20th of June, after sailing for a time along "a very hie and cragged land, almost cleane covered with snow," they landed on a place somewhat void of ice. There they saw certain tents made of skins, and boats (kayacks), much like those of Meta Incognita; but along with the usual Eskimo furniture there was found a *box of nails*, whence it was conjectured that the natives had traffic with other nations. Ellis, who mentions this fact, adds no description of the nails, from which we might learn whether they had been extracted from some ancient colonial buildings, or from the timbers of some wreck. Frobisher was the first who is known to have landed on Greenland after the Scandinavian settlements had perished, and he took possession of the country in the name of Queen Elizabeth, calling it West England, and naming a high cliff "Charing Crosse."

The search for the North-West Passage was again promoted in 1585–6 and 1857 by the merchants of London, who committed the charge of the enterprise to Master John Davis. In his voyages, as in Frobisher's, the coast of Greenland was always either sighted or landed upon, though it was generally named Friseland, the appellation of Greenland (Danice *Grönland*) being at that epoch restricted to the coasts opposed to Iceland, and lying in the vicinity of Cape Farewell. A portion of the west coast was, as has been mentioned, named West England by Frobisher; and Davis called a part of the same coast, still further north, the *Land of Desolation*. On one fiord, lying in Lat. 64. 15., which he termed Gilbert's Sound, and where he had many interviews with the Eskimos or Skrællings, the Moravian missionary settlements of Godhaab and Nye Hernhut have been established in modern times. Leaving this fiord, Davis stood to the westward, and discovered land in 66. 40. N. Lat., altogether free from the "pester of ice, and ankered in a very faire rode, under a brave mount, the cliffes whereof are orient as golde." This conspicuous hill was named Mount Raleigh, the anchorage Totnes Rode, and the sound which compasses the mount, Exeter Sound; the foreland towards the north was called Dier's Cape, and the southern one, which projected farther, Capé Walsingham. Coasting the land southwards, Davis came to the Cape of God's Mercy; and keeping close to the north shore because of fogs, found, when clear weather came, that he had shot into a very fair passage, in which he sailed sixty leagues, when he arrived at certain islands having an open passage on both sides. These islands were named, on the third voyage, in honour of the Earl of Cumberland; and Davis then ascertained that the inlet was separated merely by a chain of islands from Frobisher's Straits, which was renamed by him Lumlie's Inlet, and described as a great passage twenty leagues broad. The southern headland of Lumlie's Inlet, named Warwick's Foreland, stands near the 62d parallel of latitude. This headland is also the north promontory of another very great inlet, whose southern cape he terms "Chidleis." Warwick's Foreland is evidently the north or back of Resolution Island of the modern charts, and Cape Chidley the south portal of the Mistaken Strait of Frobisher, or Hudson's Strait. Cumberland Strait has of late years been explored by the whale fishers, and chiefly by Captain Penny, who has named an arm of it running to the north Hogarth Sound. There he has wintered for several years, and carried on a very successful fishery.

In the earlier part of his third voyage, Davis, keeping near the Greenland coast, as the whalers are at the present time accustomed to do, in the spring reached Lat. 72. 14. N., and on the 30th of June had the sun five degrees above the horizon at midnight. The land lying to the east he named the *London Coast*, and a passage south of Upernavik, called by him Sanderson's Hope, is now identified with the *Kosarsuik* of the natives.[3]

Of the northern passage now known as Davis' Straits,

---

[1] La Peyrouse, on his way to attack the Hudson's Bay Company's forts, entered Frobisher's Straits by mistake, but afterwards found his way into Hudson's Straits and Bay probably by the sound through which Frobisher passed.

[2] The ore which Frobisher had hazarded so much to procure was found to contain no metal, and poor Michael Lok, being unable to redeem his suretyship, was shut up in the Fleet Prison, and himself and his fifteen children involved in ruin.

[3] In the narrative of the first of Davis' voyages, the necessity of increasing the daily allowance of food in high latitudes is made evident, and incidentally the existence of the Newfoundland cod fishery is indicated in the following passage:—"The men fell in dislike of their allowance, because it was so small, on which every mess of five had four pounds of bread a day, twelve wine quarts of beere, six *Newland fishes*, and on the flesh days a gill of pease more; so we restrained them from their butter and cheese." Part of Davis' fleet was employed in fishing for cod on the Labrador coast while the rest were on discovery in the north; and he mentions that in Lat. 52. he met a "Biskaine" fishing, as he judged, for whales, of which there were many in that sea. Another passage deserves to be quoted. "While the captain was rowing to the shore (of Greenland), our men saw woods on the rocks, ... but I could not discern them." This illusive vision of woods was evidently an instance of the strange effects of refraction so common

Davis himself says,—"I departed from the London Coast (of Greenland), thinking to discover the north parts of America; and after I had sailed towards the west forty leagues, I fel upon a great banke of yce (the middle ice of the whalers): the wind being north, blew much, and I was constrained to coast the same towards the south, not seeing any shore west from me, neither was there any yce towards the north, but a great sea,—free, large, very salt and blew, and of an unsearchable depth. . . . By this last discovery it seemed most manifest that the passage was free and without impediment toward the north; but by reason of the Spanish fleet and unfortunate time of Mr Secretarie Walsingham's death, the voyage was omitted, and never sithens attempted." Mr Sanderson, however, Davis' steady friend, had a globe constructed, exhibiting all that navigator's discoveries, and which is said to be still preserved in the Middle Temple.

Henry Hudson is the next north-west discoverer of note. His first voyage, in 1607, was a bold attempt to cross the Pole. After passing the latitude of Iceland, he held to the west, with the intention of rounding the north end of Greenland, but on the 14th of June he descried a high and bold headland, with a castellated hill behind it, which he named the Mount of God's Mercy; and afterwards he came, in Lat. 73. 30., to a cape, which he named Hold with Hope. Steering from thence north-eastward, he had a faint view of Spitzbergen enveloped in fog; and pushing onwards as the ice and weather permitted, he reached the parallel of 81½., and saw continuous land stretching to 82. N. This land must have been a north-easterly extension of Greenland, for Spitzbergen does not go beyond 80½. N.; and granting the correctness of his latitudes, Hudson's extreme is the most northerly land known, except Mount Parry of Kane's Grinnell Land. His further progress being barred by ice, he came home, and reported most favourably of the Greenland seal fishery.

Another voyage of Hudson had for its result the discovery of Hudson's River, at whose mouth the most important city of the New World has since arisen; but his fame rests chiefly on his last voyage, on which he perished miserably through a mutiny of his men. Previous to this most lamentable end of his honourable career, he had sailed through Hudson's Straits into the bay which also bears his name, its northern and southern portals being called respectively Wolstenholme and Sir Dudley Digges. Turning to the south, past the latter, he coasted the western shore of Labrador; but at this point his own narrative closes, and for the rest we have only the doubtful story of Abbacuck Prickett, one of the mutineers, though, he avers, an unwilling one. He reports that a convenient winter harbour was not found till the 1st of November; that the crew suffered greatly from their ignorance of the climate, and became discontented, disobedient, wasteful, and selfish. On the 21st of June, when they had left their harbour, the mutiny came to a head; and Hudson was seized, bound, and driven, along with his son, into the shallop. The carpenter being overpowered, after a gallant defence, insisted on sharing the fate of his master; and six sick and infirm seamen were also forced into the boat. None of the party thus inhumanly abandoned were ever heard of again; but retribution speedily fell on the leading mutineers, who were killed at Cape Digges in an assault of the Eskimos. After great sufferings from famine, the survivors reached England, Bylot, who became a celebrated pilot, being of the number.

Sir Thomas Button, accompanied by Bylot and Prickett, prosecuted the discovery in 1612–13, taking the route of Hudson through the straits. Passing a southern point of Southampton Island, which he named Cary's Swan's Nest, he reached the western coast of the bay in Lat. 60. 40., and because it arrested his progress in that direction, he called it *Hopes Checked.* Turning southwards, he entered Nelson's River in Lat. 57. 10., and there wintered. The estuary of the river he named Button's Bay, and the adjacent country New Wales. His crew experienced the usual miseries of scurvy, but were recruited by the large quantities of birds and fish which they procured in spring, and were able to resume the voyage in the summer of 1613. In advancing northwards along the coast of the continent, a strong tide was felt off the mouth of the Missinippi or Churchill river, and being considered by the pilot to be a favourable sign, the locality was designated, after him, *Hubbart his Hope.* On the 29th of July the voyage out ended in Lat. 65., somewhere near Whale Point, and the land south of it was named *Ut Ultra.* On the homeward voyage Cape Southampton was rounded, and an island to the eastward of it discovered, and named Mansel, since erroneously written Mansfield on our charts.

In 1612 further acquaintance was made with the coast of Greenland by James Hall and William Baffin, who went thither to look for a gold mine reported to have been worked by the Danes, probably under Admiral Munck. This was sought for at Cunningham's river or fiord, in the district of Holsteinburg; but no metal was found, though traces were discovered of former diggings. Baffin, associated with Bylot, afterwards passed through Hudson's Strait; and Mr Rundall has published an unmutilated version of Baffin's journal, together with his chart, which furnish conclusive evidence of his knowledge of the art of navigation, but add nothing to Sir Thomas Button's previous discoveries. One passage, however, of the journal deserves quotation:—"Doubtless there is a passadge, but within this strayte, whom is called Hudson's Straytes, I am doubtfull, supposing the contrarye. But whether or no I will not affirm, , . . . and my judgment is, if any passadge within Resolution Island, it is but some creek or inlett, but the mayne will be up *Fretum Davis.*"[1]

In accordance with the above opinion, the same navigators sailed in 1816 up Davis Strait, and coasted the whole of Baffin's Bay, naming in succession *Woman's Islands,* in Lat. 72. 45.; *Horn Sound,* in 73. 45.; *Digges Cape,* in 76. 35.; and 12 leagues onward, *Wolstenholme Sound,* having an island in its entrance. They were next embayed during a storm at the entrance of *Whale Sound,* in Lat. 77. 30.; and after passing *Hakluyt's Island,* saw another great sound running to the north of 78°, and observed with surprise that their compass varied five degrees to the westward. This sound was named after *Sir Thomas Smith.* Descending along the western side of Baffin's Bay, *Carey's Islands* were next seen; and, on the 10th of July, the boat being sent on shore at the entrance of a fair sound, to which they gave the name of *Alderman Jones,* brought back a report of plenty of sea-morses, but no inhabitants. On the 12th, Sir James Lancaster's Sound was discovered, but a ledge of ice then lying across it prevented Baffin from crossing the true threshold of the North-West Passage. In his letter to his patron Sir John Wolstenholm, this able and adventurous navigator explains why these various sounds were not explored. Off Wolstenholme the ship drove with two anchors ahead, and was obliged to haul off shore with a low sail. At Whale Sound an anchor and cable were lost; and the wind continued to blow so strongly when he was off Sir Thomas Smith's and

---

in an icy sea, and so well illustrated by Dr Scoresby, which was denominated *Fly-land* by Luke Fox, and may be called *Fata glacialia,* being as marvellous and equally beautiful as the *Fata Morgana* of the Faro di Messina. Moreover, it furnishes a solution to the story of woodlands seen from the Busse of Bridgewater, one of Frobisher's fleet, and the fable of the *Sunkenland of Busse.*

[1] Rundall, Hakl. Soc.

Whale sounds that the ship could not remain at anchor, and the crew of seventeen were wholly employed in working her during the rough weather. Baffin, however, came to the conclusion that he had been coasting a great bay, and that there was no passage, nor hope of a passage, that way,—an opinion now known to be erroneous, but singularly coincident with that of a late navigator who retraced Baffin's course. The chart of Baffin's voyage was subsequently published by North-West Foxe. Nothing further was effected in this direction till 1819, notwithstanding that the Davis Strait whale-fishery was actively carried on during the two intervening centuries; but no charts were published by the whalers, either through incapacity, or from the narrowness of commercial jealousy, and geographers continued to give fanciful delineations of James's Island, and of the position of Baffin's Bay, till a recent date. The strongly-expressed opinion of Baffin had probably much weight in turning the search for a passage from this quarter to the northern outlets of Hudson's Bay; and thither, accordingly, various expeditions were directed.

Jens Munck.

The Danes had not seen unmoved the efforts of England; and Jens Munck, who had previously made some voyages to Greenland, entered Hudson's Bay in 1619, and wintered in Churchill River, to the estuary of which he gave the name of *Munckenes Winterhaven.* The neighbouring coasts were called *New Denmark;* and in like manner he bestowed the name of his sovereign Christian IV. on Hudson's Strait and Bay, but discovered no new lands. All his people, except two, perished of famine, or its dire attendant, scurvy; but with these two he managed to navigate the smaller of his vessels back to Europe.

English north-west voyages.

The voyages of Captain Luke Foxe, or, as he delighted to call himself, "North-West Foxe," and of Captain James, undertaken independently in 1631–32, aided the search for a North-West Passage by negativing a westerly outlet from Hudson's Bay, below the highest latitudes to which they attained. Foxe in his first year went to the westward of Southampton Island, and named a small island, lying in Lat. 64. 10., *Sir Thomas Roe's Welcome,* a designation which was afterwards transferred to the channel in which the island is situated. In the following season he tried the other side of Southampton Island, and coasting the eastern shore of Bylot and Baffin's *North Bay,* attained the latitude of 66. 47., which became *Foxe's Farthest.* The various headlands of a large island lying across the western extremities of Frobisher's and Cumberland straits were named by him King Charles his Promontory, Cape Maria, Lord Weston's Portland, and Point Peregrine; the latter being the northern extremity of the island. By a deep arm of Cumberland Sound, running to the westward, and bearing the native name of *Tenudiakbeek,* there is an Eskimo route from Davis Strait to the coast near Point Peregrine, a large sheet of water named Lake Kennedy, lying midway.

For almost a century after these voyages, or from the time of Charles I. till after the accession of George I., civil wars and revolutions at home, and the wars of Marlborough abroad, engaged the attention of the nation, to the exclusion of maritime discovery, the only effort in that cause being an abortive attempt by Captain James Wood in 1676, undertaken through the influence of the Royal Society, to make the North-East Passage by way of Novaya Zemlya.

In 1719 the Hudson's Bay Company fitted out an expedition of discovery, consisting of a frigate commanded by Captain George Barlow, and a sloop by Captain David Vaughan, but placing over both Mr James Knight, ex-governor of several of their factories, who had attained the mature age of eighty years. This expedition sailed northwards between Southampton Island and the main; but not returning when expected, was at first supposed to have reached the Pacific. In 1722, however, one Scroggs being sent to look for them, found himself to be incompetent to contend with the shoals and rocks of that coast, and returned after having picked up some fragments of ships' fittings on *Marble Island,* which is identical with the *White Island* and *Brook Cobham* of Foxe. In 1747 other remains were found on the same island by Captain Smith; but it was not until 1748 that a Hudson's Bay sealing-smack discovered the wrecked ships lying under water in a cove of the island, and ascertained the fate of the crews from the Eskimos. That people reported that when the English entered the cove, with their vessels much damaged, their numbers were about seventy. At the close of the winter only twenty remained alive, though they received occasional supplies of provision from the natives, in exchange for articles of iron, which the blacksmith was constantly employed in forging. A second winter made a still greater breach in the numbers of the unfortunate outcasts, and when the Eskimos next visited them in summer, only two remained alive. These sad survivors went frequently to the top of a rock, and gazed earnestly to the S.E., as if they expected relief from thence, but seeing no friendly sail, they sat down and wept. At length one of these melancholy men died, and the other, exhausted in the attempt to bury him, fell into the unfinished grave, and therein breathed his last.[1]

In 1741–42 Captain Middleton, a shipmaster of the Hudson's Bay Company, was engaged by the Admiralty to attempt further discoveries up the *Welcome,* as the passage to the west of Southampton Island had come to be called. After wintering in Churchill River, he proceeded northwards, and discovered *Wager Inlet* and *Repulse Bay,* the south headland of which he named *Cape Hope.* Further advance being impeded by ice, he walked over high land to the north-eastern extremity of the bay, and from thence beheld a *frozen strait* running round the north end of Southampton Island towards Cape Comfort and the North Bay of Baffin. Sir Edward Parry, eighty years afterwards, proved the perfect correctness of Middleton's report; but Mr Dobbs, who had stood out as the patron of the voyage, could not brook his disappointment in the result, and became a bitter controverter of Middleton's honest and seaman-like statements. The voyages of the Dobbs and California in 1746–47, in the same direction, fell short of Repulse Bay, but, as far as they went, the reports made of them agreed with those of Middleton. Dobbs, who took an active part in sending the ships out, seems to have infused a spirit of contention among the officers, and, as a result, we have a double set of names imposed on the headlands, and two polemical narratives. *James Douglas Bay* is synonymous with Rankin's Inlet, *Chesterfield Inlet* with Bowden's Inlet, and so on. (The correct positions of the inlets and promontories of this coast have been very recently ascertained by Dr Rae, chief factor of the Hudson's Bay Company. This enterprising and skilful traveller in 1854 ascended the River Quoich, from the north side of Chesterfield Inlet, for two degrees of latitude, until he crossed the parallel of Wager Inlet, passing within about 20 miles of its head waters, and at about 80 geographical miles direct from the nearest bend of the Great Fish River.)

After slumbering for a quarter of a century, the spirit of North-West discovery was again awakened by the Hudson's Bay Company, who sent Samuel Hearne to the mouth of the Coppermine River. This fur-trader had few of the qualifications of a discoverer, except a knowledge of the customs of the country and some acquaintance with the native languages. His astronomical observations were altogether erroneous, and he placed the junction of the river with the sea in Lat. 71. 54. N., and Long. 120. 30. W.; while the true numbers, as afterwards ascertained by Sir John Franklin, were 67. 48., and 115. 47. The latter saw the sun set there on the 17th and 18th of July, while Hearne reports it to have been "some height," or, in his manuscript, "a handspike" high at midnight on the same day of the year. Hearne's narrative of his journey is interesting; but that he was able to reach the Coppermine at all was owing to the energy of his guide and leader Matonabbee, an intelligent Northern Indian chief.[1]

---

[1] Hearne.

The Admiralty expedition in 1773 to Spitzbergen, under Captain Phipps, afterwards Lord Mulgrave, effected nothing in the way of discovery; but the press at this period teemed with publications on the probability of a North-West Passage; and this expedition was a feeble compliance with the public desire for an effort towards its accomplishment.

Russian voyages.

We turn to the progress of Arctic discovery on the coasts of the Russian empire; and it may simplify our statements if we premise that we know now the *Sievero Vostochnoi Noss*, or the "North-East Cape," to be the most northerly point of Asia. It lies on the 100th meridian, and reaches the 78th parallel of latitude, extending higher than *Cape Taimura*, is much to the N. of any part of the American continent, and has never been doubled in a sailing-vessel or boat. It is the Cape Cheliuskin of Middendorf and Peterman.

No ship coming from Europe has passed to the eastward beyond the *Sea of Kara* or *Korskoie*, and the whole N. coast of Asia has been discovered exclusively by Russian subjects, mostly Cossacks, employed to compel the Samöeids, Ostiaks, Tunguses, Jakuts, and Tchuktches, to acknowledge the imperial authority, and pay the customary *yassak* or tribute. In 1598 Fedor Dyakow demanded yassak from the Samöeids of the Jenisei; and in 1610 some fur-hunters descended to the mouth of that river, and traced the coast-line eastward to the *Pässida*. The Cossacks in 1630 discovered the *Lena;* and in the course of a few years thereafter, that river, the *Olekma*, and the *Lana*, were pursued down to their efflux in the Arctic Sea, the Tunguses of the district being then for the first time subjected to yassak. At the same epoch Ivanoio discovered the Indigirka, and carried the survey of the coast onwards to the Alaseia, 153 degrees E. of Greenwich. In 1644 the Cossack Michael Staduchin formed a winter establishment on the delta of the *Kolyma*, which has since expanded into the town of *Nijnei Kolymsk;* and this adventurer was the first who got intelligence of the Tchuktches who inhabit the north-eastern extremity of Siberia. The same Staduchin afterwards navigated the Polar Sea eastward to *Cape Chelagskoi* or *Erri Noss;* and in 1648 Semen Deshnew, also a Cossack, sailing from the Kolyma, rounded the north-eastern corner of Asia, and passing the strait now bearing the name of Bering, entered the *Gulf of Anadyr*, where he suffered shipwreck. The *Svätoi Noss*, or Sacred Promontory of this voyager, is the same with *Cape Chelagskoi;* but the true *Swatoi Noss*, so named by the Russians because of its dangerousness, projects between the *Indigirka* and the *Lena*, and was first doubled by the Cossack Timolei Buldakow in 1650.

In 1728 Captain Bering[2] and Lieutenant Tchirikow sailed from Nishnei Kamtschatka Ostrog, on the E. coast of the peninsula of Kamtschatka, and coasted the W. side of the straits which divide Asia from America, leaving St Lawrence Island on the right, seen dimly through a fog. Other portions of the northern coasts have been traced by traders or officials in the employ of the Russian government, among whose names those of Demetrius Laptew and of the merchant Liakhow stand out prominently. The efforts of the former were chiefly directed to doubling the *Sieveroi Vostochnoi Nos*, but he could not bring his vessel within two degrees of latitude of its extremity, and therefore he crossed the promontory on sledges, by which he reached *Lake Taimura* and the bay of that name. Liakhow also partially explored the islands that lie to the N. of the Swatoi Noss, which, by decree of the Empress Catherine, were named after him. He likewise coasted the continent to the eastward of the Kolyma. Much of the survey here briefly alluded to was very imperfectly mapped, and as the narratives were scanty and vague, it was not until Baron Wrangel and Lieutenant Anjou had accurately surveyed the coasts between the 125th meridian and Bering's Straits, that it was possible to understand what their predecessors had effected.

Arctic America.

Until the eighteenth century, expeditions of discovery from England had been equipped chiefly by private adventurers, with ulterior mercantile views, and even when the sovereign countenanced the enterprise, it was as patron merely, or as a small shareholder. Captain Middleton's voyage to Repulse Bay began a new order of things, in which naval expeditions, fitted at the national expense, sailed under the direct authority of the Admiralty. Later in the century voyages round the world were made in king's ships by Byron (1764), Wallis (1768), Carteret (1769), and on a more systematic plan, and with more important results, by Cook in 1768–71. The third voyage of this great navigator was undertaken in 1776, mainly for the purpose of ascertaining the existence or non-existence of a passage between the Northern Pacific and Atlantic oceans. His careful examination of the American coasts from the 58th parallel of latitude northwards, proved that there was no passage lower than *Icy Cape*, which was the limit of his voyage within Bering's Straits. He was, it is true, prevented by a gale of wind from examining the place of the pretended *Strait of Da Fonte*, supposed to lie between the 50th and 55th parallels; but he considered the reports of its existence to be "improbable stories that carry their own refutation with them;" a judgment which was confirmed by Vancouver's minute and accurate survey, made between the years 1790 and 1795. The Russian surveyor Gwosden had seen the American side of Bering's Straits in 1730; and Bering, Tchirikow, and De Lisle had rounded the peninsula of *Alaska*, and touched on the coast near *Mount St Elias*, and also in Lat. 55. 30. in 1741; but Cook was the first who made a continuous and effective survey of those coasts. The failure of Phipps in the Spitzbergen seas, of Cook by way of Bering's Straits, and of vessels sent on two successive seasons to Davis Strait to co-operate with him, satisfied the Admiralty of the day; and for forty years the North-West Passage was unheard of in the government bureaus.

In 1789 Sir Alexander Mackenzie, a member of the North-West Fur Company, trading from Canada, discovered the great river which continues to bear his name, and traced it to its termination in the Arctic Sea; and in 1790–3 the Hudson's Bay Company sent out Mr Duncan to seek a passage by following in the track of Middleton; but his crew mutinying when he had got as far as Chesterfield Inlet, compelled him to return. Lieutenant Kotzebue of the Russian imperial navy made a voyage, at the cost of Count Romanzoff, in 1815–17, from the Baltic to Bering's Straits, in which he discovered Kotzebue Sound, but added

[1] Matonabbee was much attached to the English, and when La Peyrouse attacked Fort Churchill, he offered to cut off the assailing party with his Indians. Hearne, who had charge of the fort, preferred surrendering without striking a blow, which Matonabbee took so much to heart that he committed suicide.

[2] Bering was a Dane, and his family retain the orthography we have adopted. (Bäer Nachricht, &c.)

Arctic Regions.

Arctic Regions.

nothing else to the surveys of Cook on that coast. This Russian enterprise, however, together with the publications of Dr Scoresby and the personal influence of Sir John Barrow, secretary of the Admiralty, incited the British government to undertake a new series of enterprises, which have resulted in the discovery of the entire northern coasts of the American continent and of the islands beyond it up to a high northern latitude. The annexed list[1] of the ships and overland expeditions connected with this movement is long enough to show the impossibility of describing the doings of each within the compass of a few pages; and we shall therefore confine ourselves to the simplest sketch of the actual geographical discoveries.

The Trent and Dorothea, sent out in 1818 to attempt the Polar route, failed, owing to damage received by the former in the ice; but the Isabella and Alexander, which took the route of Davis Strait, were more fortunate, in being able to return without injury to England before the close of the season. By this voyage Baffin's survey of the bay which bears his name was confirmed, and the various sounds that he had described were found in the exact positions he had assigned to them. Lancaster Sound was closed to Baffin by a barrier of ice, and this was the only inlet attempted by Captain John Ross, who sailed without impediment to Long. 81. 30. W., in Lat. 74. 3. N., a short way within its headlands, Capes Charlotte and Fanshawe. But his progress on so promising a course was suddenly arrested by the vision of a mountain barrier closing the bottom of the sound, seen by few or none in the ship except himself. Without ascertaining by a nearer approach whether the Croker Mountains were firm land or merely one of the atmospheric deceptions so common in those seas, he forthwith returned to England, tracing on his way the W. coast of Davis Strait; but too cursorily, and at too great a distance, to negative the existence of passages through that line of coast.

Doubts of the reality of the Croker Mountains being entertained by most of Captain Ross's associates, and the report of that officer not being thought conclusive by the Admiralty, the Hecla and Griper were despatched, in 1819, to clear up the matter, which they did triumphantly by sailing westwards to Melville Island. After being inclosed in the ice of Winter Harbour for ten months, and making new but fruitless attempts to penetrate the icy barrier to the westward, the expedition returned to England. The success of this voyage, so far exceeding every previous attempt, the preservation of the health of the crews during the long Arctic winter, and the perfection of the commanding officer's general arrangements, placed Lieutenant Parry at once in the van of Arctic discoverers; and he was speedily raised, amid the gratulations of his country, through the grade of commander to that of captain. Reckoning in round numbers the distance between Baffin's Bay and Bering's Straits at 110° of longitude,—viz., from 60° W. to 170° W.,—Captain Sir William Edward Parry explored his way up to Cape Dundas through 54 of these degrees, or nearly a half of the whole distance; and he saw on the verge of his western horizon, Banks' Land, 2½° farther off. He also laid down the chain of islands on the N. side of his track, with the openings between them, including the entrance of Wellington Channel, and on the S. side Regent's Inlet, North Somerset, and Cape Walker. By his subsequent voyages, enumerated in the table, he effected the surveys of the upper end of Regent's Inlet, and of the eastern side of Melville Peninsula from Repulse Bay to the Fury and Hecla Strait, leading into the above-named inlet; confirming completely the accuracy of Middleton's account of Repulse Bay. Finally, having found no navigable passage to the westward in those latitudes, he attempted, in 1827, to make the Polar voyage in boats, and actually reached Lat. 82. 40. 30. N., being the highest authentic position attained by any voyager.

At the same time that Sir Edward Parry was seeking a passage through the Arctic archipelago, Lieutenant (afterwards Captain and Rear-Admiral Sir) John Franklin was prosecuting the survey of the northern shores of the con-

[1] LIST OF MODERN NORTH-WEST VOYAGES.

1818	Trent	Comm. David Buchan.
	Dorothea	Lieut. John Franklin.
1818	Isabella	Capt. John Ross.
	Alexander	Lieut. William Edward Parry.
1819–1822	Overland (canoes)	Lieut. John Franklin.
1819–1820	Hecla	Lieut. W. E. Parry.
	Griper	Lieut. Mathew Liddon.
1821–1823	Fury	Comm. W. E. Parry.
	Hecla	,, G. F. Lyon.
1824	Griper	Capt. G. F. Lyon.
1824–1825	Hecla	Capt. W. E. Parry.
	Fury	,, H. P. Hoppner.
1825–1827	Overland and Boats	Capt. J. Franklin. Dr John Richardson.
1825–8	Blossom	Capt. W. F. Beechey.
1827	Hecla	Capt. W. E. Parry.
1829	Victory	Capt. John Ross. Lieut. James Clark Ross.
1833–1835	Overland and Boats	Capt. George Back.
1836	Terror	Capt. George Back.
1836–1839	Overland and Boats	P. W. Dease and Thomas Simpson, Esqs., Hudson's Bay Company.
1845–1850	Erebus	Capt. Sir John Franklin.
	Terror	,, Crozier.
1846–1847	North Pole (lugger)	Dr John Rae, Hud. Bay Co.
1848–1852	Plover	Capt. Thomas Moore.
1848–1852	Herald	Capt. Henry Kellett.
1848–1850	Nancy Dawson (yacht)	—— Shedden, Esq.
1848–1850	Overland (boats)	Sir John Richardson.
1849–1851	North Star	Master Saunders, R.N.
1849	Advice (whaler)	Dr R. A. Goodsir.
1850–1855	Enterprise	Comm. Robert M'Clure.
	Investigator	Capt. Richard Collinson.
1850–	Resolute	Capt. Horatio Austen.
——	Assistance	Commander Ommaney.
1850–1851	Lady Franklin	Master Wm. Penny.
	Sophia	,, Alex. Stewart.
1850–1851	Felix (yacht)	Capt. Sir John Ross.
1851	Dædalus	Capt. G. G. Wellesly.
1851–1852	Prince Albert	William Kennedy, master. Lieut. Bellot.
1852	Amphitrite	Capt. Chas. Frederick.
1852	Isabel	Comm. E. A. Inglefield.
1852–1855	Plover	Comm. Rochfort Maguire.
	Boat	Dr M'Cormick.
1853	Phœnix	Capt. E. A. Inglefield.
1852–1854	Assistance	Capt. Sir Edward Belcher, C.B.
	Resolute	Capt. H. Kellett, C.B.
	Pioneer	Lieut. Sherard Osborn.
	Intrepid	Comm. M'Clintock.
	North Star	Comm. W. J. S. Pullen.
1853	Breadalbane	Lieut. Fawckner.
1853	Diligence	Lieut. Elliott.
1853	Rattlesnake	Comm. H. Trollope.
1853	Boats	Dr John Rae, Hudson's Bay Co.
1854	Phœnix	Capt. E. A. Inglefield.
1857–1859	Fox	Capt. M'Clintock (not yet returned).

tinent. In 1819–1822, after travelling overland from Hudson's Bay to the Coppermine River of Hearne, he descended to the mouth of that stream, and traced the coast of Cape Turnagain through nearly 7° of longitude; but owing to the deep indentations of the coast-line, having actually performed a sea voyage in canoes of 550 geographic miles in the seven weeks during which the navigation was open. In 1825–7 Franklin descended the Mackenzie, and traced the coast westward to Return Reef, 158. 52. W. Long., or about 22½° from the principal mouth of the Mackenzie. In connection with this expedition, Captain Beechey, in the Blossom, had gone through Bering's Straits, and by means of his boats, had explored the American coast to Point Barrow, 120 miles beyond Cook's Icy Cape, and only 160 miles distant from Franklin's Return Reef.

While Franklin was employed to the westward of the Mackenzie, Dr John Richardson was tracing the coast between that river and the Coppermine, comprising, to Cape Krusenstern, his most easterly point, 21 degrees of longitude in a direct line, having seen in his passage through Dolphin and Union Strait a considerable portion of Wollaston Land. This officer also circumnavigated Great Bear Lake, and ascertained the geographical positions of its headlands, being aided in the sea voyage and in part of the lake survey by Lieutenant Kendall. In Franklin's two voyages, therefore, including the operations of the detachment under Dr Richardson, the Arctic coast was surveyed to the extent of 50 degrees of longitude, making, with the portion examined by Beechey, more than half the distance from Bering's Straits to Baffin's Bay, and considerably overlapping Parry's tract, but in a lower latitude; his surveys, moreover, included a very long inland navigation, comprising Winipeg, Athabasca, Great Slave and Great Bear lakes, with the Mackenzie and Coppermine rivers. A *passage* lying N. and S., connecting the tracks of Parry and Franklin, would have solved the North-West problem; as would also an easterly continuation of Franklin's discoveries.

In the years 1829–33, funds having been provided by the munificence of Sir Felix Booth, Bart., Captain Sir John Ross, accompanied by his nephew, Lieutenant James Clark Ross, passing through Lancaster Sound, surveyed the west side of Regent's Inlet, Lieutenant Ross carrying on the survey on foot southwards to Lord Mayor's Bay, and westwards to the western side of Boothia, the magnetic pole, and Cape Nikolai; also rounding Maty Island, and tracing the northern coast of King William's Island. This voyage was remarkable for the number of winters spent in a high latitude; and fears being at length raised for the safety of the party, an expedition was organized for their rescue, commanded by Captain (now Rear-Admiral Sir) George Back, funds being raised by public subscription. During the prosecution of his humane enterprise this officer surveyed the east end of Great Slave Lake, previously unknown, and the Great Fish River, to its estuary, bounded by Cape Britannia and Point Richardson, but still leaving a small space incomplete between his northern limits and the southern ones of Lieutenant Ross. Having been made acquainted, on the eve of his summer voyage, with Sir John Ross's safe return, Captain Back's further extension of the voyage was no longer desirable except for geographical purposes.

To complete the intervals left between these surveys of the northern coasts of the continent, the Hudson's Bay Company employed in 1836–39 one of their chief factors, P. W. Dease, and Mr Thomas Simpson, a junior officer of great activity and enterprise. Proceeding first from the Mackenzie, they succeeded in reaching Point Barrow, thus finishing the discovery of the coast-line on that side, and then, after passing two winters at the north end of Great Bear Lake, they descended the Coppermine, and sailing eastward far beyond Franklin's Point Turnagain, crossed the estuary of Back's Great Fish River, and traced the coast some way farther to the eastward; but owing to the rapid approach of winter, and strong contrary winds, they were under the necessity of turning back without having actually reached Captain Ross's discoveries in the peninsula of Boothia. On the homeward voyage to the Coppermine, Simpson, on whom the geographical survey devolved, laid down most of the south coast of Victoria Land. A small part of this extensive island had been seen by Franklin's party from the lofty summit of Cape Barrow, but it was somehow omitted from his map; and Simpson duly exercised the right of a discoverer by naming it, though, as it is now known to be continuous with Wollaston Land, this appellation has the priority.

In 1845–7 Dr John Rae, in the employment of the Hudson's Bay Company, by a most hazardous enterprise considering the means at his command, and after wintering in Repulse Bay, where for ten months the lives of his party were dependent on his personal skill in the chase, surveyed the bottom of Regent's Inlet up to Fury and Hecla Strait of Parry, on the east, and on the west to James Ross's Lord Mayor's Bay, thereby ascertaining that an isthmus 4 degrees of longitude wide interposed between the bottom of Regent's Inlet, or the Gulf of Boothia, as it was re-named by Ross, and the eastern part of the sea explored by Simpson.

At the beginning of this period,—that is, in 1845,—the Admiralty, after having for a time intermitted the prosecution of a North-West Passage, commissioned the Erebus and Terror to renew the attempt under the command of Capt. Sir John Franklin, who had recently returned from Tasmania, of which colony he had been lieutenant-governor for five years. The two ships were made as strong as the skill of the shipwrights, perfected by previous experience, could effect, and were crammed full of stores and provisions, not, however, amounting in all to three years' consumption, at full allowance. This expedition was seen in Davis Strait, in the same year, proceeding prosperously; but three years having elapsed without further intelligence, active measures were taken by the Admiralty in 1848 for tracing and relieving it.

Searching expeditions.

The Herald and Plover were despatched, towards the close of the year just mentioned, to Bering's Straits, with orders to remain there, and afford aid to the expedition, should it have succeeded in accomplishing the passage. In 1849 Captain Kellett, in the Plover, discovered a group of high islands in Lat. 71. 20. N., near the meridian of the Asiatic Cape North; also the loom of distant mountains, probably part of the chain which Baron Wrangel mentions as visible at times from Jakan.

Sir John Richardson, accompanied by Dr Rae, left England early in 1848, and having landed at New York, proceeded without delay to the head waters of the Mackenzie, where, having joined their boats that had been sent out to Hudson's Bay in the previous summer, they descended the river just named, and minutely examined the coast eastward to the Coppermine, which they ascended and fixed their winter quarters at the north end of Great Bear Lake. Lieutenant Pullen, despatched in the succeeding year (1849) from the ships in Bering's Straits, passed in boats along the coast from Point Barrow to the Mackenzie, but neither he nor Sir John Richardson found any vestiges of Franklin's ships, nor did they receive any intelligence of them from the Eskimos. The search was at the same time proceeding by way of Lancaster Sound under the direction of Captain Sir James Clark Ross. This officer wintered with his ships at Leopold Harbour, on the extremity of North Somerset, having previously examined various points on both sides of Barrow's Strait. In the spring he sent exploring parties in several directions; and himself headed a sledge expedition along the west side of North Somerset, down to Lat. 72. 38., within a short distance of Bellot Strait, which is said to separate North

Somerset from Boothia Felix. No traces of the Erebus and Terror were found, though it is now known that at that very time they were on or near the west coast of Boothia, or off King William's Island. Next summer Sir James, on leaving Port Leopold for the purpose of continuing the search, was suddenly inclosed in a pack of drift ice, and carried helplessly out of Lancaster Sound into Davis Strait. His ships were not released until the 25th of September, when the navigation for the season having come to a close, he reluctantly bore up for England. The want of success of the land and sea searching expeditions did not diminish the desire of the people of England to carry succour to their countrymen imprisoned in the ice; on the contrary, the popular feeling raised by the devoted exertions and pathetic appeals of Lady Franklin was expressed in terms that would admit of no denial. The Admiralty accordingly prepared again for the search on a most extensive scale, regardless of expense. The Enterprise and Investigator (late Ross's ships) were despatched on the 20th of January 1850, to enter the Arctic Sea by way of Bering's Straits, and to pursue the search eastward from thence. In the same year a large force was sent to Lancaster Sound,—viz., Captain Horatio Austen, with two stout vessels and two steam-tenders under his command; Captain William Penny, of the mercantile navy, with two vessels, also under the directions of the Admiralty; Captain Sir John Ross in the Felix schooner, equipped principally by the Hudson's Bay Company; the Albert, Commander Forsyth, sent out at the expense of Lady Franklin; and two vessels from the United States, under the command of Lieutenant De Haven, and equipped by the munificence of Mr Grinnell, a New York merchant. Such a squadron, though it did much, might, if it had been well distributed, have effected more; but, as it happened, they all, with the exception of the Albert, pressed on directly to the westward, and at the close of the season were congregated on the coast of North Devon. The Admiralty showed a want of judgment in sending officers of the royal navy and of the merchant service with independent commands to the same quarter, and prepared the way for misunderstandings and bickerings which did not fail to follow. Captain Ommaney, on the 23d of August, in one of Austen's tenders, found traces of one of Franklin's encampments on Beechey Island, but hastened on after his commanding officer without exploring the island further. The American expedition also landed at the encampment; but it was reserved for Captain Penny, who made a more leisurely and extensive search, to discover Franklin's winter quarters, and the tombs of three of his men, who had died early in 1846; yet no memorial was found of Franklin's proceedings, nor any indication of the course he intended to pursue on leaving that harbour. The American vessels, when the navigation was about to close, bore up to return home, when, being caught in a floe, they were carried by the winds and currents first into Wellington Sound, by which they became the discoverers of Grinnell Land, and the lower part of that channel; next into Baffin's Bay, and there, and in Davis Strait, they remained shut up in the ice, drifting all the time to the southward, until the approach of the following summer released them. Captain Penny during the winter explored both sides of Wellington Sound with his sledge parties in the spring, to beyond the straits formed by the chain of islands named by him Dundas and Baillie Hamilton. Captain Austen, also, by a skilfully combined system of sledge expeditions, examined the north shore of the sea named in the Admiralty charts Melville Sound; also the openings northwards on each side of Byam Martin Island, which were followed for some way. He likewise traced the coast of Prince of Wales Land on the south of Melville Sound, down to the 72d parallel of latitude on the west, and to the 73d parallel on the east. This survey embraced a visit to Cape Walker, which is the eastern extremity of Russell Island. The examination of this line of coast was most important, as it was towards Cape Walker that Franklin's instructions directed him to go, but no indications were discovered of the missing ships having touched at any part of the coast thus minutely explored. To Captain Austen the merit is certainly due of having brought the sledge equipments to a degree of efficiency that they had not previously attained on the ice of the Arctic Sea, and he was well seconded by his officers and men, who made journeys remarkable both for the number of days that they were absent from the ships, and for the great extent of coast that was traversed. This year, also, the North Star, Master Saunders, carrying stores to Lancaster Sound, was driven by stress of weather into Wolstenholme Sound, and wintering there, surveyed that indentation of the Greenland coast.

On the return of the various ships employed in Lancaster Sound to England, at the close of the summer of 1851, complaints were made by Captain Penny that he was prevented from proceeding as far up Wellington Sound as he could have done, had he received the assistance that he asked from Captain Austen: the public press took up his cause warmly; and many writers, led away by their imaginations, expressed their opinions that Franklin had sailed far north into a Polynia, or open Polar sea, the existence of which was supported by plausible reasons. This line of argument, perseveringly urged, had an injurious effect on the future arrangements for continuing the search; and notwithstanding Franklin's known strict adherence to orders, which, as we have said, were to get to the southward from the neighbourhood of Cape Walker, search in that direction was comparatively neglected by the ships which left England in 1852, being pursued only by Lady Franklin's schooner the Albert, and by her but for a short way.

The preparations in 1852 were more complete than in any previous year, and Sir Edward Belcher sailed in command of a most thoroughly efficient squadron. Pursuing the plan that had been recommended to the Admiralty by General Sabine, and practised by Captain Austen, of employing the ships merely as a base of operations, and seconded by able officers already trained to conduct sledge parties, Sir Edward explored the upper outlets of Wellington Channel, and mapped the archipelago of Parry's Islands, from Prince Patrick Island, on the west, to Polynia Islands and North Cornwall, not far from the 78th parallel, on the north, and nearly to Jones' Sound on the east. The lower part of this sound had been entered by Captain Austen on his homeward voyage; Wolstenholme Sound was fully explored by Master Saunders; and at this period three of Baffin's five sounds had therefore been partially or fully examined. The other two, Whale Sound and Smith's Sound, were also looked into this year (1852) by Commander Inglefield, in charge of Lady Franklin's screw-steamer Isabel.

Lady Franklin's other vessel, the Albert, which left England in 1851, wintered that season in Regent's Inlet, and Mr Kennedy, her commanding officer, aided by the gallant Lieutenant Bellot of the French navy, a volunteer, made a winter journey of sixty-three days, in which they discovered a strait to the north of Boothia Felix, to which the name of Bellot was given; then crossing and re-crossing Prince of Wales' Land diagonally, they touched at Cape Walker; and after rounding the end of North Somerset, regained their vessel on the 30th of May 1852. The great length of this journey, performed in the severe cold of the early months, is highly creditable to the ability and endurance of the party; but had it been directed to the examination of the lower end of Peel Sound, and the channels round King William's Island, it is more than probable that the fate of Franklin's party would then have been ascertained by the discovery of the remains of the ships, though two years too late to have found any of the crew surviving.

Mr Kennedy did not know that the north part of Peel Sound had been surveyed by Captain Austen's officers; and on looking in that direction from the west end of Bellot Strait, the islands appeared like a continuous barrier denying a passage to ships. He therefore thought it needless to search the southern part, though that was more open. Lieutenant Bellot was unfortunately drowned after the breaking up of the ice in Wellington Sound, to the great regret of all who knew him.

In 1851 Dr Rae, who, in 1850, had been frustrated by ice in an attempt to reach Wollaston's Land in a boat, proceeded thither from the Coppermine river on foot before the opening of the navigation, and traced the coast from Simpson's most westerly point of Victoria Land to Prince Albert Sound of Wollaston Land, proving that Victoria and Wollaston are parts of the same island. Crossing again to the Coppermine, he rejoined his boat, descended the river in her, and steering to the eastward through Dease Strait, turned towards the north, round the east end of Victoria Land, as far as Pelly Point. The state of the ice prevented him from proceeding farther than Lat. 70. 2. 30. and Long. 101. 18. W., in that direction, or from crossing over to King William's Island, which he was very desirous of doing. Previous to turning back, he picked up a bit of the stanchion of a ship's ice-plank, doubtless a fragment of the fittings of the Erebus or Terror.

The Enterprise and Investigator, commissioned in 1849 to take part in the search for Franklin by way of Bering's Straits, sailed from England in January 1850, the former under the command of Captain Richard Collinson, C.B., the latter under that of Commander Robert Le Mesurier M'Clure. The latter was fortunate in being able to pass through Bering's Straits a year before his senior officer, and, pushing along the north coast of the continent in the summer of 1850, discovered the south end of Banks' Land, and the strait between that island and Wollaston or Albert Land, for the parts of the coast bearing the latter name are continuous with Victoria Land. His officers surveyed the north shore of Wollaston Land as far eastward as Point Reynolds, which is situated in the same parallel of latitude with Osborn's extreme point, and at the distance of 4° of longitude, or about 65 geographical miles. The existence of a passage in this unexplored interval, through which Franklin's ships may have gone, if they did not pass southward by Peel's Sound, is still an open question. Captain (Sir Robert) M'Clure also surveyed the west coast of Albert, or rather Wollaston Land, down to Prince Albert Sound; and Lieutenant Haswell reached the north side of that inlet exactly ten days before Dr Rae arrived on its southern shore, as already mentioned. Failing in an attempt to enter Melville Sound from Prince of Wales' Strait, Captain M'Clure circumnavigated Banks' Land by the west, and the Investigator, after narrowly escaping shipwreck, was finally shut up in the Bay of Mercy at the northern point of the island. Here, in 1853, the ship was abandoned, and the debilitated crew, travelling over the ice to Dealy Island, were received into the Resolute, and tenderly cared for by Captain Kellett. No one can deny the merit of great nautical skill, resolution, and perseverance to the commanding officer of the Enterprise, who was admirably supported by his officers and crew, nor that the parliamentary grant and other rewards which they received were fully merited; but it is surely a misnomer to describe this voyage as the "Discovery of a North-West Passage." Sir Edward Parry alone, of several navigators from the eastward, was able to conduct his ship as far as Cape Dundas, from whence he looked over an *impenetrable* waste of ice, his view being bounded by the land rising over the Bay of Mercy. From that bay Sir Robert M'Clure and his followers travelled eastwards on foot, and the space intervening between the points reached by his ship and Parry's has never been crossed even by a boat, nor seen in a navigable condition. Sir Edward Parry was stopped by fast ice in the summers of 1819 and 1820; Sir Robert M'Clure found it equally impassable in 1850–51 and 1852; Captain Collinson adds the weight of his testimony to the same fact; Captain Austen, in 1850–51, was unable to advance westward beyond Cape Cockburn; and Captain Kellett got no farther than Dealy Island.[1]

To Captain Collinson belongs the credit of having made the longest voyage along the northern shores of America in a ship. A year later than M'Clure in getting round Cape Barrow, like him he failed in passing beyond the northern end of Prince of Wales' Strait; and after wintering on the west side of Wollaston Land, he carried his ship, in the summer of 1852, through Dolphin and Union straits eastward to Cambridge Bay, on the south side of Victoria Land. His sledge parties came upon the traces of Dr Rae, and learnt from one of his records that he had already examined that coast, but were not able to extend the search farther than Gateshead Island, or 20 miles beyond him. Between this and the 72d parallel of latitude, where Kennedy crossed Peel Sound, there is a space of 92 geographical miles not yet explored, in which, as we have already said, a passage from Osborn Bay, at the south side of Melville Sound, *may* exist. The west shore of Boothia Felix, from Cape Nikolai of James Ross to Bellot Strait is also unknown to the extent of about 90 miles; but that there is a strait here continuous with Peel Sound, there can be no reasonable doubt, and it has been named Victoria Strait in Kennedy's account of his voyage. Captain Collinson's voyage, though the longest in the Arctic seas, was, owing to his late arrival in the field of search, productive of but few additions to the map. The Eskimos who visited his ship in Cambridge Bay, had in their possession a piece of an iron bolt, and a fragment of a hutch-frame, which are believed to have come from the Erebus or Terror. A deficiency of coals induced Captain Collinson to return by the way he came, instead of spending another year in forcing a passage to the eastward, and after a third winter in the Arctic seas, he brought his ship safely to England.

In 1854 Dr Rae returned to Repulse Bay for the purpose of ascertaining beyond cavil the continuity of the neck of land that separates Regent's Inlet, or the Gulf of Boothia, from the bay into which the Great Fish River falls, and also in the hope of carrying the search for the Erebus and Terror along the west coast of Boothia up to Bellot Strait. Part of this design he effected, establishing the absence of a passage through the isthmus; and crossing from Pelly Bay to Inglis' Bay, he traced the west side of Boothia Felix until he connected his surveys of that coast with Sir James Ross's in 1830. Continuing his route northwards to a little beyond Cape Suisse, he was there compelled to turn back by the state of the weather, the failure of his commissariat, and the sufferings of one of his crew from frost bite. By this journey, however, in combination with his voyage of 1851, he ascertained the insular character of King William's Land, though from its distance he could not lay down all its coast-line. From a party of Eskimos that he met on this journey, he learnt that in the spring of 1850 another small party of that nation were killing seals on the north shore of King William's Land, when they saw about forty white men travelling to the southward along the west side of the island, and dragging a boat and sledges. None of the white men could speak Eskimo so as to be understood, but by signs they intimated that their ships had been crushed by ice, and that they were going where they expected to find deer to shoot. All the men, with the exception of one officer, were hauling on the drag-ropes, and were looking thin. The Eskimos sold them a piece of seal. At a later period in the same season, but before the ice broke up, some thirty dead white men were discovered on the continent a long day's journey to the west of the Great Fish River, and five more bodies lay on an adjoining island. Some of this unfortunate party must have survived till the end of May or beginning of June, when wild fowl arrive, as the neighbouring Eskimos heard shots at that period, and feathers of geese and fresh bones of birds were found by the natives at the spot. From the Eskimos Dr Rae purchased so many pieces of silver plate, and such a variety of other articles that were recognised as having been the property of officers of both ships, as to lead to the conclusion that the party who there perished were the sole remnants of the two crews. None of the Eskimos with whom Dr Rae spoke had seen the white men alive or dead, and the information they gave him, through an able interpreter, had been got by them from others of their nation.

---

[1] Sir Edward Parry says,—"It now became evident, from the combined experience of this and the preceding year, that there was something peculiar about the south-west extremity of Melville Island, which made the icy sea there extremely unfavourable to navigation, and which seemed likely to bid defiance to all our efforts to proceed much farther to the westward in this parallel of latitude." (*North-West Passage*, 1819-20, p. 241.) Captain Osborn, in his narrative of M'Clure's voyage, also remarks,—"The heavy pack of Melville Strait, lying across the head of the channel, was supposed to be the reason of the ice of Prince of Wales Strait ceasing to move on to the north-east; and the *impassable* nature of the pack in the same direction in the following year confirmed this hypothesis." (P. 114.) A writer in the *Natural History Review* for April 1858 attributes the fixity of the packed ice in this quarter to the meeting of the Atlantic and Pacific tides in Banks' Strait.

In consequence of the intelligence brought to England by Dr Rae, the Hudson's Bay Company, at the instance of government, despatched Mr Anderson, one of their chief factors, down the Great Fish River in 1855, to visit the spot where the party had perished, and to communicate with the neighbouring Eskimos. Unfortunately, no interpreter could be procured, there being in fact none within 2000 miles; and the only conversation Mr Anderson could carry on with the Eskimos he saw at the mouth of the river, was by the unsatisfactory medium of signs. From them, however, he obtained many additional articles found on the deceased; and on Montreal Island he discovered the spot where the boat had been broken up by the natives for its wood and nails. By expressive and unmistakeable pantomime, the Eskimos told him that the white men had died of hunger. A minute and patient search of the whole peninsula of Point Ogle, and an adjacent island to the westward, as well as of Montreal Island to the eastward, revealed to him neither books nor scraps of paper, nor arms, nor a single human bone or grave. His supposition, that all the dead were concealed by drift sand can scarcely be acceded to; and the more obvious conclusion is, that he had not arrived at the exact place of the death of the party. The fact of an enfeebled party having dragged a ship's boat to Montreal Island leads fairly to the inference, that no land was crossed by them, and that their weary journey was wholly over ice. Their ships must have been abandoned in the unexplored space of about 90 miles diameter above mentioned, and their journey southward discovered an ice-bound strait forming a link or a barrier (according as it is permanently closed or occasionally open) in the North-West Passage, some months earlier than Sir Robert M'Clure crossed one of a similar character in a higher latitude. A regard for the fame of her gallant husband and his brave companions has led Lady Franklin to seek for written records of this discovery by a further search, and perhaps the humane promptings of a hope surviving in her breast, though extinguished elsewhere, that even yet relief may be carried to some forlorn survivor of the catastrophe.

Government having declined any further proceedings, Lady Franklin, in 1857, placed the Fox yacht under charge of Captain M'Clintock, who volunteered once more to encounter the hardships and hazards of an Arctic search. He sailed, with a crew of twenty-four, including Anton Christian, a Greenland Eskimo, intending to seek the remains of the ships in the unexamined space already several times alluded to as lying to the N. of King William's Island. That summer he was unable to cross Baffin's Bay, but being caught in the "middle ice," he drifted with it to the southward all the winter, during which northerly winds blew almost continuously. On being released in the summer of 1858, with his crew in good health and spirits he touched on the Greenland coast for supplies, and afterwards gained the west side of the bay, being, when last heard of, near Pond's Bay.

The narrative of this melancholy search, which has added so largely to the geography of the Polar seas, has led us to postpone the notice of an enterprise the most remarkable of all, and prior in point of time to some of those above mentioned. We allude to Dr Kane's wonderful exploration of Smith's Sound. That he should have sought the Erebus and Terror at all in such a direction is due perhaps to the adoption of the Russian theory of a *Polynia*, and the arguments of a party expounded in the periodical press, forgetting that Franklin would unquestionably pursue, if able, the course pointed out by his instructions, of penetrating by the first opening he could find near Cape Walker to the open channel along the continental shore. Be this, however, as it may, Dr Kane, having chosen his line of search, pursued it unflinchingly under difficulties, arising from the severity of the climate and scantiness of means, that would have appalled and driven back any one not possessed of that fixedness of purpose and fertility of resource which formed parts of his character. His voyage commenced in 1853, and he reached home, after passing two winters in Smith's Sound, and finally abandoning his ship, in 1855. According to Dr Kane's view of the structure of the coast, Greenland terminates at Cape Agassiz by the stupendous Humboldt Glacier, issuing from a *mer de glace* a little above the 79th parallel; this glacier, 60 geographical miles wide, being the boundary between it and Washington Land. The highest point of Washington Land is Cape Constitution, in Lat. 80. 56. N. This is not far S. of the land seen by Hudson in 1607, to the W. of Spitzbergen, which may therefore be considered as part of the eastern coast of Washington Land. On the western side of Smith's Sound, the extreme point seen by Dr Kane's party is Mount Parry, which was laid down approximately by reckoning in Lat. 82. 30. N., and Long. 66. W., or 82. 14. reduced lat. Ross's Inlet, the extreme rock of the Seven Islands, and the most northerly land previously correctly known, is 100 miles more to the S.; and even the somewhat conjectural position of Hudson's northernmost point falls short of Kane's Mount Parry. Smith's Sound, or Kane's Channel, as it is otherwise named, is 33 geographical miles across at its narrowest places. During Dr Kane's residence in Smith's Sound, an unbroken bridge of ice remained across the sound up to the 81st parallel of latitude. Northwards of this there was open sea between Washington and Grinnell lands, whose waters had a temperature of +36° F., while the thermometer marked −60° F. of atmospheric cold.

Physical Geography of the Arctic Polar Basin.

The residents on the shores of Hudson's Bay are aware that pools of water, recognisable from a distance by the mist rising from them, exist in the depth of winter amid the ice of that sea. Sir Edward Parry and other voyagers observed similar pools in higher latitudes, with Dovekies lingering in them all the winter; and Baron Wrangell and Lieutenant Anjou, in attempting to travel northwards over the ice from

Physical aspects.

the estuaries of the Lena and Kolyma, were stopped by open water. Middendorf also, in 1843, found an open sea at Cape Taimura. It is not surmised that the small pieces of water seen by Parry were otherwise than accidental,—that is, not having a fixed locality, but recurring in different situations in different winters; and indeed the winter drift of large ice-fields experienced by Lieutenant De Haven's vessels, by the Resolute after Captain Kellett had reluctantly obeyed the command to abandon her, and last year by Captain M'Clintock, indicates that open spaces must be left by the removal of such extensive fields. That this drift is normal, and not the casual effect of winds in one or two exceptional seasons, is proved by the annual descent in winter of ice-fields and large bergs down Davis Strait, and the similar route of several whalers that have passed a winter in the ice. But the Russian geographers and others have conjectured that, in addition to the comparatively small pools observed in the accessible parts of the *Ledovintoe More*, or Frozen Ocean, there exists at all seasons, nearer the Pole, a *Polynia*, or open sea of warmer water, whose verge was reached by Wrangel, and more recently by Kane.

Ocean currents.

Lieutenant Maury, reasoning from various facts which he adduces, infers that there must be an under-current in Davis Strait from the S., which rises to the surface somewhere in the N., and there produces an area of warm water of *considerable* extent, tempering the climate of high parallels, and being one of the beautiful compensating actions of nature. Baër also takes it for granted that there must be an under-current towards the S. in Bering's Straits, resulting from the superficial one in the opposite direction.

Sir Edward Parry, when he reached the parallel of 82. 45. N. in his memorable boat voyage from Spitzbergen, had to contend with a current setting to the S. at the rate of more than 4 miles a day, which was increased when a northerly wind blew. The natives of the E. coast of Greenland are familiar with the drift of what they call the "great ice," which, coming down from the N., often fills the strait between Greenland and Iceland, and is probably an extension of the drift experienced by Parry. At Cape Farewell the great ice occasionally forms a belt from 120 to 160 miles wide, but in general only a narrower stream, known to the whalers as the Cape Farewell ice; and in some seasons the navigation at that extremity of the land is quite free from port to port. Part of the great ice is deflected to the N. along the W. coast of Greenland, probably by the action of the under-current spoken of by Lieutenant Maury. The main surface current, however, sets out of Davis Strait, and the sounds connected with it, both in summer and winter. On the disruption of the ice off Meville Island, Parry saw it move to the eastward; and it took a similar course many years afterwards, when Captain Kellett wintered at Dealy Island. Sir James Ross's voyage of 1849 was also brought prematurely to an end by drift ice taking in summer a course out of Lancaster Sound nearly identical with the drift of the American ships in winter.

At Bering's Straits, on the contrary, the current, according to general testimony, sets in to the N.; and Commander Maguire, the latest of the Arctic voyagers in that quarter, calls it strong, and of great assistance to him in his passage northwards against contrary winds. He mentions that the whalers, even with favourable winds, were obliged to warp when going against the current. The same current, setting to the northward and eastward, was powerful off Point Barrow.

In the narrow seas bounding the American continent between Point Barrow and Great Fish River the tides are perfectly regular, though of small velocity, and producing but little rise of water, rarely amounting to 4 feet. Some of the late Arctic navigators have thought that they perceived a prevailing current setting to the eastward on this coast. Between the Mackenzie and Coppermine rivers Sir John Richardson found the flood-tide setting to the eastward; but on an indented coast the real direction of the tide can scarcely be ascertained by a passing voyager; and he remarks that a gale of wind produces a greater rise of water on that coast than an ordinary spring-tide,—three days of a strong north-wester being sufficient to flood for many miles the low-lying meadows east of the Mackenzie, and deposit long lines of drift timber at the foot of the rising grounds. In the Strait of the Fury and Hecla the tides rise 9 feet; but the stream of the current was to the eastward throughout the twenty-four hours, with in-shore eddies running the other way. This easterly current was as much as 4 miles an hour at times;[1] and the observers thought that in the summer season it was so much stronger than in the winter as to mask the small westerly stream of the ebb-tide. From Dr Sutherland's register of tides, kept near Cape Hotham, the western portal of Wellington Sound, we learn that the rise and fall varied from less than a foot to a little more than 6 feet. At Cape Becher, on the N. side of the upper extremity of Wellington Sound, the flood-tide flowed about nine hours, and the ebb only three, the fall of tide being rapid. The strength of the current, according to some of Captain Penny's officers, was 4 miles an hour. Farther to the N. (on the 77th parallel) Sir Edward Belcher observed the *ebb* running strong to the E. towards Jones' Sound. As this was an isolated observation, it may be that the ordinary current setting out of the Polar Sea overpowered the feeble westerly ebb-tide, as in the preceding instance. In this quarter also the rise of spring-tides was 7 feet, and that of the neaps 2. In Prince of Wales' Strait the flood came from the S.; and M'Clure ascertained the rise and fall to be about 3 feet at spring-tides, but scarcely perceptible at the neaps.

Lieutenant Maury affirms that a tidal wave cannot be propagated through a barrier of ice 80 or 100 miles wide, and that the ebb and flow of the iceless sea discovered by Dr Kane under the 82d parallel must have been the movements of a Polynian tide generated about the North Pole. The Eskimos reported to Sir Robert M'Clure the existence of an unbroken barrier of ice of unknown width, extending westward from Parry's Island to the meridian of Point Barrow, at the distance of 30 or 40 miles from the continent. This leaves too narrow a space for the generation of a tide, if Maury's opinion be well founded; and the origin of the coast tide must in that case be sought for elsewhere.

Middendorf records a tidal rise of 36 feet in Taimur Bay.[2] If the gulf-stream doubles the extremity of Norway, as Lieutenant Maury's chart indicates, a body of comparatively warm water may strike against the North-East Cape of Asia, raising the flood to the height mentioned by Middendorf, and be deflected into the Polar basin round that far-projecting promontory. That a current sets in that direction along the western shores of Novaya Zemlya as far as Cape Nassau, has been ascertained by Admiral Lutke. Henry Hudson also, at a much earlier date, experienced the same current, which drifted his ship to the N. in a calm. Martens could not detect an ebb and flow of tide at Spitzbergen; nor could Barentzoon in the sea of Kara, or, as it is called from its calmness, Marmora, but he found the height of water at its entrance or *waygatz* to be largely influenced by the wind. Our information, therefore, respecting the movements of the Arctic Sea tends to show that warmer currents from the Atlantic and Pacific set round the North-East Cape of Asia, and also into Bering's Straits; while there is an outward flow, carrying with it much ice, between Spitzbergen and Greenland, as well as out of Davis Strait and down Fox's Channel. How far the under-currents spoken of by Baër and Maury operate in preserving the level is not so apparent. Maury considers one of the causes of the gulf-stream to be the increased gravity of the water resulting from tropical evaporation. In like manner, the freezing of the sea within the Arctic Circle, by precipitating the saline ingredients, must augment the gravity of the deeper unfrozen water; while the lighter surface water, freed from salt, is carried southwards in form of ice. Wrangel informs us that the Great Polynia is from 16 to 18 English miles to the N. of Kotelnoi and New Siberia, and keeps at the same distance from the continent of Asia between Cape Chelagskoi and Cape North.[1] In its vicinity northerly winds always enveloped his party in damp air. During the summer the current between Svatoi Noss and Kolintschin Island is from E. to W., or towards Bering's Straits, and in the autumn from W. to E. A current to the S.E., which prevails in spring, is attributed by Wrangel to the N.W. winds of that season.

Winds.

Mr J. H. Coffin, in a treatise published in the sixth volume of the *Smithsonian Contributions to Knowledge* (1854), places a meteorological pole in Lat. 84. N., Long. 105. W., and states that it is encircled by a zone, 23½ degrees in breadth, of westerly or north-westerly winds; encompassed on the south, between the parallels of 60. and 66. of N. Lat., by a belt of easterly and north-east winds, as indicated by observations made at Great Bear Lake, Great Slave Lake, Fort Enterprise, two stations in Greenland, and one at Reikiavik in Iceland. Lieut. Maury's wind-chart also marks the prevailing direction of the winds in the polar basin and northern seas as being westerly, but does not indicate the easterly encompassing belt of Coffin. Baron Wrangel observes that in Arctic Siberia, though the south-east winds prevail in summer, the north-west winds are most frequent, taking the general yearly average, and are especially common in the winter time; they are cold winds in summer, and bring snow-storms in winter. The south-west wind is, however, the most piercing to the sensations in the winter, and on that account receives the name of *Shalonik* from the native Siberians. Captain M'Clintock reports that during his eight months' drift in Davis Strait the wind was northerly. At Fort Confidence, on Great Bear Lake, for seven months of winter in 1848–9, the mean direction of the wind was from S.E. ½ E., the southing becoming more decided as the spring advanced: this observation, made within the verge of the Arctic Circle, being at variance with the general position laid down by Mr Coffin. The pressure of the atmosphere at that place was greatest when the wind was S.E., decreased greatly with a due south or due east wind, and was least when the wind blew from any point to the northward of east. The force of the wind was least in mid-winter; and from December to March, both months inclusive, calms were very frequent, but became rare in April. The sky was comparatively cloudy in October and November; remarkably clear in December and the succeeding four months. In the summer of 1848 little or no rain had fallen.

The theory of opposite aërial currents, which are such important agents in transferring heat, was considered by Professor Leslie to lead theoretically to the same conclusions, with respect to the gradations of temperature in different latitudes, as the empirical formula of Meyer, which represents the mean heat at the sea-level as proportional to the sine of twice the latitude; but Leslie erred in stating the mean temperature at the Pole to be 32° or 28° F.; and on the observations of Arctic voyagers proving this to be greatly above the truth, he was led to assert that there was some latent material inaccuracy in their thermometrical records. That there were in fact great defects in the graduation of the alcoholic thermometers formerly in use, is now well ascertained, but this is remedied by the employment of absolute alcohol only, and fixing the point of − 40° F. by freezing large masses of mercury. Thermometers are now tested for the Board of Trade at the Kew Observatory; and every Arctic traveller may find the error of his thermometer for himself by plunging the bulb into freezing mercury as soon as the temperature is sufficiently low. In consequence of this easily-applied test having been neglected, there is generally error more or less in the earlier thermometric records of the recent Arctic voyages, but not nearly to the extent which Professor Leslie supposes.

The able philosopher just named also informs us that the limit of perpetual congelation forms a curve which is nearly the same as the *companion of the cycloid*, bending gradually from the equator, reverting its flexure at the 45th parallel, and grazing the surface of the sea at the Pole; the mean height of eternal frost under the equator, and at latitudes 30. and 60. being respectively 15,207, 11,484, and 3,818 feet. He is probably correct in stating that the snow-line keeps near the sea-level in the north polar regions, though the *mean* temperature of the atmosphere may be 30° or 40° below what he supposed it to be; and the explanation of the fact ought to be sought in the influence of a sun constantly above the horizon in the summer months compensating in a great degree for the obliquity of its rays, in the aërial currents above alluded to, and perhaps in a greater degree to the oceanic currents. The observations of Humboldt and Dr Hooker, and of others, show how very much the height of the snow-line, in different sides of the same range of mountains, is influenced by radiation from adjoining plains and conditions of aspect. That the reflection of the sun's rays from a snowy surface has a most powerful effect in a clear atmosphere, has been surmised by Professor James Forbes; and it will also be found, we doubt not, that there is a difference between the upper and lower limits of perpetual snow within the Polar Circle as great as on the sides of high mountain ranges. It is certain that phænogamous vegetation is not extinct in the most northern lands that have been attained.

In Dove's isothermal charts, constructed on Baron Humboldt's plan, an elliptical area of greatest cold is placed in Northern Siberia, reaching from Lat. 60. to 81., and including the whole valley of the Lena, with the western part of New Siberia, and the adjoining border of Wrangel's supposed Polynia. Round this (mesocheimal) lines of mid-winter temperatures are protracted in curves, which are far from being regular, but which have all a tendency to form ellipses. Taking these curves as expositions of facts so far as known, they indicate the mildest winters to be in the meridians of Bering's Straits and of the Spitzbergen seas, the most severe being in the parts of Asia and America farthest from these seas. The curves or ellipsoids of mid-summer (mesothæral) heat have their long axes almost at right angles to the winter ones, the summers of Bering's Straits and Spitzbergen being cool compared with those of the continental projections to the north. The district of greatest heat round which the very irregularly flexed mesothæral lines circulate embraces the Persian Gulf and Red Sea, with the intervening Arabian peninsula and the eastern coast of Nubia. The annual isothermals take of course an intermediate direction between the isothærals and isocheimals; and the mean of 32° F., or the freezing-point, passes from a point on the 60th parallel someway south of Bering's Straits, cuts off the southern quarter of Kamtschatka, part of the Sea of Ochotsk, curves regularly by Sagalien on the Amour, and, after touching the 49th parallel, ascends gradually by the south of Tobolsk to the White Sea, north of Archangel; and then, having first dipped suddenly to the

---

[1] This was ascertained by Tatarinow and Pschenitza in 1811, Hendenström in 1810, Lieutenant Anjou in 1823, and by Wrangel and his assistants during his various journeys performed between 1820 and 1823.

Gulf of Bothnia, rises rapidly beyond the North Cape to the 72d parallel; whence, taking a descending curve, it grazes the north end of Iceland, cuts the south point of Greenland, and reaches its second southern apsis near the 49th parallel, in the bottom of James's or Hudson's Bay; then, rising in its course through Rupert's Land and the basin of the Mackenzie to the 63d parallel, descends through Russian America to meet the point in Bering's Sea from whence we commenced tracing it.

Though the subjoined thermometric table partakes of the inaccuracies which result from causes alluded to above, it is an abstract of the most complete series of observations that we have been able to collect. By it we are led to infer that the winter cold increases with the latitude on the same meridian within the Arctic Circle, while there is a great uniformity of summer temperature between the parallels of 70° and 75°, from Lancaster Sound to Bering's Straits. Between the parallels of 76° and 81° the summer heat of Spitzbergen, Smith's Sound, and Wellington Sound is nearly alike, and a degree or two below that of Lancaster and Melville sounds. These observations may be neither sufficiently continuous nor correct to disprove the existence of an open Polar basin, yet as far as they go they tend that way.

It is an established fact, that as we descend into the interior of the earth through the shafts of deep mines, the temperature rises,—according to some at the rate of one degree of Fahrenheit's scale for every forty-five feet of descent; but the increment varies in different localities, and cannot be considered as having been as yet perfectly ascertained over any one extensive district. The superficial crust or soil is moreover influenced by the direct impact of the sun's rays in summer, and, in winters of high latitudes, by radiation into space, and long-continued contact of a cold atmosphere. In all cases, however, the thermal effects of seasons descend like tides through the soil, becoming gradually less and less distinct as the distance from the surface increases, and finally blending and vanishing at depths which vary with the latitude and also with local causes. In severe Polar climates the result is a permanently frozen substratum, whose southern limit is placed by Baër in coincidence with the isothermal line of 32° F., its thickness increasing of course with the decrease of mean temperature calculated for a series of years. At Yakutsk in Siberia, where the mean heat of the year is +14° F., the frozen earth is 382 feet in thickness; but at York Factory, a few miles from Hudson's Bay, where the mean temperature is +25½° F., the frozen substratum was cut through at the depth of 20½ feet: at that place the superficial summer thaw penetrated about three feet. At Fort Simpson on the Mackenzie, five degrees to the north of York Factory, but possessing nearly the same mean annual temperature, the soil was thawed at the close of summer to the depth of eleven feet, beneath which lay a stratum of only six feet of permanently frozen soil, the underlying loose sandy soil being unfrozen at the depth of seventeen feet from the surface of the ground. Throughout the northern shores of the American continent, and in the islands beyond it, the summer thaw penetrates from ten inches to a foot, or a little more; but no shafts have been sunk in America within the Arctic Circle to ascertain the thickness of the permanently frozen substratum.

Spitzbergen lies on the verge of the snow-line,—some low-lying tracts of meadow becoming bare in summer, and also the steep faces of hills; so that enough of grass and lichens are produced to nourish herds of rein-deer; but the higher grounds are covered with snow, and the valleys occupied by glaciers. In Smith's Sound (Lat. 78. 79.) some patches of ground became visible in the first weeks of July on which many flowering plants flourished. *Hesperis pygmæa* and *Vesicaria arctica* were found in fruit by Dr Kane as far north as 81°, accompanied by other phænogamous plants of various families, whose fruits require a considerable number of summer days for ripening. Even dwarf, shrubby *Vaccinia*, *Empetra*, and *Salices* attain the height of Smith's Sound. The east side of that strait, and a great part of Greenland in general. has its valleys and the gorges of its fiords occupied by glaciers; and it is probable that the interior of the northern parts at least are, like Spitzbergen, covered permanently with snow, the only bare spots in summer being steep acclivities lying well to the mid-day sun, or strips of meadow land on the coast. Farther to the westward, in latitude 77° north of Wellington Sound, Sir Edward Belcher observed the lower grounds to become partially denuded of snow early in June; and in the spring of 1851 Mr Goodsir saw patches of bare earth on the 10th of June, the snow at that period being in process of rapid waste. Sir Edward Parry notes a period of seventy days, from June to September, during which vegetation goes on in the low grounds of Melville Island, latitude 74½°. Snow showers are of occasional occurrence in those quarters in every summer month, but soon after the beginning of September the snow that falls is permanent for the winter.

In no part of America within the Arctic Circle where cereals have been sown has success attended the operation, though the cultivation of barley reaches the 70th parallel on the Scandinavian peninsula. On the Mackenzie, turnips and radishes alone of the culinary vegetables could be raised on the 67th parallel. At Shredoi Kolymsk, in 67½°, on the Kolyma, radishes and cabbages without heads were the poor rewards of the kitchen gardener's toil; and a degree farther north, at Nijnei Kolymsk, the climate is so severe that in a low marsh near the village, ice, mixed with vegetable earth, remains frozen the whole year. There the river freezes in September, and the winter is nine months long. Baron Wrangel mentions the occasional occurrence of warm winds, named *teploi weter*, which blow from the south-east by south in the middle of winter, and raise the temperature in the course of twenty-four hours from 47° below zero to 35° above it. Similar warm winds recur once or twice in the winter in the higher latitudes of America, sometimes in December, more frequently in January or February; so that sometimes one, sometimes another, of these months is the coldest in the year. The great effect of these temporary winds proves how much aërial currents may influence the mean temperature of a locality.

The *northern termination of the woods*, though in some degree dependent on soil, and still more on elevation and vicinity of the sea, yet furnishes an approximate measure of the climate of various meridians. In Northern Asia the *line of woods* undulates considerably, yet its general course rises from the verge of the Arctic Circle in Bering's Straits to 71° on the deltas of the Jana and Lena. On the Lulean Alps, Scotch firs (which there ascend above the spruces, and 200 feet above the limit at which barley ceases to ripen) terminate at an altitude of 1300 feet, and the lower edge of the snow-line varies there from 3100 to 4100 feet above the sea, according to aspect. Some *Ranunculi* and similar plants grow above the snow-line in the crevices of steep rocks, where the sun's rays have power; and a few lichens (*Gyrophoræ*) ascend 2000 feet higher. At the island of Mageröe, off the North Cape of Europe, the line of perpetual congelation is about 1100 feet above the sea-level, and trees grow at no great distance from the sea on the northern coasts of Lapland and Finmark. In Greenland there are no trees; but on the west side of Hudson's Bay the line of woods commences between the 60th and 61st parallels, and, inclining to the north as it runs westward, reaches the 68th parallel on the alluvial banks of the Mackenzie, though it does not come so far north on the higher grounds. On Noatak River, which falls into Eschscholtz Bay, the wood-line is coincident with the Arctic Circle; and that curve probably represents its course from Noatak eastward to the Mackenzie, except on the Colville, where the low fertile alluvium may cause it to bend to the north. In the severe Arctic climates, trees are frozen to the centre in winter, but under the influence of the spring sun, travelling above the horizon throughout the twenty-four hours, they are thawed long before there is any material diminution of the snow which covers the frozen soil in which their roots are fixed; yet the deciduous trees show neither leaves nor flowers until the snow has wholly or nearly disappeared.

Animals.

Our restricted space will not permit us to extend those very general remarks on the climate and vegetation of the Polar regions. Certain animals, such as the Canadian lynx, the American hare, and the Moose-deer, are limited in their range by the line of woods,—the latter wandering northwards of the woody country only on river banks whereon thickets of willows grow. The goat antelope (*Aploceros montanus*) and the small Pika or tailless hare, are confined to the Rocky Mountain ridge, which they follow to within the verge of the Arctic Circle; and the magnificent Argali or Big-horn also ranges to the northern termination of the same ridge, in the parallels of 68° or 69°. The Rein-deer has been found in the most northern lands to which navigators have attained; and the Musk-ox, though more partial in its distribution, also attains a high latitude; while the Polar hare and several kinds of Lemmings are residents on all the Arctic islands which produce any kind of vegetation. These herbivorous quadrupeds are accompanied by the Wolf, Wolverine, and Arctic Fox. The Brown Bear also roams over the Arctic wastes of the continents of Europe, Asia, and America; while the White Bear is the tyrant of the Polar seas, making the seals which abound therein its peculiar prey. Some small herds of rein-deer and musk-oxen having been seen on the islands of Melville Sound in the winter, have led some to deny the migrations of these animals; but only a few can find food in the Polar islands during winter, and it is unquestionable that the rein-deer retire in vast herds southwards on the close of summer to the borders of the woody country, where the males and females congregate in the rutting season. In the spring the females, travelling alone, seek the sea-coast to bring forth their young. At that season the *Cenomyces*, *Corniculariæ*, and *Cetrariæ* which clothe the more barren districts like a carpet, become soft and tender amid the melting snow, and furnish fitting food for the does and their young. The grasses and carices also, which grow freely in the alluvial meadows on the coast, are only then shedding their seeds, and still retain some sap in their culms, the sudden autumn frosts having arrested their fructiferous functions, which are not completed till the snow is disappearing on the approach of midsummer. The same may be said of the berry-bearing plants, the *Empetra*, *Vaccinia*, and *Rubi*, whose frozen fruits remain pendant over winter, and when uncovered by the melting snows, supply bears and geese with stores of food.

The Polar regions are the native country of many geese, ducks, and aquatic birds. The Canada goose is the only North American member of that genus which breeds below the Arctic Circle, and many bands even of them travel as far as 68°; while the Barnacle, Brent, Laughing-Goose, and Snow-Goose go to the extreme north to breed. Ptarmigan and Dovekies may be said to be constant residents in the highest latitudes; but the bulk of both these species go southwards for their winter food, though a few dovekies linger behind in the open pools of the Polar Sea. The Raven and Snowy Owl are the only birds of prey that find food within the Arctic Circle in the winter time.

Whales and seals must not be overlooked in any notice, however brief, of the animals of the Polar regions. Taken in conjunction with marine and fresh-water fish and the rein-deer, they are the productions which render the hyperborean lands and seas habitable for the Eskimos. Like the rein-deer, the Right Whales produce their young in the solitudes of the icy seas, but have their equatorial limits between the 30th and 45th parallels.[1] This range of the Right Whale may be called a zoological district, and it is not dissimilar in extent to the ranges of the Snow and Barnacle Geese, which leave their Polar native places to pass the winter on the elevated Mexican plateaux.

Eskimos.

The Eskimos are a people fitted peculiarly to dwell within the Arctic Circle. They occupy the whole of the sea-board of Arctic America, continent and islands, the entire coast of Greenland, and both sides of the peninsula of Labrador. In Greenland, Labrador, and Hudson's Bay only, have Europeans fixed themselves on the Eskimo lands; and though in one or two districts the American red races have, through the more early possession of fire-arms, been able to restrict the southern range of the Eskimos, they have nowhere dwelt among them in America, except on Bering's Sea, where there is a fusion of races. The Eskimo not only subsists in the high latitudes, but has much enjoyment in his routine of duties, which vary with the seasons, and he even prefers his frigid wastes to what we consider more favoured lands. He may be said to be wholly independent of vegetable food, his chief luxury of that kind being the *nerooks* or half-digested lichens which he finds in the paunch of the rein-deer. Occasionally, also, he eats, when the chase fails, a few bistort roots, a little scurvy-grass, or whortle or crow berries in the autumn; but these make no important part of his diet. The nation is, in fact, more strictly carnivorous than any other that we know of; and as a diet consisting exclusively of animal food requires to be very plentiful, the skill and energy of the Eskimo hunter are fully taxed. In summer, at the epochs of the rein-deer migrations, he lays the passing herds under contribution in various ways. He snares them, traps them in pounds and pit-falls, spears them while crossing lakes or rivers, or stalks them, and shoots them with arrows. The skins, especially those of the young, furnish warm clothing for himself and family, the women being skilful in converting the hide into shamoy, or in dressing the fur; the back sinew, split into fine fibres, makes excellent thread; and the antlers and bones are shaped into knives, spear-heads, and fishing-hooks, or are used in the framing of sledges. Twisted into lines, the sinews, or sometimes thongs of the skin, are employed in making nets. The flesh of the rein-deer, dried in the sun or stored in a natural ice-cellar, is reserved for winter food; geese and other birds yielding abundant provision during the season of the autumn deer-hunt. In September, after the deer have passed southwards, the Eskimo families assemble on certain promontories to hunt the whale, and, if successful, they spend a luxurious winter, the blubber and oil of the whale, as well as its flesh, being pleasing to their palates. The oil also supplies their lamps, so essential in the dark winter months. The lamps are made of pot-stone, and the same material is excavated to make cooking-kettles; but these heavy utensils are less valued since the more portable copper kettles of Europe have become known in Eskimo-land. Of the whale's intestines, sails for the women's boats (*oomiaks*) are made, the gut being neatly sewed together in stripes; and of the same material waterproof shirts are formed, to be worn by the men when seated in their small *kajacks*. The ribs and other bones of the whale are used in framing sledges or canoes when drift-wood cannot be had, and also for rafters to the turf roofs of houses. These houses, whether framed of wood or bone, are half sunk in the ground, and are thickly covered with earth, so as to exclude the cold atmosphere; and, with the same view, the passage by which they are entered is long, low, and subterranean. In these *iglöacks* the height of the winter is passed; but when the return of the sun brings length of day, though as yet the air continues very cold, the winter houses are evacuated, and the families travel seaward on the ice to hunt for seals. By a skilful application of his knowledge of the habits of that wary animal, the expert Eskimo hunter brings a daily supply to his family. The seal-flesh is the most favourite food of the people, and its skins are dressed to make durable waterproof coverings for the kajacks and oomiaks, or cut into thongs for lines, which being slit circularly from the skin, are made of considerable length without knots. The skins of the lesser seals also are stripped off in the form of a bag, and the various apertures being very effectually and neatly plugged, are blown up to form an excellent buoy, used in hunting whales or large seals and morses. The Eskimo women are, moreover, very skilful in manufacturing waterproof boots of the seal-skin, or jackets for summer wear. During the spring seal-hunt the family is encamped on the ice in huts most elegantly built of blocks cut from the compact snow, and which endure until the ice begins to break up. In autumn, when the snow is neither deep enough nor sufficiently compact to serve for a building material, the Eskimo knows how to substitute slabs of ice—the cold acting the part of a cement. The only domestic animal the American Eskimo possesses is the dog, which he employs both for the draught and the chase. Formerly it is probable that the Eskimos crossed Bering's Straits, and occupied the coast as far as the Kolyma, or even farther towards Europe. The Namollos of the Gulf of Anadyr are, according to Sauer, a tribe of Eskimos; and traces of Eskimo dwellings have been discovered along the northern shores of Asia as far as the 160th meridian. The more powerful Rein-deer Tchuktche, supposed to be of Tatar origin, are considered as the invaders of the Namollo territory. Throughout the vast linear range of the Eskimos the variations in the language are merely dialectic. The Samöeids have much physical resemblance to the Eskimos, which, as far as such evidence goes, points to a common Mongol origin; but neither the Tchuktche, the Yeniseians, Yukahivi, Samöeids, nor Laps seem to have the nautical skill of the Eskimos, to be able to hunt the whale on the high seas, or to obtain a living on an ice-bound ocean. The domestic habits of the nations just named rather resemble those of the American red races in high latitudes, especially their modes of cradling their infants, and are to be attributed to the precautions that experience has taught them to use against the severity of the climate. The Eskimo kajack is peculiar to the nation. Olaus Magnus mentions that in the year 1505 he saw two suspended in the cathedral church of St Halvard at Aslo, which were reported to have been brought from Greenland by King Haco when he visited that country with a hostile fleet.

[1] Maury's Chart, *Phys. Geogr. of the Sea.*

Minerals.

In Arctic America, part of Baffin's Bay, the east end of Barrow's Strait, and the continental coast and adjoining islands of Melville Peninsula, the S. end of Boothia, and from thence to the Coppermine, the rocks are mostly granitic, ancient trap, or metamorphic. Farther to the W., and in the islands more to the N., there are considerable tracts of Silurian limestone, and also carboniferous limestones and sandstones; and as far N. as 76½°, at Prince Patrick's Island, liassic fossils have been found. The coal beds of Melville Island belong to the true coal formation, and the beds are supposed to be low in the series; but there is a tertiary coal at Disco in Greenland, on Cape Bathurst on the 127th meridian, and on the Garry Islands at the mouth of the Mackenzie, very similar to the coal higher up the Mackenzie, at the influx of Bear Lake River, and which, from the fossil plants it contains, was judged to be of the miocene age. Moreover, a pleistocene drift seems to be scattered over the horizontal Silurian and Devonian beds, to the height of 500 feet above the present sea-level.

Fossils.

But perhaps the most interesting of all the deposits of past times are vast multitudes of animal remains, in forms very similar to, and in some cases not to be distinguished from, those which are still inhabitants of the face of the earth. The bones brought from the extraordinary ice-cliffs of Eschscholtz Bay, on the verge of the Arctic Circle, were those of the *Elephas primigenius;* the *Equus fossilis,* in no respect different from the bones of the existing horse of the same medium size; the *Cervus tarandus;* the *Ovibos moschatus,* both of them equally like the bones of the existing species; *Ovibos maximus,* of larger size than the musk-ox, but of the same genus; *Bison priscus* (?) vel *americanus* (?); *Bison crassicornis; Cervus alces.* The elephant tusks have been for many years an object of traffic with the natives, who find them in abundance on the Kuskokwim River, on the 60th parallel, and several of the inlets communicating with Bering's Sea and Strait; and an entire skeleton of an elephant was found far inland in the elevated country near the sources of the Yukon, but none has as yet been discovered to the E. of the Rocky Mountain chain. The two fore extremities of a Mastodon, found far to the S., not a great way from the W. side of Lake Winipeg, are the only fossil bones that have been met with in Rupert's Land. The Eschscholtz Bay deposits, full of interest as they are, sink into insignificance when compared with the vast masses of fossil bones on the islands N. of the Asiatic Sviatoi Noss, lying between the 73d and 76th degrees of north latitude. Some of these islands, which are of considerable extent, seem to consist mostly of organic remains, which occupy more space than the solidly frozen matrix in which they lie, and from which, as it thaws annually under the direct influence of the summer sun, the bones drop or are quarried by the natives. Ever since that coast was discovered by the Yakutsk hunters the removal of bones has been going on; and in the year 1821, 20,000 lb. of fossil ivory was procured from the island of New Siberia alone, some of the tusks weighing 480 lb. The skull, flesh, and skin of the *Rhinoceros tichorinus* have been obtained from thence, and the discovery of the entire carcase of a mammoth at the mouth of the Lena in 1779 has been repeatedly commented upon in popular works. The charnel-house smell, and the remains of hair and horn in the Eschscholtz ice-cliffs, tell a similar story of the slow progress of decay since these vast and curious assemblages of animals were entombed in these two localities, lying 50° of longitude apart. The elephant and rhinoceros do not exist on the American continent at the present day, nor in Siberia. The horse was introduced into the former by the Spaniards; and of the other species enumerated above, the musk-ox at the same geological epoch existed in Europe, Professor Owen having identified a skull found in England with the American species. The conditions of sea and land when such accumulations were possible are subjects of conjecture and speculation on which we cannot enter here.

ANTARCTIC POLAR REGIONS.

Our knowledge of the North Polar seas and lands is the result of the search for a strait leading to the Pacific; but the exploration of the Antarctic regions is mainly due to quests after a *Terra Australis incognita.* The belief in the existence of an Antarctic continent can be traced back to the year 1576, when Juan Fernandez sailed from the coast of Chile on a W.S.W. course, and was reported to have arrived, after a month's voyage, at a *tierra ferme*, a pleasant, fertile land inhabited by highly civilized white people, dressed in woven cloth. If this story be not altogether apocryphal, it may be explained in part by supposing that Fernandez reached the coasts of New Zealand. At this time reports were in circulation respecting the Saloman Islands, discovered by Alvaro Mendana de Neyra in 1567, but which that seaman was unable to find on a second voyage made in 1595. The Saloman Islands were supposed so to abound in silver that in one place an entire mountain was composed of the precious metal. Mendana, however, did not realize the hopes that had prompted his enterprise: he and many of his companions died at Santa Cruz or Egmont Island, and the chief pilot, Pedro Fernandez de Quiros, conducted the shattered remnant of the squadron to Manilla. This same Quiros was the first who sailed professedly to seek the *Tierra Austral.* His voyage, performed in 1605–6, had for result the discovery of Pitcairn's Island, the New Hebrides, and various other islands; and the passage of two vessels of the squadron, led by Luis Vaes de Torres, through the strait between Australia and New Guinea; but neither Quiros nor his second in command, Torres, went far to the south. Seven years previous to Quiros' voyage, or in 1599, Dirk Cherrits, in endeavouring to enter Magelhaen's Strait, in company with some ships belonging to Rotterdam, was separated from them in tempestuous weather, and driven southwards to latitude 64°, when he saw a high snowy land, since known by the name of South Shetland, and ascertained to extend southwards across the Antarctic Circle. Other voyages to the S. followed; but Captain Cook is the first navigator who is known to have actually entered within the circle just named. His voyage in 1773–4 was undertaken, as he states, to ascertain whether the unexplored part of the Southern Hemisphere be only an immense mass of water, or contains another continent, as speculative geography seemed to suggest. Of the discoveries that our great navigator made exterior to the Antarctic Circle this is not the place to speak; and it is merely necessary to say that he saw no land to the S. of Southern Thule or Sandwich Land, on the parallel of 60. S.; and that he entered within the Antarctic Circle only thrice, and for short distances,—namely, near the meridian of 40. E., between 100. and 110. W., and between 135. and 148. W.; the most southerly point attained to by him being 71. 10. S., on the 107th meridian, and on the 30th of January 1774. The Russian Bellinghausen discovered Petra Island in January 1821; Weddell in 1823 proceeded 3 degrees farther S. than Cook; Biscoe in 1831–3 discovered Enderby and Kemp islands, lying between the meridians of 45. and 60. E. Balleny in 1839 discovered Sabrina Land and the small islands which bear his name; and Dumont D'Urville saw Adelie Land in 1840. These lands are mostly exterior to the Antarctic Circle; the S. end of South Shetland, Balleny, and Petra islands being the only lands that actually cross it. South Victoria, containing Mount Terror, 10,880 feet high, and the active volcano Mount Erebus, 12,400 feet high, is the discovery of Rear-Admiral Sir James Clark Ross. The farthest point of south latitude reached by this persevering and enterprising officer was 78. 4. S.; and the Parry Mountains, the most southern known land, were seen extending about as far S. This southern land was traced from N. to S. for about 460 miles, and found everywhere barricaded by a high ledge of ice, on which a heavy surf was beating; so that landing was impossible, except on some small islands, which consisted of igneous rocks. The surface was everywhere thickly covered with snow, and there was not the smallest vestige of vegetation; but on the islands there were inconceivable myriads of penguins, whose deposits had formed a deep bed of guano. Cockburn Island, one of the South Shetland group, and not above a mile in diameter, but rising 2760 feet above the sea, lying in Lat. 64. 12. S., Long. 59. 49. W., is the most southern land on which vegetation has been detected. Its flora contains nineteen species, all belonging to the orders of mosses, algæ, and lichens. The cliffs were streaked with the yellow *Lecanora miniata*; the *Ulva crispa* grew on the beach in decaying organized substances; and the minute mosses in the fissures of the rocks. One of the algæ inhabited a pool of fresh water hardly two spans across, and sheltered by a projecting rock; the earth at the bottom, perhaps half an inch below, was hard frozen, and the water itself just thawing in the unusual warmth of the day which had raised the thermometer to 40° Fahrenheit. *Collema crispa* grew on the borders of the pool, and with it a green microscopic *Conferva lecanora.* The sea-weeds *Iridæa micans* and *Adenocystis Lessoni*, gathered on the shores of the island, were all floating. Vegetation could not be traced above a ledge of rocks which girt the island at the height of 1400 feet. The lichens ascended the highest. This land, therefore, lying 3½° from the Antarctic Circle, on the outside, has a climate approaching closer to the absolute and perpetual snow-line than Arctic land approaching 17° nearer to the Pole. No terrestrial quadruped inhabits the lands within the Antarctic Circle, the marine cetaceans and seals being the only mammals that enter its area or approach it within many degrees of latitude. Organized specially to inhabit the chilly Antarctic waste of waters, the almost scaly Penguins resemble the Walrus and Seals in being able to travel long and far beneath the surface of the ocean, in seeking their food in its depths, and in scarcely quitting it except for the purposes of incubation. Indeed one species, the *Solitary Penguin*, carries its egg with it in a fold of skin when it roams far in search of food. The existence of such a creature, and of the *Dodo*, *Moa*, &c., furnishes an argument of certain species having been created solely for limited districts.

A glance at the north and south circumpolar maps will show the great contrast between the Arctic and Antarctic areas,—the one mostly of land, the other of sea. Aërial and marine currents operate in both in modifying the climate, and meet with less interference in the south; yet the summer temperature of the Antarctic Circle is the inferior one. Sir James Ross ascertained the mean temperature within the Antarctic Circle in 1841, for January, February, and March, to be 27°·3,—that of February, passed in the highest latitude, being only 24°·3 Fahr.; while the temperature of the surface sea-water for the first two months, passed between Lat. 66½. and 78., scarcely varied from 29°·2 Fahr. (J. R—N.)

POLARIZATION OF LIGHT. See Optics, part vii.

POLE, Reginald, cardinal, and Archbishop of Canterbury, a younger son of Sir Richard Pole, Lord Montague, was born at Stoverton Castle in Staffordshire, in the year 1500. At seven years of age he was sent to a Carthusian monastery at Shene, near Richmond in Surrey; and thence, when he was about twelve years old, removed to Magdalen College in Oxford, where, by the instruction of the celebrated Linacre and Latimer, he made considerable progress in learning. In 1515 he took the degree of Bachelor of Arts, and was admitted to deacon's orders some time afterwards; in 1517 he was made prebendary of Salisbury; and in 1519 dean of Wimborne and of Exeter. We are not surprised at this young nobleman's early preferments, when we consider him as the kinsman of Henry VIII., and that he was bred to the church by the king's special command.

Being now about the age of nineteen, he was sent, according to the fashion of the times, to finish his studies at Padua in Italy, where he resided some time in great splendour, having a handsome pension from the king. In 1525 he returned to England, where he was most graciously received at court, and universally admired for his talents and address; but preferring study and sequestration to the pleasures of a court, he retired to the Carthusian convent at Shene, where he had continued about two years, when the king began to divulge his scruples of conscience concerning his marriage with Catharine of Spain. Pole foresaw that this affair would necessarily involve him in difficulties; he therefore determined to quit the kingdom, and accordingly obtained leave to visit Paris. Having thus avoided the storm for the present, he returned once more to his convent at Shene; but his tranquillity was again interrupted by the king's resolution to shake off the Pope's supremacy, of which Pole's approbation was thought indispensably necessary. How he managed in this affair is not very clear. However, he obtained leave to revisit Italy, and his pension was continued for some time.

The king, having now divorced Queen Catharine, married Anne Boleyn; and being resolved to throw off the papal yoke, ordered Dr Richard Sampson to write a book in justification of his proceedings, which he sent to Pole for his opinion. To this Pole, secure in the Pope's protection, wrote a vehement answer, entitled *Pro Unitate Ecclesiastica*, and sent it to the king, who was so much offended with the contents that he withdrew his pension, stripped him of all his preferments, and procured an act of attainder to be passed against him. In the meantime Pole was created a cardinal, and sent in quality of nuncio to different parts of Europe. Henry made several attempts to have him secured and brought to England, but all of them proved abortive. At length the Pope fixed him as legate at Viterbo, where he continued till the year 1543, when he was appointed legate at the council of Trent, and was afterwards employed by the Pope as his chief counsellor.

Pope Paul III. having died in 1540, Pole was twice elected his successor, and, we are told, twice refused the papal dignity,—the first time, because the election was made in too great haste; and the second, because it was done in the night. Cardinal Maria de Monte obtained the triple crown; and Pole, having kissed his slipper, retired to the convent of Magazune, near Verona, where he continued till the death of Edward VI. in the year 1553. On the accession of Queen Mary, Pole was sent as legate to England, where he was received by her Majesty with great veneration, and conducted to the archbishop's palace at Lambeth, Thomas Cranmer being at that time prisoner in the Tower. He immediately appeared in the House of Lords, where he made a long speech; and this being reported to the Commons by their speaker, both these Houses concurred in an humble supplication to be reconciled to the see of Rome. They presented it on their knees to her Majesty, who interceded with the cardinal, and he graciously condescended to give them absolution. This business being ended, the legate made his public entry into London, and immediately set about the extirpation of heresy. The day after the execution of Cranmer, which he is falsely said to have advised, he was consecrated archbishop of Canterbury. In the same year, 1556, he was elected chancellor of the university of Oxford, and soon afterwards of Cambridge, both which he visited by his commissioners. He died of a double quartan ague in the year 1558, about sixteen hours after the death of the queen, and was buried in the cathedral of Canterbury.

As to his character, the Catholic writers ascribe to him every virtue under heaven; and even Bishop Burnet is lavish in his praise, attributing the cruelties of Mary's reign to the advice of Gardiner. In this Mr Hume agrees with the bishop, and represents Pole as the advocate of toleration. By every impartial account, he seems to have been a man of mild manners and of real worth, though undoubtedly a zealous member of the Church of Rome. His Life was written by T. Phillips, 2 vols., 1767; a Review of the Life, by Dr Gloster Ridley, and animadversions upon it, by Dr T. Neve, 1766.

POLE (πόλος, *a hinge*), was applied formerly to the extremities of the axis of the celestial sphere in the ancient astronomy; and hence it has come to signify the extremities of the axis on which the earth turns. From this primary signification all the various uses of the word have been derived. It came to be applied to those points which would become poles of rotation if any great circle of the sphere became the equator. In *Physics* it signifies, in general, any tendency towards polarity; and in *Geometry* it is equally loose.

POLE. See Perch.

POLEMARCHUS. See Archon.

POLETÆ (πωληταί, *those who let*) were ten officers at Athens, who, like the Roman censors, let out the taxes and other revenues to the highest bidders, and sold confiscated property.

POLEVOY, Nikolai Alexievich, a voluminous Russian author, was born at Irkutsk in Siberia in 1796. His first notoriety was gained in the character of an infant prodigy. Learning seemed to come to him by instinct. At the age of six, he picked up a knowledge of reading from an elder sister. Although sent to work soon afterwards in his father's brandy distillery and pottery, he busied his little head with nothing else but literature. The composition of newspapers and dramas became the amusement of his leisure hours. No book fell in his way which his mind did not eagerly devour, and his memory did not easily retain. Thus by the time that he had reached the age of fifteen he was a practised author, had read a thousand volumes, and could repeat long scraps of his readings off by heart. Equally remarkable for its enthusiasm was the manhood of Polevoy. Adopting the literary profession at Moscow in 1825, he entered upon a career of almost unexampled activity. The *Moscow Telegraph* was conducted, and its best material supplied, by his own hand. Plays and romances followed in rapid succession from his pen. An elaborate *History of Russia* at the same time advanced till it had reached the twelfth volume. Still more intense did his ardour become when he had removed to St Petersburg. Not content with editing several journals, his prolific mind threw off tragedies, comedies, farces, tales, essays, and translations from Shakspeare. He soon, in fact, outran both his readers and critics, and produced books which were doomed to neglect. The result was, that his fame began to decline, and his health at the same time began to give way. He died in 1846, with a body which had been worn out by incessant exertion, and with a reputation which had not fulfilled its early promise. Among the most important works of Polevoy are *Sketches of Russian Literature*, in 2 vols. 8vo, St Petersburg, 1839; *Dramatic Works and Translations*, in 4 vols., St Petersburg, 1842–43; and *Life of Peter the Great*, in 4 vols., 1843. (See Knight's *English Cyclopædia of Biography*.)

POLI, Giuseppe Xaverio, the "Neapolitan Pliny," was born at Molfetta, in the kingdom of Naples, in 1746. He passed through a course of training which was peculiarly fitted to develop his talent for natural history. At the university of Padua, Morgagni the anatomist was his professor, and Scarpa the anatomist was his friend and fellow-student. In 1776 his promotion to the chair of geography in the military academy at Naples encouraged his scientific zeal. Still more useful was the appointment which he shortly afterwards received to visit the educational establishments of France, Germany, and England. He seized the opportunity of making a collection of shells in all the different districts which he visited, and of gathering hints on natural history from the various eminent foreigners whom he met. Accordingly, after Poli had returned home and had been installed in the chair of experimental philosophy at Naples, the result of this long course of education began to appear. In 1791–95 the first two volumes of his great work *Testacea Utriusque Siciliæ*, illustrated with beautiful steel engravings, were published. He was engaged in preparing the remaining volume when he died in 1825. It appeared not long afterwards.

POLICASTRO, a town of Naples in the province of Principato Citra, on the shore of the gulf of the same name, 22 miles S. of Diano. It has a Gothic cathedral, and was once a place of much importance; but it was taken and sacked by the Turks in the sixteenth century, and has never since recovered its former prosperity. There is a good harbour; and the inhabitants are actively engaged in fishery. Pop. 7000.

POLICE.

Few political questions have been discussed, from time to time, with greater conflict of opinion, or with more of controversial keenness, than have those which relate to the functions, the limitations, and the control of Police. The very definitions of the word which we meet with in our ordinary dictionaries and legal text-books, indicate, by their vagueness and elasticity, how various are the points of view from which police arrangements may be regarded, and how numerous are the links which connect a subject, familiar even to triteness under some of its aspects, with not a few of the most complex problems of the thorny science of government.

urrent efinitions.

Johnson tells us that by "police" is meant "the regulation and government of the city and country, so far as regards the inhabitants" (adding that the word is a French one); which is little more than an abridgment of the passage in which Blackstone says,—"By the public police and economy, I mean the due regulation and domestic order of the kingdom, whereby the individuals of a State, like members of a well-governed family, are bound to conform their general behaviour to the rules of propriety, good neighbourhood, and good manners; and to be decent, industrious, and inoffensive in their respective stations."[1] This, certainly, is a comprehensive definition; elastic enough to include alike the police systems of countries where individual liberty is jealously guarded, and those which exist where statecraft has victoriously established its most repressive agencies.

ntham's finition.

Bentham's definition will contrast favourably with these, as respects both precision and limitation. Police, he says, "is, in general, a system of precaution, either for the prevention of crimes or of calamities. . . . Its business may be distributed into eight distinct branches,—1. Police for the prevention of offences; 2. Police for the prevention of calamities; 3. Police for the prevention of endemic diseases; 4. Police of charity; 5. Police of interior communications; 6. Police of public amusements; 7. Police for recent intelligence and information; 8. Police for registration."[2] There is here, we think, a definition clear and practical, and little open to exception, save in the phrase "police for recent intelligence," which is vague enough to cover a system of espionage, always more fruitful of evil than of good; and although by no means unattempted in this country, invariably condemned as soon as detected.

Conflict of local and central administration.

But in Britain the chief arena of conflicting opinion on this subject lies rather in the control of police than in its functions. The claims of local self-government come here into contact with those of central administration, and the questions recur, "Is it wise to sacrifice something of executive efficiency for the better maintenance of the old constitutional safeguards?" And if it be, "How can the sacrifice be made as small as possible?" Nor is it uninteresting to remember that in all these current discussions about "dangers of centralization," and the like, we have but mediæval questions under a new phase. The citizens and burgesses who, now-a-days at very short intervals, call meetings, sign petitions, and appoint deputations, to protest against the subtle designs of Boards of Health and of Secretaries of State, are but imitating, in modern fashion, those early burghers who made the walled town a sturdy rival to the feudal castle, and who were in the habit of keeping their weapons at least as sharp as their words.

To attempt, even in briefest form, a historical review of the police institutions of all the prominent countries of Europe would greatly exceed the needful limits of this article. For such an account there are ample and little-used materials, and it might be made a useful contribution to our political literature. But here it must suffice to look mainly at the experience, in this matter, of France and of Britain. The one will present us with the most elaborate police machinery that human ingenuity has yet built up, by dint of long-continued application, and under little check from without; the other, until a very recent date, with a series of mere hand-to-mouth expedients, each of them postponed to the last moment, adapted to meet some pressing emergency, and watched in its working by a jealous public opinion. On the one hand, we shall have to keep in view the plain truth, that a nation may pay too dearly even for the repression of crime, and may after all far overshoot the mark; on the other, grave facts will be frequently suggesting the readiness with which petty and tortuous interests assume the mask of a care for liberty, and the necessity that instruments of police,—those especially which strike at the roots of crime, and not merely at its spray,—should have free scope and be held in a firm grasp, if they are to be used effectively.

I. The Police of France.

The rise of police in France.

In France, as elsewhere, the organization of police for the repression of crime has its beginnings amidst the strife of conflicting powers. Manorial lordships and clerical privileges of sanctuary are found to present tough obstacles to the due punishment of evil-doers, and those to whom the task is committed have to cast about for some effectual means of surmounting the difficulty. If the same body of men, whose claim to accord the privilege of sanctuary has become a covert to the vilest criminals, is found inflicting atrocious punishments on its own dependants for slight offences, an opening is made for innovation, of which a resolute hand can hardly fail to make good use. When Blanche, regent of France and mother of St Louis, at the head of some servants, hastily gathered at the news of the sufferings which the Chapter of Notre Dame was inflicting on men, women, and children, for default in a village tax, struck with her staff at the door of the Capitular prison,[1] she did something more than bring relief to its suffocating tenants. That blow had many echoes.

But we must pass rapidly over the initiative stage of the police of Paris. It will suffice to say that, until the end of the fifteenth century, the maintenance of the peace of the city, the pursuit and custody of criminals, and the suppression of vagrancy, were the functions of the provost of Paris. Towards 1450 much of the real power of that officer, in the police department, had passed into the hands of his lieutenants (*lieutenant civil du Châtelet; lieutenant criminel du Châtelet*), although the ultimate control lay still with him. Paris was divided into sixteen districts, each presided over by a commissary of police, with a certain number of sergeants (*sergents*) under him.

State of France under Charles VII.

The state of France at this period might well seem almost desperate. The long struggle with the English invaders was indeed almost at an end; but the departing foes left behind them devastated provinces and half-deserted towns. In many parts of the country, barbarism seemed to have resumed its reign. The bands called flayers (*écorcheurs*) were still striking a terror into the minds of the scanty population, the traces of which remained for centuries afterwards in oral tradition,[2] and may be seen still in the popular literature of the time. In Paris itself, wolves ranged the streets by night. Deserted, but not yet dismantled houses, stood in groups, closely shut up, but without claimants.[3]

Establishment of a royal control over the police of the kingdom.

To re-organize the police at such a time must have been a formidable task. Charles VII. took one resolute step, by vesting in the provost of Paris a general jurisdiction over the vagrants and malefactors of the kingdom. There was a great outcry; but some degree of order ensued, and the highways became passable. "The traders in various parts," says a chronicler, "began to resume their journeys; the peasants set to work to rebuild their cottages, to clear their fields, to trim their vines, and to weed their gardens. Towns and districts were restored and re-peopled. After having been so long in tribulation and sorrow, it seemed that God had at length extended to them his mercy and pardon."[4] This first step was followed up by the royal appointment of tax-assessors, who, in 1448, in addition to their ordinary functions, were directed to choose at least one man for each parish (*propice pour estre archer*), to be equipped as a bowman. The purpose was to get the nucleus of a militia; but the *Franc-archer* seems to have been occasionally policeman as well as militiaman. He was always a favourite subject of the jokers and the satirists of the day.

Police measures of Francis I.

About 1520 Francis I. created a special officer, called Provost-Marshal (*Prévôt des Maréchaux*), for the city and district of Paris, and gave him power both to apprehend and to punish vagrants and disorderly persons, without appeal. Thirty constables were placed under his orders. Francis I. also doubled the number of the commissaries of police, and that of their sergeants. The night-watch and town militia were at this period, as they had been for a long time before, distinct bodies, in which the towns-people were obliged to serve by rotation; but numerous exemptions had reduced both of them to inefficiency. Francis I. annulled most of the exemptions. Henry II. imposed a watch-rate on the traders and artizans, releasing them from their compulsory service, and replacing them by paid watchmen. He also established a municipal guard, composed of three companies,—bowmen, constables, and *arquebusiers*, or men with fire-arms.[5] These also were paid from municipal funds.

Retrospect at the main obstacles to good police

Drunkenness, ill-regulated lodging-houses, and the opportunities offered to thieves by shows and crowds in the public streets, are matters which we find pressing on the attention of the police functionaries of Paris in the fourteenth and fifteenth centuries, much as they do on those of our own towns in the nineteenth. As early as 1372, regulations occur for the regular closing of taverns, the responsibility of lodging-house keepers, and the restriction of street minstrels.[6] But here, as elsewhere, the regulations look more formidable on the record than the offenders in many cases found them to be in practice. Sturdy beggars and disbanded soldiers flocked to the capital in crowds, and the municipal force found itself ill able to make head against them. Even as late as 1560 it counted but 500 men of all ranks.[7]

Sale of royal pardons.

The repression of crime was also especially impeded by a monstrous abuse which had grown up at periods of financial embarrassment,—that, namely, of selling royal pardons for money. So far was this abuse carried, that we find instances of the release of criminals, at various stages of the procedure against them, by mere verbal order of the king, carried to the provost or his lieutenant by a chamberlain, a secretary, or a court usher. On strong remonstrance from the Parliaments, edicts appeared laying the blame on the importunities of courtiers, and forbidding the future release of persons in custody, save on the production of letters-patent passed in council, and sealed with the royal seal. But the evil was rather checked than cured.

Police of markets and of public health.

The police of markets and of public health is an interesting branch of this topic, the history of which in France is copious and remarkable. In our own country a considerable change has taken place of late years in public opinion on such matters. Measures of precaution which, not very long ago, were by turns ridiculed as puerile, or denounced as tyrannical, have commended themselves to legislative attention as both wise and essential. It has come to be increasingly apparent that the free use of weights and measures forms no part of the true doctrine of free trade, and that the liberty of wholesale poisoning is a very undesirable development of the liberty of the subject. A view of French practice in this department can hardly fail to be instructive, both when erroneous and when wisely directed. And it should be noticed, that the regulations made immediately for Paris were substantially those which governed the other cities and towns of the kingdom. In some particulars, very similar regulations will be found in the English statute-book, but with less of system and coherence.

[7] Frégier, i. 275.

As early as 1350 we find a royal ordinance of police which provides public weighing-offices, regulates the localities and the hours of open markets, and establishes an inspection of millers, bakers, and butchers. The last named proved to be an especially troublesome race. They took an active part in the disturbances occasioned by the quarrels of the dukes of Burgundy and Orleans and made themselves formidable partisans of the Burgundian faction, a service which was rewarded by special privileges accorded to the fraternity. Hence arose a sort of monopoly in course of time, and much employment for the police.

Police arrangements for cleaning, paving, and draining, 1399–1557.

The trade corporations.

The cleansing of the city was another troublesome department of duty. During the fourteenth and fifteenth centuries there were repeated enactments directing its discharge by the inhabitants, the owner or chief tenant of each house being bound to keep his own share of the street or highway free of encumbrance and dirt. But these were so little operative, that at length (in 1506) a cleansing rate was established. In order to make the novelty work as smoothly as possible, a committee of rate-payers was organized to co-operate with the commissaries of police.[1] It seems strange to read that, when contagious diseases were prevalent, this rate was tacitly suspended, and the cleansing left to the goodwill of each inhabitant. The reason assigned is, the probability that such an impost, added to existing privations, would excite disturbances.[2] Other regulations, however, of a sanitary kind, as, for example, the removal of noxious trades, were at such times enforced with more than usual strictness.[3] The earliest police enactment respecting sewers—such as they were,—and their appurtenances, is of the time of Charles VI.; but there are long anterior municipal regulations as to the provision of *latrines* to every house, on pain of confiscation of rents. Under Francis I., the houses themselves were forfeited if the law continued to be neglected.[4] The paving of streets, and the survey of houses in course of construction, are also the subject of many enactments (*e.g.*, 5th April 1399,[5] 28th July 1500, 16th Feb. 1533, 10th May 1538, March 1557-6[6]). Here the chief difficulties of the police seem to have arisen from the stringent rules of those wardenships and corporations of arts and trades (*jurandes et communautés des arts et métiers*), the procedures and influence of which, especially but not exclusively in France, form so striking a feature in the later portions of mediæval history, and in the earlier epochs of the history of modern Europe.[7] This conflict of authorities resulted in the increase of the powers of the provost and his officers.

Elective police magistrates appointed.

In 1577 a new development was given to the administration of police in Paris, by the power accorded to the inhabitants of each of the seventeen districts (the number had then recently been so augmented) to elect two police magistrates, empowered to hear and determine petty charges, involving only a small fine. The appeal from this summary jurisdiction lay to the weekly general meeting of police functionaries, presided over by the provost or one of his lieutenants. In addition to their judicial duties, these new magistrates acted, jointly with the commissaries of police, in the inspection of markets, workshops, and lodging-houses.[8] A further step towards the suppression of the baronial and manorial jurisdictions was taken in 1639, by the transfer of their powers in matters of police to the Châtelet.

Workhouses provided for able-bodied vagrants, and hospitals for the infirm, 1612–1618.

It was also in the reign of Louis XIII. that new measures were originated with a view to the suppression of mendicity. Workhouses in the faubourgs St Victor, St Marcel, and St Germain were provided for the reception of all vagrants. The first was assigned to able-bodied men, who were employed in grinding wheat, in pounding cements, in brewing, and other hard labour; the second to women and children, whose task was knitting, button-making, and other feminine occupations; the third was made an hospital for the infirm.[9] Within a week, a very large portion of the Paris mendicants were safely housed: sturdy beggars entirely disappeared from the streets; and for some years the plan was vigorously carried out; but eventually it proved to be a failure.

In the *Histoire Générale des Larrons* we have an authentic and singularly graphic account of the criminal and vagrant classes of the French, and especially of the Paris population, as they were under Louis XIII. They were organized much on the plan of the incorporated trades; had their system of apprenticeship, and of "freedom" on proof of competency; and their common fund, fed by a *pro rata* contribution from the proceeds of robberies. There are but few of the stratagems which excite attention for their ingenuity in the criminal reports of the nineteenth century, that were not practised with frequent success in the sixteenth and seventeenth centuries.

Police system established by Louis XIV.

Those extensive changes in the administration of police which the power and energy of Louis XIV. enabled him to introduce, with so much temporary profit to the predominance of the royal authority, tended undoubtedly to check ordinary crime, and to strengthen the hands of the judicial magistrates. But this increased vigour of the laws was obtained, as we shall see presently, at the cost of frightful abuses. The manorial and other exceptional jurisdictions were now wholly absorbed in the functions of the Châtelet. To meet the increase of its business, the single bench was divided into two, each with its separate provost and staff, but both collectively forming one body. A lieutenant-general of police was created, whose functions absorbed those of both the existing lieutenants, by whom the police duties of the provost had long been discharged. The double bench of the Châtelet lasted only for ten years, the inconveniences of the division having been found to exceed its advantages. But the office of lieutenant-general of police lasted from the 26th March 1667, when its functions were first conferred on M. de la Reynie, until the memorable 14th July 1789, when its last holder, M. Thiroux de

Frégier's book, we may add, is one of great labour and of great value; but it is impossible to praise its arrangement. The periods which form its leading divisions are arbitrary and unmeaning; what, at first glance, looks like an approach to chronological order proves on examination to be chaotic, and the baffled reader seeks in vain for an index. The neglect of clearness of dates becomes in many parts of the book quite ludicrous. In other respects, M. Frégier's work is praiseworthy and we are much indebted to it. Its continuation (on a better plan) from 1789 to the second empire would be a public service.

Crosne, hastened to place his post at the disposal of the conquerors of the Bastille as soon as they had established themselves in the Hôtel de Ville.

Character of De La Reynie, first lieutenant-general of police.

De La Reynie filled the office of lieutenant-general for thirty years, a period twice as long as that of the most tenacious of his successors. If we bear in mind what those thirty years were, the fact of itself almost paints the man's portrait. Able, supple, stern, and unscrupulous, we feel little surprise at meeting with him in that instructive chapter of French history which narrates the revocation of the edict of Nantes. In that fatal business he was a commissioner, and one of the most rigorous. Apart from that, the ordinary regulations of criminal procedure, in the preparation as well as the execution of which he had doubtless his share, are animated from the first page to the last by the principle that vigorous repression is everything,—the possible risk of condemning the innocent nothing. Scarcely was the accusation lodged, when the accused person began to be treated as guilty.[1] Of the many remarkable trials in which De La Reynie presided or held a prominent place, that perhaps of a female poisoner named La Voisin, is best remembered, from its having elicited a smart reply from the Duchess of Bouillon. The prisoner in this case (who was burnt in the Place de Grève in February 1680) had accused certain persons of high rank, of whom the duchess was one, of having "made a compact with the devil." "Have you ever seen the devil?" asked De La Reynie of the duchess in the course of her examination. "Sir," said she, "I see him now; he is very ugly, very stupid, and is disguised as a councillor of state." The incident, and the scene of it, throw light on many other things, in the France of 1680, than the quickness of a woman's tongue.

Sumptuary laws of Louis XIV.

The sumptuary laws still in force, and frequently renewed at this period, gave occasion to innumerable ordinances of police, and were amongst those laws which were most easily abused to the injury of inoffensive persons. That such laws, in any form, should emanate from a monarch whose taste for ostentation and extravagant expenditure amounted to mania, is but a proof the more how strikingly near together were the periods of ripeness and rottenness in the tumid monarchy of France.

De La Reynie was succeeded by the Marquis of Argenson, who was lieutenant-general from 1697 to 1718. In his dealings with the remnant of the Protestants, he presented a marked contrast to his predecessor. He was succeeded, within four years, by Machault d'Arnouville (June 1718 to 1720); by the Count d'Argenson (January to July 1720); and by Taschereau de Baudry (July 1720 to April 1722). The administration during this period presents little occasion for remark; but on the return of the Count d'Argenson, in April 1722, an active crusade was undertaken against the press. No book or writing was to be published without preliminary censorship by the police. The whole trade of printing was already under strict regulation, its development limited by law, and its practice hampered by many restrictions. These were now increased and made more stringent. The conditions of the cataloguing, valuing, and selling of libraries, booksellers' stocks, and the plant of printing-offices, were minutely prescribed.[2] It was in this storehouse that the unlucky functionaries of Charles X. sought their precedents.

The lieutenant-general of police from 1724 to 1754.

The succeeding lieutenants-general of police were Ravot d'Ombreval (1724–25), René Hérault (1725–39), Feydeau de Marville (1739–47), and Berryer (1747–54). The first of them has the miserable distinction of having been almost wholly engrossed with the affairs of the Protestants. Hérault effected considerable improvements in the lighting and watching of the streets of Paris. Feydeau de Marville organised himself by some vigorous efforts to check the growth of mendicancy. But no head of police, nor any other functionary in high place, seems to have reached, even in idea, some of the principal causes of the evil. Trade continued to be hampered by the old restrictions, and mere palliatives, often severe in their operation upon wretched but inoffensive people, some of whom could not find work, however earnest in the search, were resorted to, as of old.

The police of mendicancy.

When, as we have seen, the work-house and hospital system was first established (1657), the mendicants who were housed were from 5000 to 6000 in number. Every one that worked was entitled to a third of the produce of his labour. But in 1720 able-bodied mendicants were no longer received. They were sent back to their respective townships. Almsgiving was forbidden. Inhabitants of Paris were prohibited from lodging any persons of whose means of livelihood no satisfactory account could be given to the police. The provinces soon complained. A new system was then tried in the capital by opening registers for able-bodied paupers, who were brigaded, and employed on roads and other public works. But the evil outstripped the remedies. It had been deeply rooted in the days of Louis XIV., a period as remarkable for the multiplicity of its laws and regulations respecting the poor as for the profuse squandering of the national resources. In the succeeding reigns the "standing army of misery," as a recent historian has called it, became more formidable still. In 1767, according to the minister Necker, 50,000 mendicants were actually taken into custody.[3] At this period the receptacles for such captures throughout the kingdom were but thirty-three in number. Incredible as such a statement would seem to be on less sufficient authority than that of Necker, there is yet conclusive evidence that, ten years later, after a series of deficient harvests, mendicancy had enormously increased.

De Sartine's administration of the police department.

At the time of which Necker writes, De Sartine was lieutenant-general of police, having succeeded Bertin, who had filled the office from 1754 to 1759. De Sartine remained at the head of the police until the 30th August 1774. He was a man of considerable ability, but will long be deservedly gibbeted in history for having prostituted his office to the basest uses. The systematic reports by which he ministered to the crapulous tastes of Louis XV. give us a view of kingcraft at its lowest possible pitch of degradation. Such a court, in juxtaposition with the "army of misery," might well be the prelude to a "reign of terror." If other proof be wanted, it will be found in the details of that Ordonnance d'Instruction Criminelle of August 1670, which remained in force, with very slight modification, at the eve of the revolution. Preliminary torture, perforation of the tongue and of the lips, mutilation quartering, burning alive, and breaking on the wheel, will all be found prescribed in this memorable edict, coupled with a provision that the judge might increase the punishment enacted, if he thought fit so to do.[4]

The Ordonnance d'Instruction Criminelle.

De Sartine's term of office is also marked by that calamity at the public celebration of the marriage of the Dauphin (afterwards Louis XVI.), which seems to have been partly caused by the conflict of authority between the lieutenant-general and the provost of trades (*prévôt des marchands*), and which certainly led to a better demarcation of their respective functions. The accident cost the lives of a hundred and thirty-two persons.

The inquiry before the Parliament of Paris into the causes of so lamentable a disaster, resulted in divesting the provost of all share in the control or responsibility of public festivities, except within the town-hall and on the river. The lieutenant-general alone was made answerable for all needful precautions on such occasions beyond those limits.[1]

Changes in the functions of the lieutenant-general and the provost.

The lieutenancy of the successor of De Sartine, M. Lenoir, was marked by very different characteristics. His first tenure of office lasted but a few months, Turgot having replaced him by a follower of his own, Remond d'Albert, early in 1775. But the fall of that eminent minister led to Lenoir's resumption of office in 1776, and he retained it until August 1785. The improvement of the public markets, and the better lighting, watching, and cleansing of the streets, were among the unostentatious but effective labours of this officer. No such vile scandal as the reports of De Sartine can be alleged against Lenoir; but the monstrous abuses which placed the powers of the police at the disposal of private vengeance and family hatreds were as rife as ever. Temporarily checked under the ministry of Malesherbes, that of the Count of Vergennes gave them back their full swing; to the content even of that marvellous "*ami des hommes*," the old Marquis of Mirabeau, whose chief complaint against the police (the strings of which few men had pulled so frequently), was, that "the ruinous expense of commissions of this sort is frightful."[2] Of Lenoir's successor, M. Thiroux de Crosne, nothing very notable seems to be recorded, save the significant manner of his resignation.

Police organization at the outbreak of the Revolution.

The electoral committee sitting at the town-hall amidst its multifarious labours on that famous 14th of July, nominated a town-council, consisting of sixty members, and divisible into six sub-committees, to one of which the business of police was specially confided. The administration thus improvised speedily submitted to the National Assembly a decree, which it adopted, and which, with the king's sanction, was promulgated on the 6th of November, under the title of *Letters-Patent on the Provisional Police of Paris.* When it is perceived that by these letters-patent the duties of this department were distributed among *sixty* petty committees (under the general authority of the municipal body) it will not be surprising that as early as June 1790, the arrangement was considerably modified. The mayor of Paris and the sixteen "administrators," who are first named in the new law as members of the municipality were formed into six executive committees, one of which became the "committee of police." The primary assembly, however, of each of the forty-eight sections into which Paris was divided, exercised certain minor functions, resembling, as it would seem, those of the former commissaries. But it need hardly be said that, after a very brief period, duties of police occupied little of the time either of assembly or of committee.

After the 9th Thermidor (27th July 1794) the National Convention vested the control of the various branches of police in a committee of twenty members, afterwards reduced to three, which became, under the constitution of the year III., the central executive,[3] and retained its authority until the creation of the prefecture of police in March 1800. From this last-named period may be dated the organization of the French police as, in substance, it now exists.

Definitions
of the du-
ties of po-
ice as laid
lown by
he Na-
ional As-
embly.

The definition of the objects and functions of police, as previously laid down in a law of the National Assembly of the 16th and 24th August 1790 (division xi, Des juges en matière de police) remained in force. It runs thus:—

"The objects of police intrusted to the vigilance of the municipal officers include—

"1. All that concerns the safety and convenience of traffic in the streets, quays, squares, and highways; in the cleansing and lighting of the city; in the safe repair of dangerous structures; and in the removal of public nuisances.

"2. The repression and punishment of offences against the public peace, such as affrays, riots, and disturbances in the streets and other public places.

"3. The maintenance of good order in fairs and markets, at public festivities, and in places of public resort, such as churches, coffee-houses, &c.

"4. The inspection of weights and measures; and precautions for insuring the wholesome condition of articles of food exposed for public sale.

"5. The prevention by suitable precautions, and the mitigation by needful assistance, of accidents and calamities, such as fires, epidemics, contagious cattle diseases, and the like.

"6. The duty of obviating or remedying casualties resulting from the acts of lunatics or of dangerous animals.

"7. The supervision of theatres and other public amusements."

The principles thus laid down still form, professedly at least, the basis of police intervention in the matters which they cover. They were further developed when the official organization of the department was settled by the consular decree of 1800, the main provisions of which are as follows:—

Consular regulation of the department of police (1800).

"The prefect of police shall discharge his duties under the immediate authority of the ministers; shall correspond directly with them in relation to matters which lie within their respective functions; he may republish from time to time the police laws and regulations, and may frame and issue directions to insure their execution.

"His duties shall include the delivery of passports, of residence licenses (*permis de séjour*), and of tickets of security (*cartes de sureté*); the repression of begging and vagrancy; the supervision of public-houses and of prostitutes; the dispersion of crowds; *the police of religious worship, of printing, and of bookselling;* that of theatres, of powder-mills, saltpetre-works, and storehouses of arms, and the pursuit of deserters; that of the highways, of public health, of fires and inundations, of river accidents, of the exchange, of commerce, of taxes, of the food markets, and of prohibited wares; and the protection of public monuments." And to this list, long as it is, is added an *et cetera.*

"It shall also be his duty to regulate the expenses of officers of health and of veterinary surgeons, the removal of sick persons and of corpses, the recovery of drowned persons, and the pounds or green-yards (*les frais de fourrière*).

The defrayment of police charges.

"The prefect shall charge the costs of his department on the revenue of the commune of Paris; his budget shall be presented to the town council, and have the sanction of the home minister.

"The commissaries of police and of the exchange, the inspectors of highways and wharfs, and peace officers of all kinds, are placed under his orders, as is the National Guard on due requisition. Finally, the entire control, under the home minister, of the lighting and cleansing of the city is vested in his hands."

In the following year the district assigned to the prefect of police was enlarged, by being made co-extensive with the department of the Seine, with the addition of the communes or townships of St Cloud, Sevres, and Meudon, which form part of the department of the Seine and the Oise.

During the fourteen years which elapsed between the

The prefecture of police under Napoleon.

Administration of the Paris police by M. Pasquier.

establishment of the new prefecture and the first abdication of Napoleon, the office was filled by two prefects only; namely, by Count Dubois from March 1800 to October 1810, and by Pasquier (afterwards the chancellor and Duke Pasquier of Louis Philippe, but better known as "Pasquier the Inevitable"), from October 1810 to May 1814. The tenure of each of these officers was marked by a signal public disaster. It was during the prefecture of Dubois that the terrible calamity at the Schwarzenberg palace occurred in the emperor's presence, and it led to the prefect's resignation. His successor was of a family long eminent in the legal magistracy. The father of M. Pasquier, a counsellor of the Parliament of Paris, had perished in 1794 on the revolutionary scaffold. To the lot of his grandfather, more unhappy still, it had fallen to take a leading official part in the legal murder of Lally. A more remote ancestor, as advocate-general under Henry IV., signalized himself by his resolute curbing of the Jesuits.[1] But no incident in a remarkable pedigree seems to have approached for singularity that strange event which saw the prefect of police, at a moment of entire apparent tranquillity, surrounded in his own house (13th October 1812), and hurried, without a struggle, into one of his own dungeons. Ridicule, however, was M. Pasquier's chief penalty for having suffered himself to be so surprised. The weight of the master's anger at this "political debauch" (so Napoleon designated it) fell on Frochot, prefect of the Seine. Pasquier retained his office until the 13th May 1814.

The police under the Restoration.

The first prefect under the Restoration, but with the altered title of Director-General, was M. Beugnot, a converted Bonapartist, who resembled his predecessor in being a favourite butt of the Paris wits, although in little else. The cause in his case was a stringent regulation respecting Sabbath observance, which he issued shortly after entering on his functions; and speedily followed up by a sort of manifesto on the duties of his department, wherein he compared the police to a "drop of oil," which, duly applied, kept the springs of government from rusting.[2] Count Beugnot held the directorship but a short time, and had a crowd of successors. In the year 1815, indeed, the police of Paris was administered by six successive directors or prefects. The most notable of these was M. Decazes (afterwards duke, and grand referendary of the Chamber of Peers), who in this capacity had the ill-omened task of arresting and examining Labedoyère and Ney. From the prefecture (the old title had been restored after the Hundred Days) Decazes passed to the ministry of general police, of which we shall have to speak presently.

The prefecture of Gisquet, 1831–36.

From the end of 1821 to the end of 1836 there were ten prefects. The administration of M. Gisquet, the last of these ten, was on many accounts remarkable. Characterized by ability, firmness, and power of combination, he made himself a very formidable antagonist to the republicans and oppositionists of all shades. But he overdid his part. Owing his appointment entirely to the favour of Casimir Perier, he permitted his anxiety to carry out that minister's policy to lead him into acts, or into the toleration of acts by inferior agents, that were directly provocative of the crimes it was his duty to prevent. The minister's policy was of that dangerous kind which thrusts forward pretensions beyond its strength. He was, it is true, opposed not only by men who were combating for rational and responsible liberty, but by others who were striving with might and main to bring chaos back again. Such opponents mistook reckless turbulence for political courage, and heated their imaginations until any sort of weapon seemed a fair one, so long as it was to be used against the powers that were. Gisquet's most honest acts of duty were doubtless sometimes distorted into crimes. But with all due allowance for the violence of party passions, it remains certain that the functions of police were grossly abused.

The police and the press under Louis Philippe.

M. Gisquet has, indeed, under his own hand proved the essential points of his assailants' case. When he entered on the prefecture, he found a police prosecution pending against two journals—*Le National* and *La Tribune*—for having charged the authorities with "brigading and paying bludgeon-men," in 1831, on occasion of the anniversary of the taking of the Bastille. The defendants pleaded that the truth of the charge would be substantiated by certain reports addressed to the prefect on the 13th and 14th of July. The tribunal (*Cour Royale*) decreed that those reports should be produced. When summoned to obey this decision of a court of judicature, pronounced in strict conformity with the code, M. Gisquet refused obedience, assigning as his motives "that such a production would have the inconvenience of acquainting the enemies of order with the means of repression at the disposal of government; and the danger, more serious still, of revealing the names of certain secret agents, who, by such an act, and in direct breach of the compact made with them, would be handed over to the hatred and vengeance of their enemies."[3] *The decree was neither annulled nor enforced;* or, in other words, the prefect of police was placed above the law.

Such facts and such arguments, synchronizing as they did with the violent straining of the law against the press on every possible occasion, might well elicit from Armand Carrel his memorable protest:—"It shall not be said that a system which could institute the innumerable and absurd prosecutions for which our lawyers blush; which could plan the piecemeal confiscation of our property by fines and costs; a system under which writers are branded, whilst yet untried, by being coupled with swindlers, or are quietly killed off by the pestilential miasma of St Pelagie, may aggrandize itself yet more by incorporating the 'jurisprudence of the self-evident fact' (*jurisprudence du flagrant délit*). . . . *We* should be guilty if we suffered it. . . . . The life of a man slain furtively at the corner of a street, in the tumult of an insurrection, may be counted a small affair; but the life of a man of honour, murdered in his own house by M. Pèrier's sbirri, whilst resisting in the name of the law, would be much. His blood would cry for vengeance. If the ministry is daring enough to play for such stakes, it may fail to win." That such a man as Carrel should have the opportunity of writing thus within a year or two of the foundation of the "monarchy of the barricades," is a small fact which enfolds as much of history as do many large volumes that bear the name. M. Gisquet's defence of his administration is a book of remarkable ability, and it extends to four volumes, but the reader will seek in vain, from end to end, for an answer to Carrel's description of the political police of 1831–32. Nor will it in 1858 need any arguments to prove that the significance of these bygone events did not cease with the monarchy of the Orleans branch. We have recently seen an eminent statesman standing at the bar of a police court to answer charges based upon repressive laws dating from the worst days of the Restoration; and have seen him condemned (for an act which has made his name illustrious wherever liberty is valued) by a sentence involving the possibility of transportation like a felon. The names are changed, but the story is the same. The end, however, is not yet.

The municipal duties of police under the administration of Gisquet.

If we turn from the police of politics to the region of municipal affairs, the prefecture of M. Gisquet presents many commendable features. He has himself described this municipal portion of the duties as employing nineteen-twentieths of the staff, and, if fully attended to, at least

French Police.

ten hours daily of the prefect's time. But be this as it may, there is no doubt that he found leisure to make important ameliorations in matters of public convenience and of public health. He had, from his first entrance into office, the monition of the swift-coming cholera.

One of the many secondary incidents of the three days of July which appealed impressively to the eye in the streets of Paris for a long time afterwards, was the enormous encroachment of stall-keepers on the streets, quays, and bridges. The number of these was reckoned in 1831 as ranging from 25,000 to 30,000, the suppression of which would seem to have needed an army of police; yet some considerable approach to such a result was obviously essential to the safety and salubrity of the streets, and to the satisfaction of the reasonable complaints of rent-paying and tax-paying shopkeepers. M. Gisquet set to work, ingeniously enough, by instituting a series of inquiries among the stall-keepers themselves, the scope of which they could not appreciate, but which had the effect of putting many of them on the side of the police. Beginning by the expulsion of those who were not domiciled in Paris, and then of those who had learnt a trade, and so on, he gradually reduced the number to little more than one-tenth of its previous extent, without uproar, and under conditions which seemed to ensure that the authorized were in a large measure the deserving.[1]

In like manner, important improvements were introduced into the management of the markets; the police of the river, the wharves, and the canals; and the lighting and draining of the city. Some injurious monopolies were suppressed, and some needless interferences with trade, compensated by no adequate public service, were terminated. By using a wise discretion in such matters, M. Gisquet was the better able to deal vigorously with crying abuses in respect to the adulteration of food. So gross were some of those which he had to suppress, that the narrative forms a notable chapter in the annals of mercantile roguery.[2]

Staff of the Paris prefecture.

The extent and cost of the staff attached to the prefecture of police under the government of Louis Philippe may be briefly indicated thus:—

Divisions.	Specific Functions.	No. of Persons employed.
PREFECT'S OFFICE	Correspondence; reports; registration; foreign refugees	19
SECRETARY'S OFFICE	Framing of regulations and public announcements; archives; police appointments and pay; public festivities and amusements	30
CRIMINAL AND PASSPORT DEPARTMENT	Arrests and preliminary examinations; supervision and inspection of prisons, houses of correction, and penitentiaries; supervision of criminals at large, and of vagrants; records of criminal jurisprudence; delivery and *visa* of passports; matters relating to lodging-houses	323
MARKETS, PUBLIC BUILDINGS, AND PUBLIC HEALTH DEPARTMENT	All matters relating to the cleansing, lighting, and draining of Paris; survey of dangerous structures; street and highway traffic; provisioning of the city, and matters affecting public health	425
ACCOUNTANT'S DEPARTMENT	Accounts of receipts and expenditure	12
WATCHING DEPARTMENT	Patrol; nightly watch and detective department	...
COMMISSARIES' DEPARTMENT	Local inspection of the forty-eight quarters of Paris; intermediate agencies between the central prefecture and the local application of its orders	211
Porters, messengers, and menial servants		60[3]

ice con- ing rds.

At this time there were also attached to the prefecture a Consulting Board of Health, consisting of eighteen physicians, chemists, and apothecaries; a Consulting Board of Architects, composed of thirteen persons, professionally conversant with building; and a Medical Board (ten in number) specifically employed in the inspection of prostitutes.

The strength of the watch and detective department cannot be accurately stated; doubtless for reasons which hinge upon the intimate connection between the police of ordinary crime and that of political subserviency. On the much-debated question of "secret agents" M. Gisquet has a great deal to say. He shows very convincingly that a police must be open to information; and that information may be given from good motives. He shows just as clearly, although without intending it, that the ramifications of the secret service are so complex, its disguises so multifarious, and its social leprosies so spreading, that a writer who could much exaggerate them must be endowed with uncommon gifts.

B get of th police n er L is Phi- li e.

When M. Gisquet entered on his functions (15th October 1831), the expenditure of the prefecture, so far as it was charged on municipal funds, amounted to nearly eight millions of francs (L.333,330); the staff was considerably increased in several departments during his administration, but was pruned in others of less importance, and was kept well in hand. When he quitted office (6th September 1836), the expenditure had been reduced to 7,189,500 francs (L.299,562); the receipts from market-dues, and other like sources, had been considerably increased; and an improved system of accounts established.[4] In this department M. Gisquet's previous experience as a banker stood him in good stead; and the improvements appear to have had enduring results.

The "Sommiers Judiciaires."

Amongst the new measures introduced by this prefect was, he tells us, the systematic compilation of biographical records of contemporary *politicians*. In the nineteenth century such a compilation must be costly as well as curious, but it does not appear whether the expense of it was defrayed from municipal or from other funds. Another and remarkable collection of records had existed already in the archives of the prefecture for some 120 years. Here are registered the names, identifications, convictions, punishments, or acquittals of every person who, during that long period, had been accused before any tribunal throughout France of crime or misdemeanour, and the utmost pains are taken to continue it in the completest form. In 1833 it had long occupied a standing body of clerks (fourteen in number) and an array of ponderous volumes (400 in number), besides an alphabetical index containing about 500,000 names. Even then it was difficult to consult it, on account of the thousands of *Martins*, *Dubois*, *Dupuis*, &c., with which it teemed. M. Gisquet employed a sufficient staff to copy the whole of these records on slips of card-board, each assigned to one individual. The task was accomplished in four years, and thenceforward two clerks did the work of the previous fourteen.[5] The collection bears the title of *Sommiers Judiciaires*, and is in daily use in the criminal courts. If, however, we may judge from passing transactions, this collection is now (November 1858) in a fair way

French Police.

to include the names of some of the most illustrious as well as of the most degraded Frenchmen.

Here, then, we leave a branch of the subject which is far from being exhausted. The police of Paris is undoubtedly the most remarkable institution of its kind which has ever existed. It would be instructive to trace it further, and to bring it into connection with the recent statistics of crime. That section, however, has still more importance for the present purpose, in relation to our own country; and to treat of it in relation to both countries is here impracticable. But there is another section of the Paris police hitherto unnoticed, which is one of eminent difficulty and delicacy. It must not be passed over without some mention, however inadequate.

Police of female prostitution.

Few things in the external aspect of London strike a Frenchman with more surprise than the audacity with which female prostitution thrusts itself upon the public gaze. The wonder is none the less, even if the visitor be one to whom the corruption of Paris or of other continental cities is no mere hearsay. There, at all events, this scandal has limits beyond which it dares not venture; and vice, whatever its extent, is rarely permitted to insult those who do not seek it.

The police regulation of this opprobrium of civilization dates in France from the thirteenth century. The first steps followed close upon the earnest but futile efforts of St Louis for its total suppression, by the public exposure and ultimate banishment of those engaged in it. Such measures failing of their desired effect, prostitutes were tolerated, but permitted to reside only in certain streets, forced to wear a prescribed dress, and to close their houses at fixed hours.[1] No direct measures appear to have been taken until the fifteenth century against the guiltiest class of all,—the traders in the recruiting of those miserable ranks. In the sixteenth, the curb in this direction was tightened. Procurers and procuresses were pilloried, branded, and then banished.[2]

The assembly of the States-General, held at Orleans in the middle of this century, recommended a revival of the frustrated efforts of the thirteenth for the total proscription of prostitution. Owners of houses in which it was permitted incurred fines equal to three years' rent, and on repeated conviction, forfeited their houses. But the sin was too extensive and too deeply rooted to be thus extirpated. Clandestine prostitution was found to have its special evils; and a tacit toleration, under stringent rules of the old sort, returned. Under Louis XIV. (that portentous legislator against immorality and luxury), asylums were opened under the designations, "Refuge," "Maison des Filles de la Madeleine," and "Maison du bon Pasteur;" and the hospital of the *Salpetrière* was assigned partly as a penitentiary and partly as a house of correction. A swoop was made by the police once a week upon such of the prostitutes as were deemed most disorderly; and these, lodged meanwhile in a house of detention, were brought monthly before the magistrates. Some were discharged, others sent to the Salpetrière, and others to the hospital of Bicêtre for medical treatment. Here we seem to have the beginning of the existing system of periodical supervision.[3]

In October 1831 the number of persons of this sort inscribed on the police registers was 3479; in 1836 it was 3800. About two-thirds of the number resided in houses or apartments which they themselves rented, and nearly the whole of the remaining third in houses called *mâisons de tolerance*, 194 in number. These houses are licensed; and the licenses, it is stated, are never given without "the assent of the neighbours;" by which, we suppose, must be meant that of a definite number (*la permission n'est jamais accordée qu'après un'enquête et qu'avec l'adhèsion des habitants du voisinage*). Its conditions prescribe various regulations as to quietness and seclusion; limit the number of the inhabitants, and provide for the weekly visit of the medical officer. As respects the first-named two-thirds, the condition of inscription on the register is, that they present themselves for a like purpose once a fortnight. M. Gisquet states, as the result of his official experience as prefect, and of his acquaintance with the archives of his department, that, irrespectively of the other results of the system, it has reduced the ravages of disease by one-half within fourteen years.[4]

French Police.

The conditions of registration.

If this part of the punishment of vice were limitable to the vicious, the legislator might have reason to hesitate ere he interposed. But it is otherwise ordained. Nor can it be doubted that a system which may seem, on the one hand, to carry with it an implied sanction of practices which the law of a Christian country must always and utterly condemn, does, on the other hand, present itself as a stigma not less degrading than was the pillory of the fifteenth century, or the open cart of the seventeenth.

Connection between prostitution and crime.

In another of its aspects police intervention appears to be in some measure indispensable. Between the class in question and the predatory classes there is an indissoluble tie. Some sort of supervision lies therefore at the threshold of the pursuit of criminals. The means of detective police have recently been everywhere strengthened, as is well known, by the employment of photography. But a quarter of a century ago, a remarkable "gallery of female portraits" had already been commenced at the Paris prefecture, which led to a kind of exceptional police court, by no means to be recommended as a model, to the extent there attained,[5] although, under proper restriction, it may be justifiable and salutary.

Than this question of the treatment of prostitution there can be none which presents greater difficulties to the prudent legislator. To thrust it out of sight will no more remove the evil than the closing of the hatches of a ship on fire will save the ship. The experience of Paris in relation to it may offer much to avoid, but can hardly fail to contain something to imitate. The day will come when a thorough inquiry, in competent hands, into the results of that experience, will be a recognised necessity. The problem is to check a growing evil, without, on the one hand, opening a door to new evils, or, on the other, undermining in any way those first principles of morality, for the weakening of which no improvements of police could make amends. And the problem is a pressing one.

The police of the home department of France.

It will have been seen that, under the old monarchy, the police of Paris was intimately connected with that of the kingdom at large. But there has always been a police of vaguer and wider scope, more or less developed according to the tendencies of the government of the day, and more immediately in the hands of the ruling power, whether monarchical or ministerial. Usually this secret police had been attached to the ministry of the home department, and had thus been in the same keeping with the direct control of the rural police of the kingdom. The *gendarmerie*, justices of peace, mayors, sub-prefects, are all controlled by the prefects of departments, who, in their turn, are accountable to the home minister.

The creation of a separate "ministry of police" was the

he minis-
y of po-
e created
the
rectory.

act of the Directory in 1796. Cochon (afterwards *Comte de l'Apparent*) was the first regular minister of the new department, although Merlin of Douay appears to have been its chief organizer. M. Cochon had to maintain a hard struggle. The conspiracy of Babeuf and his fellow-socialists was followed closely by that of Lavilleheurnois and his fellow-royalists. The latter had paid the minister of police the undesirable compliment of inserting his name in the cabinet they proposed to form, had they succeeded in restoring the monarchy. This circumstance increased the animosity of his enemies, both in the councils and in the Directory, and hastened his expulsion from office. Lenoir de la Roche for a very brief period succeeded him. Sotin was made minister of police on the eve of the "18th Fructidor," to the success of which he contributed. In 1799 Fouché obtained the department, with which his name is now historically identified.

e minis-
y of po-
e under
poleon.

Fouché began in the spirit of a thorough-paced demagogue. His long familiarity with political clubs and popular insurrection supplied him with formidable weapons wherewith to destroy his old friends. No denouncer of anarchy or apologist of power could outstrip his zeal in the service of the Directory, until sudden enlightenment showed him that the Consulate would be more for the public good. His assistance on the 18th of Brumaire was rewarded by his continuance in a ministry, the functions of which he took care to complicate in a fashion that might well abate the courage of an aspiring rival. Napoleon never placed real confidence in him. Fouché had just enough of honesty to save him from taking any useless pains to disguise his egotism, or to varnish the innate coarseness of his manners. But he was too able and too useful to be cashiered. The experiment made in that way after the peace of Amiens was of short duration. The Pichegru conspiracy restored the ministry of police, which for that brief period had been incorporated with the ministry of justice, under the special direction, however, of Réal, who was virtually independent of the minister, and placed Fouché again at its head. But Napoleon took care to assist the restored minister by attaching to his department certain counsellors of state. A special police was also established, under the inspector-general of gendarmerie, who had to communicate directly with the emperor. Fouché's second ministry did not last long, and had a stormy close. His third ministry began on the morrow of Napoleon's return from Elba, and the *services* he rendered led to his retention of office for a time under the second restoration. The best trait in his history is the exertion he made at this period to lessen the proscriptions, of which the infuriated royalists were then so lavish. He resigned his office at the end of September 1815 (to avoid his dismissal); three months afterwards he was banished by the law of the 6th January 1816.

Decazes, the successor of Fouché, conducted the ministry of police with moderation. He mitigated several of the odious laws of 1815, especially those which fettered the press and multiplied the restrictions of individual liberty. When increasing freedom had its natural result in an attack on the continuance of a police ministry, he resisted the movement; but in December 1818 it was suppressed as an independent office.[1]

II. The Police of England.

Po e of
En land.

The ancient police of England may be dated from Alfred. It grew out of his subdivision of the shires into hundreds and tithings. Every man in England must belong to some tithing (or like division, under another name); the inhabitants of every tithing are collectively pledged for the preservation of its peace and security, and are mutually responsible for the apprehension of every accused person within the district. If the offender take flight into another district, he becomes a man "unpledged," and therefore virtually an outlaw. Whatever we may think of William of Malmesbury's famous story of the golden bracelets, hung by Alfred's order in the public roads, there is conclusive evidence that these rigid preventive measures brought about a state of internal tranquillity that was in striking contrast with previous experience, and in all probability scarcely less in contrast with the changes which ere long ensued.

Saxon laws of frank-pledge.

The hue-and-cry, 3 Edw. I.

Statute of Winchester.

If we pass on to the reign of Edward I. we find the main difficulty complained of as obstructing the peace of the realm to be the lack of effective pursuit of felons. The isolation of districts, after the rigid method of the Anglo-Saxon times, must have soon evinced itself to be a measure, so far as it may have been found possible to maintain it, of which the mischievous exceeded the salutary consequences. The effort now was to increase the efficiency of the hue-and-cry. Thus we find it enacted in a statute of 3 Edward I., that "the whole commonalty be ready and equipped to pursue and arrest felons at the order and summons of the sheriff, and at the cry of the country, as well within franchise as without. (*Purveu est que tuz communaument seind prez et aparaillez al maundement c a la somonse des viscontes ou au cri del pays, de suire e de arester les felons quant mester serra ; ausi bien dedenz frounchises comme dehors*). Ten years later, the statute of Winchester commands that, "in great towns being walled, the gates shall be closed from the sun-setting until the sun-rising; and that no man do lodge in suburbs, or in any place out of the town, from nine of the clock until day, without his host will answer for him; and the bailiffs of towns every week, or at least every fifteenth day, shall make inquiry of all persons being lodged in the suburbs; . . . . and if they do find any that have lodged any strangers or suspicious persons against the peace, the bailiffs shall do right therein." It was further provided that highways between market-towns should be cleared from trees and bushes to a breadth of 200 feet from hedge to hedge; that every man between fifteen and forty years of age should have arms; and that constables shall be appointed to make view of such arms from time to time, and to present defaulters "to the justices assigned, and after by them to the king, and the king will provide remedy."

Keepers of the peace, 18 Edw. I.

This statute of Winchester was again sent throughout England fifteen years afterwards, "to be read and proclaimed four times in the year;" and three knights were assigned to each shire to watch over its execution, as "keepers of the peace." In the 1st Edward II., the keepers were directed to appoint two citizens in cities, two burgesses in boroughs, and two lawful men in every market-town, for the due enforcement of the statute.

Statute of labourers, 25 Edw. III.

By the 25th Edward III. (the "statute of labourers"), justices are to hold sessions four times a year, and at all other times needful for the conservation of the peace; and in staple-towns the mayors and two constables are directed to keep the peace, and to arrest all evil-doers in the staple, for trespass, debt, or breach of contract, and to imprison or otherwise punish them, according to the laws of the staple.

Justices of peace.

As early as the 35th of Edward I., the term "justice of peace" occurs on the Patent Rolls ("*Pur ceo que nostre feal e loial peres de Maulay est entendaunt a nostre service en office de* justice de la pes, *vous mandons*," &c.); but it was not until the 34th of Edward III. that these officers had power to try felons; although their functions had been gradually enlarged in lesser matters by several successive statutes (*e.g.*, 2 Edward III., the "statute of Northampton," c. 3.; 4 Edward III., c. 2). By the 5th Henry IV., c. 10, it is enacted that—"Because divers constables of castles within the realm of England have been by the king's commission appointed justices of the peace, and under colour of such commission they take up people to whom they bear ill-will, and imprison them in their castles, until they pay fine and ransom for their deliverance; it is ordained that no person shall be imprisoned by any justice of the peace, but only in the common gaol, excepting by those lords who have gaols within their franchise."

Borough justices.

In the reigns of Henry VI., Edward IV., and Henry VII., various royal charters conferred upon the mayors and certain aldermen of the principal cities and boroughs, and their successors, the office of justices of the peace within their several jurisdictions. The parochial and township constables formed the only police that existed. As to any remedial measures aiming at the removal or diminution of the causes of crime, no trace is to be found until a period comparatively recent. The main dependence of the legislature appears to have been placed on the tender of impunity to accomplices, and the offer of rewards to informers.

Crown approvers, 3 & 4 Will. and Mary, c. 8.

Rewards to persons apprehending criminals.

Thus, by the 3d and 4th of William and Mary, c. 8, persons guilty of robbery in the highways or fields, &c., who, being out of prison, shall so discover any two offenders as to lead to their conviction; and persons not concerned in the offence who shall apprehend and prosecute to conviction any highwayman, shall receive of the sheriff L.40, within a month after the conviction; and any sheriff making default in such payment is made liable to a penalty of double the sum. If the person seeking to apprehend the robber be killed in the encounter, his heirs or executors are entitled to the reward. The apprehender is also empowered to claim the horse, harness, arms, and money taken with such highwaymen, notwithstanding any vested right in the crown or in the lord of a manor, or any claim by the owners and lenders for hire of any such horse, &c.; the only right saved being that of owners feloniously deprived. The 10th and 11th of William III. extended the provision respecting accomplices to burglary and various other felonies; and a statute of Anne extended the L.40 reward to cases of burglary and housebreaking.

Fielding on the causes of the increase and impunity of crime.

But all these inducements were little operative. The administration of the laws was almost entirely in the hands of unpaid and very partially responsible magistrates. Some of those in London had fallen into practices which gave them the current appellation of "trading justices." The only police-office in the metropolis was that at Bow Street, which had grown up in a casual fashion, under the authority of the secretary of state, and without any parliamentary sanction or support. But it chanced that the necessities of a great writer led him to accept the office of "Bow Street magistrate," at a time so critical as to induce him to employ his powers of authorship, as well as his knowledge of law, in the public service. Henry Fielding took the first steps towards an efficient police by forcing on the attention of the public, as well as of men in authority, what seemed to him to be the causes of the growing evils. "First, with regard to private persons," he says, "there is no country, I believe, in the world, where that vulgar maxim so generally prevails, that what is the business of every man is the business of no man; and for this plain reason, that there is no country in which less honour is gained by serving the public. Secondly, ... so far is the power of apprehending felons from being universally known, that many of the peace-officers themselves do not know that they have any such power, and often from ignorance refuse to arrest a known felon until they are authorized by a warrant from a justice of peace. Thirdly, ... the person of an informer is more odious than that of the felon himself; and the thief-catcher is in danger of worse treatment from the populace than the thief." ("The force of this opinion," he elsewhere adds, "may be seen in the following instance: We have a law by which every person who drives more than six horses in a waggon forfeits as many horses as are found to exceed that number. This law is broken every day, and generally with impunity; for though many men yearly venture and lose their lives by stealing horses, yet there are very few who dare seize a horse, where the law allows and encourages it, when by such seizure he is to acquire the name of an informer.") And, "lastly, as to the reward, ... the prosecutor's title to it is too often defeated by the foolish lenity of juries."[1]

Fielding's plan of police.

The proposal which Fielding laid before the Privy Council, by way of remedy, consisted mainly in the establishment of a paid police force, to be under the orders of the acting magistrate at Bow Street, and to be composed of picked men who had served the office of constable. At this time (1753) there existed in London "a most notorious gang of street-robbers, in number about fourteen, who divided themselves in parties, committed such daring robberies, and at the same time such barbarities, by cutting and wounding those they robbed, in every part of this metropolis, as spread a general alarm through the town, and deterred his Majesty's subjects from passing and repassing on their lawful occasions after nightfall. These outrages induced his Majesty to issue a proclamation, and offer L.100 reward for apprehending each of these violators of the public peace. And though this was humanely intended as a remedy for this dreadful evil, instead of answering the end proposed, it soon begat a greater, by inducing a set of villains to decoy unwary and ignorant wretches to commit robberies, and then to make a sacrifice of them for the sake of the reward, while the real offenders not only escaped justice, but increased their barbarities even to murder."[2] Henry Fielding's new force succeeded in capturing the particular gang referred to at the beginning of this extract, after a desperate struggle, in which one constable and one of the robbers were killed on the spot. Considerable head was made against highwaymen, and many gangs of housebreakers were dispersed.

Contemporary objections to Fielding's police.

The plan had scarcely been initiated, when the rapid decline of Henry Fielding's health forced him to resign his office to his brother, afterwards Sir John Fielding, who followed in the same track with great, though, as it proved, but temporary success. Moderate as were the innovations thus made on the old criminal law, they did not fail to be denounced as a "revocation of the darling and essential privileges of freeborn Englishmen;" and a glowing picture was drawn of the ultimate result of such tamperings with the constitution, when this island "would be no more the seat of liberty; slavery would introduce indolence, indolence poverty, and poverty contempt; freedom, arts, and sciences, would then have their rotation, winging their vagrant flight up the Baltic, shunning their once-loved streams of Ilissus, Tiber, Thames, and Seine, and fixing their residence on the long-neglected banks of the Volga; infusing all their spirit among the rude inhabitants of the North; civilizing the unpolished Muscovite, and giving the descendants of the Czarian family an opportunity of gloriously unfolding their imperial eagle in the very centre of the southern nations, and of becoming the sovereign arbiters of Europe;" and so on, ending with an outline of our familiar acquaintance, "the British lion, ingloriously slumbering in the net of captivity."[3]

English Police.

Ietropoli-an police-ffices esta-lished in .792.

Forty years afterwards, crime had become again so rampant as to necessitate more vigorous measures. By the 32d George III., c. 53, seven additional police-offices were established, each with three stipendiary magistrates (at a salary of L.400 each, afterwards increased to L.600) and two clerks. The magistrates were empowered to determine summarily, in a multitude of cases, respecting offences against the public revenue and game laws, against highway acts, and against the various laws of master and servants; to license and regulate public-houses; to punish vagrancy; to suppress nuisances; to instruct parochial constables in their duties; to issue search-warrants for stolen property; to regulate the billeting and recruiting of soldiers; and to take preliminary examinations in all charges of felony and misdemeanour not specifically provided for. The only power conferred by the act which directly addressed itself to the prevention of crime, relates to the apprehension of persons of ill-repute found in the avenues to public places, under circumstances indicative of an intent to rob. The expense of each office was restricted to two thousand pounds a year.

Colquhoun on the po-ice of Lon-lon, *circa* 1800.

In his elaborate *Treatise on the Police of the Metropolis* (of which the 6th edition was published in 1800), Dr Patrick Colquhoun, one of the magistrates first appointed under the act of 1792, indicates, as the main deficiencies which the experience of eight years had brought saliently out, the want of an entire re-organization of the system of constables, and of an adequate fund for rewarding informers. "If criminals," he says, "at war with the community, are to be detected; if risks are to be run to effect this purpose; if it is to be done, as it must frequently be, at the hazard of the loss of health, and even of life, by watching desperadoes in the night-time; if accurate informations are necessary either to discover where stolen property is deposited, or where the delinquents are to be found, a fund must be provided, or the public cannot be protected."[1]

rganiza-on of the ondon olice at e begin-ing of the resent ntury.

At this period six police constables only were attached to each of the metropolitan offices, making 40 in the whole; 68 other constables were under the orders of the chief magistrate at Bow Street, as patroles for the principal metropolitan roads; 41 formed the civil force of the Thames police establishment (organized in July 1798); 40 stipendiaries were employed in the city of London under the corporation; and there were in addition 843 parochial officers—beadles, constables, or head boroughs—serving without stipend. The nightly watch and patrol comprised in the city of London 803 men, generally aged, often infirm, and the honest among them very frequently half-starved,—their wages varying from 8½d. up to 1s. 6d. for each night; and in the other metropolitan districts (Westminster, Southwark, and part of Kensington included) 1241 men, very similar in age and physical condition, but, in the more opulent districts, somewhat better paid. These watchmen and patroles were under the control of more than 70 different boards or trusts, the powers and procedure of which were regulated by about 120 several acts of Parliament.[2]

he old ghtly atch.

Those who knew London at this period, or during the following quarter of a century, will remember that the turning out of the "nightly watch" was, once in a way, a sight worth seeing, although for quite other reasons than those which are said to have brought Henry VIII. into Cheapside one night to witness a similar spectacle. To connect, in idea, such an assemblage of the halt, the lame, and the purblind, with the terror of thieves and the repression of outrage, required vivid powers of imagination. That crime increased, no statistics need be cited to prove. The establishment of the police-offices, and that, most especially, of the Thames police-office, had produced excellent results; but in the absence both of an efficient executive force and of a central superintending authority, it failed, and could not but fail, to make head against the ever-increasing temptation of augmented wealth and a rapidly-growing population.

Parliamentary inquiries into police.

Repeated inquiries took place before committees of the House of Commons. The utter inefficiency of the existing police force was clearly shown. The necessity of an improved system of licensing and controlling public-houses was proved; and it was made not a whit less apparent that "coffee-shops" may be so conducted as to stand quite as much in need of regulation as do beer-houses. "Another proper call for additional powers to the magistrates," writes a competent witness in 1822, "is furnished by the coffee-shops,—an extraordinary nuisance which has recently risen up in this great city. These places are the resort of the vilest thieves and prostitutes, and have hitherto gone on with impunity, because, as neither beer nor spirits are retailed in them, they are not required to be licensed." The monstrous impunity with which systematic trade in stolen goods was carried on and extended likewise forced itself upon attention. But the inquiries of 1812, 1816, 1817, and 1822 led to little more than an increase in the salaries of magistrates, and gradual accretions to their jurisdictions, as the police acts were severally renewed. On one of these occasions, also, Sir Robert Peel laid down as a formal rule the practice that had been usually but not invariably followed since the days of Lord Sidmouth, of appointing as police magistrates none but barristers.

Sir Robert Peel's Police Act of 1829.

The committee of 1828, however, has left its plain mark in the annals of police legislation, inasmuch as it paved the way for Sir Robert Peel's act of 1829 (10 Geo. IV., "An Act for improving the Police in and near the Metropolis"), by which a large approach was made towards that cardinal point in police reform,—the separation of the incongruous functions of thief-taker and judge, and an effective constabulary force was established under the control of two commissioners. This act, it is true, left many petty, detached, and independent bodies of peace officers in certain districts of the metropolis, irrespectively of the city of London, to which it did not at all apply. And to this extent it contained the seeds of future embarrassment in the proper working of the new constabulary. But if the state of parties in 1829 be borne in mind; if it be remembered how greatly Sir Robert Peel's political position was hampered by the results of his manly conflict for the Catholic Relief Bill, and how imperfectly public opinion was enlightened to the true importance of the police measure, even after all that had been done and said in relation to it, the surprise will rather be, that he effected so much, than that he did no more.

Parliamentary inquiry in 1838 into the working of the new police.

In 1838 the working of the new system came fully under the review of a parliamentary committee. The inquiry amply justified the measure of 1829, and the wisdom of extending it. Notwithstanding the loud prophecies of the worse than Egyptian bondage that was sure to follow so dangerous an innovation, no evidence was forthcoming that liberty had suffered by the suppression of the old watch-boxes, and of the woollen nightcaps by which they were wont to be tenanted. The committee reported its opinion—(1.) That the several constabulary forces (including that of the city) of the metropolis should be consolidated; (2.) That all executive duties of police should be entrusted to the commissioners; (3.) That the police-offices should be so regulated as to assimilate them, more than heretofore, to courts of justice; (4.) That, within the jurisdiction of the Police Act, one magistrate, sitting alone, should be empowered to deal with all cases; (5.) That police justices should be empowered to determine cases of simple larceny up to a value of forty shillings; (6.) That they should likewise be empowered to determine certain petty and constantly-recurring questions of a civil nature, especially affecting the most numerous classes of the population, and not previously provided for; (7.) That a revision of the police districts should be made, with a view to their better adaptation to the growth of the metropolis. There were many other recommendations on points of detail, but those we have cited comprise the matters of chief importance. In the following session bills were introduced in accordance with the principal recommendations of the committee; and again there was an active opposition.

---

[1] Colquhoun, *Treatise*, &c., 6th edit., p. 510.

[2] Ibid., pp. 397, 414.

Maintenance of the separate control of the police within city of London.

The main contest was as to the consolidation of the police of the city with that of the outlying districts. It resulted in the introduction and ultimate passing of a corporation police bill, modelled in its details on that of the government, but retaining the separate control. The city force was to be placed under a commissioner, intrusted with like powers within the city to those which the metropolitan commissioners possessed without it.

The metropolitan police acts of 1839.

The chief provisions of the acts of the 2d and 3d Vict., c. 47 and 71 (the former entitled "An Act for further Improving the Police in or near the Metropolis;" the latter, "An Act for Regulating the Police-Courts in the Metropolis"), carrying into effect the above-cited recommendations of the committee of 1838, from the 2d to the 6th inclusive, give large powers for the pursuit and recovery of stolen goods; for the better regulation of hired carriages, and highways; and for the suppression of nuisances of various kinds. They raise the maximum salary of the magistrates to the sum of L.1200; and empower the Queen in council to alter the number and situation of the police-courts, as well as of the magistrates.

19 & 20 Vict., c. 2 (Feb. 28, 1856).

Finally, by the 19th and 20th Vict., c. 2, entitled "An Act to Amend the Acts relating to the Metropolitan Police," it is provided that one commissioner only shall be appointed after the passing of the act, at a salary not exceeding L.1500 per annum; power is given for the appointment, under the sign-manual, of two assistant commissioners, each at a salary not exceeding L.800 per annum; and it is enacted that all powers theretofore vested in the joint commissioners shall thenceforth be exercised by the sole commissioner.

Present organization and staff of the metropolitan police.

On the 1st January 1858 the metropolitan police force consisted of 17 superintendents, at salaries varying from L.200 to L.440; 140 inspectors, at salaries varying from L.81, 18s. to L.200; 630 sergeants, at weekly pay, amounting, in the lowest class (610 of the 630), to L.63, 14s. per annum, and in the highest class to L.109, 4s.; and 5296 constables, with pay ranging from L.49, 8s. up to L.78 per annum. Both sergeants and constables receive coals in addition to their pay and clothing, at the rate of 40 lb. weekly to each married man throughout the year, and 40 lb. weekly to each single man during six months, and 20 lb. weekly during the remainder of the year. The aggregate expenditure for pay and clothing amounted to L.349,315, 19s. 3d. The total expenditure of the department during the year ending 31st December 1857 was as follows:—

I. *Metropolitan Police Force*, 1857.—*Expenditure.*

Office salaries and expenses (including law charges, L.191, 3s. 6d.)……	L.11,367	0	8
Pay, clothing, and equipment of the force……	349,315	19	3
Retired allowances, and contribution to superannuation fund……	28,510	1	7
Medical and funeral expenses……	3,087	7	8
Horses and vans……	8,502	2	11
Police-station and section-houses……	18,779	16	10
Fuel and light……	13,649	18	6
Survey and protection of dangerous structures…	2,609	14	7
Miscellaneous expenses……	8,389	19	1
Total expenditure……	L.444,212	1	1

Establishment and staff of the metropolitan police-courts.

At the same period—namely, the close of 1857—the establishment of the metropolitan police-courts consisted of one chief magistrate at L.1500; 22 magistrates at L.1200 per annum each; 23 clerks, at salaries varying from L.75 to L.500 per annum; and 52 ushers, jailers, and messengers, at wages averaging L.82 per annum. The total expenditure on account of the courts, for the year, was as follows:—

II. *Metropolitan Police Courts*, 1857.—*Expenditure.*

Salaries and wages……	L.39,376	0	4
Retired allowances and pensions……	4,882	1	3
Purchase and repair of premises, rent, taxes, &c…	6,118	17	2
Fuel, light, and miscellaneous expenses……	1,883	18	6
Police Gazette……	3,142	9	9
Total expenditure……	L.55,403	7	0

Portion of the metropolitan expenditure borne by the Treasury.

When the police force was first organized (under 10 Geo. IV., c. 44), the contribution from the Consolidated Fund, in aid of the police rate, was limited to L.60,000 per annum. This sum continues to be the contribution of the Treasury, as respects the original district. For the extended district a contribution is made equal to one-third of the proceeds of the rate levied on that district.

The police rate of the metropolitan district.

The total sum charged in 1857 (by half-yearly warrants) upon the parishes within the original district was, at sixpence in the pound (upon a rental of L.9,811,926), L.245,298, 3s., to which, as we have seen, L.60,000 were added from the Consolidated Fund; the total sum charged in like manner upon the parishes within the extended or additional district (upon a rental of L.1,822,953) amounted to L.45,573, 16s. 6d.; to which was added from the Consolidated Fund, L.15,191, 5s. 6d.; making in the aggregate L.366,063, 5s.

The smallest contribution by rate, it may be worth while to note, is that of the liberty of Twyford Abbey in Middlesex, being L.13, 6s. (upon a rental of L.532); the largest i that of the parish of St Marylebone, being L.24,984, 6s. (upon a rental of L.999,372).

Special contributions from the Treasury.

Besides the sums which have been specified, there are paid out of votes of Parliament, in pursuance of provisions in the acts of the 2d and 3d Vict., c. 47, of the 17th and 18th Vict., c. 94, and of the 19th Vict., c. 2, the following sums,—viz., to defray the increased charge arising from the addition of the duties of the horse patrol and the Thames police, L.20,000; to defray the salaries of commissioner, assistant-commissioners, and receiver, L.4100; to defray certain superannuation charges, L.4080, 19s. 6d. Other sums received from public offices and departments for special services, severally rendered to them by the police, amount to L.24,701, 16s. 8d.; and like sums received from trading companies and private persons amount to L.8194, 0s. 10d. The total receipts from all sources stand thus:—

Abstract of the total receipts.

III. *Metropolitan Police Force*, 1857.—*Receipts.*

Police rate (6d. in the pound)……	L.290,871	19	6
Treasury……	103,380	5	0
Public departments for special services……	24,701	16	8
Companies and private persons……	8,194	0	10
For conveyance of prisoners……	819	17	7
From owners of dangerous structures……	1,691	2	4
Stoppages from police pay for lodging……	5,218	14	11
Miscellaneous receipts……	687	17	2
Total receipts……	L.435,565	14	0

Metropolitan Carriages Act (16 & 17 Vict., c. 33 of 1853.

By the 16th and 17th Vict., c. 33 ("An Act for the better Regulation of Metropolitan Stage and Hackney Carriages, and for Prohibiting the use of Advertising Vehicles"), the inspection and regulation of public carriages is made one of the duties of the commissioners of police; the certificate of the commissioners being the condition precedent of the licensing of any such carriage by the Boards of Inland

Revenue. The expenses of this department are borne by the board out of the proceeds of licenses, and amounted in 1857 to L.11,828, 15s. 5d.

The receipts of the police-courts during 1857 were :—

IV. *Metropolitan Police-Courts*, 1857—*Receipts.*

From the Consolidated Fund (under 2 & 3 Vict., c. 71, § 11)	L.28,025	9	1
Out of vote of Parliament, 1857–8	30,308	2	10
Fees, penalties, and forfeitures at the various courts	11,291	2	9
Contributions to the superannuation fund	1,112	3	3
Total receipts	L.70,736	17	11

The whole amount received for fees and penalties is paid over to the Exchequer, and the whole expense (L.55,403) defrayed by the Treasury; but of course about one-fifth of the cost of the police-courts is virtually self-defrayed from the former source.

Cost of city of London police.

The total cost of the police force within the city of London was in 1857, L.43,945, 6s. 9d., defrayed from corporation funds. The aggregate number of police of all ranks employed was 552.

Apprehensions, discharges, convictions, and committals.

The number of apprehensions by the metropolitan police, and their results before the magistrates, will be seen by the following comparative table, which comprises (1.) the three years ending 1836, and (2.) the three years ending 1856:—

VI. *Metropolitan Police,—Apprehensions and Results* 1834-36, *and* 1854-6.

Years.	No. of Persons taken into Custody.	No. Discharged by Magistrates.	No. Summarily Disposed of, or Held to Bail.	No. Committed for Trial.	Years.	No. of Persons taken into Custody	No. Discharged by Magistrates.	No. Summarily Disposed of, or Held to Bail.	No Committed for Trial.
1834	64,269	34,499	26,302	3,468	1854	75,614	39,514	30,941	5,159
1835	63,474	32,544	27,817	3,113	1855	68,505	34,850	29,796	3,859
1836	63,384	29,776	30,453	3,175	1856	73,240	36,551	33,451	3,238
Total of the 3 years, 1834–36	191,127	96,819	84,572	9,756	Total of the 3 years, 1854-6	217,359	110,915	94,188	12,256
Yearly average of those years	63,709	32,273	28,190	3,252	Yearly average of those years	72,453	36,971	31,396	4,085

Proportion of discharges to apprehensions.

The proportion borne by the discharges to the apprehensions (1854-56) is, it will be perceived, no less than 51 per cent. in the metropolitan district. This appears to be a much higher percentage than obtains in other districts. In Liverpool, for example (as will be shown presently), it was, on an average of the same three years, 42·8 per cent.; in Manchester, 35·3 ; in Dublin, 31·4 per cent.

Degree of instruction of persons apprehended.

The subjoined table shows the degree of instruction, as far as could be ascertained by the police functionaries, of the whole number of persons taken into custody within the metropolitan district in the year 1856 :—

VII. *Metropolitan Police,—State of Instruction of Persons taken into Custody*, 1856.

Could neither read nor write	15,482
Could read only, or read and write imperfectly	53,540
Could read and write well	3,837
Possessed of superior instruction	381
Total number of persons apprehended	73,240

Classification of offences within metropolitan district.

Any elaborate classification of the cases included in the preceding tables would require space not here available; but limiting the statement to the summary convictions and the committals of 1854-56, the nature of the offences may be thus briefly indicated :—

VIII. *Metropolitan Police,—Class of Offences for which Prisoners were Committed for Trial*, 1854–6.[1]

Nature of Offences.	1854.	1855.	1856.	Total of Three Years.
1. Offences against the person	266	241	224	731

---

[1] We have abridged these returns from the voluminous and valuable tables published in *Miscellaneous Statistics of the United Kingdom, presented to both Houses of Parliament* (1857) pp. 84–88.

Ancillary duties of metropolitan police.

The number of fires reported by the metropolitan police during the same three years was 1468, and the number extinguished by the force before the arrival of the engines was 115; the number of public-houses and beer-shops summoned was 3441, of which 2666 were convicted, and 775 dismissed; the number of stage and hackney carriages, carts, and waggons summoned was 9362, of which 8184 were convicted, and 1178 dismissed.

Borough and town police of England.

Under the Municipal Corporations Act (5 and 6, Will. IV., c. 76), or under local acts, 171 cities, boroughs, and towns in England and Wales maintain a police force, which, on the 29th September 1857, amounted in the aggregate to 5251 officers and constables of all ranks. The city or borough police is a charge upon the borough funds, aided in a majority of instances, by a police rate. One-fourth, however, of the cost of pay and clothing is repaid from the public revenues to all cities and boroughs having a population exceeding 5000, and to all boroughs of lesser population, provided the police force be amalgamated with that of the county; but such repayment is in all cases subject to the certificate by the home secretary, upon annual report from her Majesty's inspector, that the force maintained is efficient as respects both its numbers and its discipline.

Cost of the borough police.

The total cost of the borough police throughout England and Wales in 1857 was L.337,853, 2s. 11d., of which sum L.60,970, 8s. 4d. was borne by the Treasury. The largest local force—both numerically and in respect to population—is that of Liverpool, which is composed of 956 officers and men of all ranks, and is in the ratio of one policeman in every 393 of the population. Then follows Bristol, with 301 police, or one in 459 of the population. Manchester comes next, with a force of 554 persons, or one to 547 of the population. At the opposite extremity of the scale come some of the smaller manufacturing towns of Lancashire and Northern Cheshire, the Cornish boroughs and some quiet easy-going towns in various parts of the country; as, for example, Saint Albans in Hertfordshire, which has 7 policemen to a population of 49,000; and Beverley in the East Riding of Yorkshire, which (if the judicial statistics presented to Parliament in 1858 are accurate) has but one such functionary in 8915 of population. But this great variety of condition in respect of police will be best appreciated if we tabulate a few examples out of the official statistics of the 171 towns and boroughs which are before us:—

Relative strength of borough police.

Police certificate system.

The blanks in the last column of this table indicate that in the case of those boroughs respectively the state of the police force was unsatisfactory to the inspector, and that the certificate of the secretary of state was in consequence withheld. There can be no doubt that this plan of government inspection and certificate is the hinge on which the efficiency of the borough police mainly turns. The certificate is often granted conditionally, when the deficiencies pointed out by the inspector, whose reports are communicated to the respective local authorities, appear to be in the way of remedy. Thus, in December 1857, Sir George Grey, in transmitting Colonel Woodford's report to the watch committee of Salford, states that he had granted the certificate "in the confident expectation that the observations of the inspector as to some defects in the condition and discipline of the borough police force will receive due attention;" on the like occasion, to the watch committee of Newcastle, "trusts that the recommendation of the inspector of a moderate augmentation of the force will receive due attention;" while that of Halifax is informed that the secretary of state "will not feel himself justified in certifying . . . that your police has been maintained in a state of efficiency in point of numbers and discipline for a longer period than from 21st September last" (*i.e.*, twelve weeks of the year); adding, however, that "if your police force is maintained (as he has no reason to doubt), at its present state throughout the ensuing year, he will have great satisfaction in granting the certificate to which it will be fully entitled.[2]

Necessity of government inspection in measures of sanitary police.

Some similar provision for a systematic and efficient government inspection is greatly needed in respect of sanitary measures in boroughs. The owners of what in our large towns is designated "cottage property," have of late years associated themselves for the express purpose of resisting sanitary improvement. In some of the towns which stand most in need of such improvement this class of persons has succeeded in attaining a prominent influence in the town councils. In the municipal elections of November 1858, this influence has been repeatedly observed. By such means, even in large towns like Manchester, sanitary associations, acting upon principles which have had the direct sanction of the legislature, after searching inquiry, find themselves opposed by the local influence of the corporations and functionaries, whose duty it is to further the very measures they impede. Nor is it without precedent to find men placed on committees which have to deal with specific questions of this sort, who are known to have a pecuniary interest in obstructing the due action of those committees, and who are so placed for that express reason. In large and wealthy towns public opinion will, in the long run, be too strong for petty and tortuous interests. In small and poor towns, local opinion stands in much need of being reinforced from without.

Cellar dwellings.

Take, for example, the question of "cellar dwellings," the inhabiting of which is absolutely incompatible with vigorous health, and the bare existence of which, in English towns in 1858, is a proof of the gross neglect in past years of the rudiments of sanitary police. In Manchester some real improvement in this respect has been effected,[3] although not without great difficulty. But how does the case stand in the neighbouring town of Bolton?

In August 1855 it was ascertained that about 6000 persons, or one-twelfth of the entire population of Bolton, dwelt in cellars, the number of which was about 1600. It follows, therefore, that each cellar was tenanted on the average by nearly four human beings. This was the fact in 1855, twenty-three years after the fearful lesson of 1832, repeatedly enforced by other like warnings of later date. The attention of the town council was pressingly claimed to a state of things so dangerous and so disgraceful. It set to work at length, but in a very lethargic fashion. In politer phrase, its members "showed their anxiety to proceed gradually and with caution." In the year 1856 they closed 128 of these places; *in* 1857, *forty-nine; and in* 1858, *thirteen.* At the end of 1858, a "Cottage Owners' Association" interposed in the municipal elections, with the view of securing the return of councillors for whom even this rate of "interference with property" was too rapid. The reader may calculate with little difficulty the period of time requisite for the removal, if left entirely in such hands, of an evil which the law of the country has emphatically condemned, and which a medical member of the town council in question (to whom the honour of effecting the little that has been effected is mainly due), stated, on the professional experience of a long practice, to "involve an immense loss of human life."[1]

mproved elations of lasses in he manu- acturing owns.

The large improvements which have been effected in the borough police of England, under the legislation of the last quarter of a century, are nowhere more striking than in the manufacturing towns of the north, much as yet remains to be done in a like direction in many of them. The rapidity of growth of the manufacturing system; the utter unscrupulousness as to means with which the aggregation of working-people was, in its early stages, urged on; and the then almost entire neglect of moral and educational agencies by a large proportion of those who were suddenly raised from obscurity to influence, had brought about in these towns a state of society which was especially and eminently perilous. Class animosities had become chronic. The masses of the working population saw the functions of of the magistracy and the machinery of the law habitually employed to keep down the weak, and to aggrandize the strong. Disaffection and turbulence could not fail to spread.

The appointment of stipendiary magistrates, and of factory inspectors, in combination with improved means of education, and with a well-ordered police, subject to strict rule and constant publicity, have in this respect completely changed the face of things. If a prosperous Lancashire manufacturer is presented at court, it does not now occur to royalty to inquire, as William IV. did on a like occasion, "Are you quiet in Manchester now?" Royalty has seen with its own eyes that the crowded population of our manufacturing towns can throng their streets on a great occasion with orderly but manly demeanour, uttering no cries but those of loyal attachment.

y police Man- ester.

The police force of Manchester was organized in 1839. For the first four years the number of apprehensions was continually and largely on the increase; and the proportion of persons discharged on appearing before the magistrates was enormous. In 1841, for example, with a population of 235,000, the number of persons taken into custody was 13,345; of whom 10,208 were discharged by the magistrates, 2138 were summarily convicted, and 999 were committed for trial. Of the latter, 824 were convicted and sentenced. The discharged, therefore, were no less than 76·49 per cent. of the number taken into custody, exclusive of 1·31 per cent. acquitted on trial. Such a result could only occur under considerable abuse of the large powers conferred by the Borough Police Act; an abuse, however, which may be partly excused by the novelty of the organization. By zealous attention on the part of the late exemplary chief constable, Captain Willis (now one of the government inspectors of police), a remarkable change has been brought about. The character of the force itself was raised. A certain degree of elementary education was gradually exacted. Great pains were taken to habituate the constables to cautious and discriminating conduct, especially in dealing with charges of a trivial nature, and with such as grew out of disputes and street broils. Intelligent and superior constables were kept constantly on duty at the stations, and were held responsible for strict inquiry into the nature of the charges, before the persons charged were placed in confinement. The importance of a conciliatory bearing towards the inhabitants at large, within the limits of duty, was impressed upon every member of the force. Thus, in 1851, with a population of 303,382 the number of apprehensions was reduced to 4890 (against 13,345 in 1841), and the proportion of cases discharged by the magistrates to 37·50 per cent. (against 76·49 per cent. in 1841). The precise figures of 1851 run thus:—Apprehended, 4890; discharged, 1834; summarily convicted, 2176; committed for trial, 880; convicted and sentenced 722. There can be no better proof of the increased discretion and judgment evinced both by the police constables in taking, and by the sergeants and inspectors in receiving, the persons charged with offences.[2]

The following tables show (1.) the population, police force, apprehensions, and disposal of persons apprehended, within the city of Manchester, for each of the seven years 1851–57 inclusive; and (2.) the degree of instruction of the persons so apprehended during the same period:—

XI. *Manchester Police,—Persons Apprehended, and their Disposal*, 1851–7.

Year.	Population.	No. of Police.	Persons Apprehended.	Discharged	Summarily Convicted.	Committed for Trial.	Convicted and Sentenced.

Offences of publicans.

The following table shows the number of public-houses and of beer-houses within the city of Manchester, and the number of offences reported against them respectively by the police, in each of the years 1854, 1855, 1856, and 1857:—

---

[1] Proceedings of the Town Council of Bolton, Nov. 25, as reported in the *Manchester Guardian*, Nov. 26, 1858.

[2] *Criminal and Miscellaneous Statistical Returns of the Manchester Police*, 1843 to 1857, *passim*.

[3] The return for 1856 is for *nine months* only (ending 30th Sept.) in consequence of that provision in the Constabulary Act which directs the preparation of the returns at the end of September in each year.

XIII. *Manchester Police,—Complaints against Taverns and Beer-Houses*, 1854–7.

	1854.	1855.	1856. (9 mos.)	1857.
Public-Houses:—				
Number in the city................	485	487	489	485
Offences on week-days reported	8	9	5	7
Offences on Sundays reported....	132	110	64	116
Total No. of offences reported	140	119	69	123

	1854.	1855.	1856. (9 mos.)	1857.
Beer-Houses:—				
Number in the city................	1576	1581	1552	1573
Offences on week-days reported	207	169	155	169
Offences on Sundays reported....	659	452	337	576
Total No. of offences reported	866	621	492	745

Each year shows a relative decrease of both classes of houses, as compared with the population of the city. In 1857 the proportion of licensed victuallers to the population was as 1 to 713, against 1 to 691 in 1856; and that of beer retailers as 1 to 219, against 1 to 217 in 1856.

Police statistics of Liverpool.

The table next subjoined shows the total number of persons apprehended by the police of Liverpool, and the results of the hearing of each case by the magistrates, in each year from 1854 to 1857:—

Year.	Total No. of Apprehensions.	Discharged.		Summarily Convicted.		Committed.		Tried.		
		Number.	Percentage to Apprehensions.	Number.	Percentage.	Number.	Percentage.	Convicted.	Acquitted.	Percentage.
1854	25,111	11,529	45·8	13,127	52·2	455	1·8	376	71	1·5
1855	25,689	10,188	39·6	15,053	58·6	448	1·8	352	70	1·4
1856[1]	19,336	8,335	43·1	10,526	54·4	475	2·5	374	92	1·9
1857	24,375	10,914	44·7	12,254	50·3	1207	5·0	870	222	3·6

The Liverpool returns of 1858 (which are before us, but only in an incomplete form) show a decrease of 2386 in the number of apprehensions; and also a marked decrease in juvenile crime, ascribable to the effect of the reformatories hereafter noticed.

Police of the English counties.

We now advert to the condition, as respects police, of the English counties. This branch of the subject was fully investigated by the commissioners appointed in 1836 "to inquire as to the best means of establishing an efficient constabulary force in the counties of England and Wales." The commissioners were Mr C. Shaw Lefevre (afterwards Speaker), the late Sir Charles Rowan, and Mr Edwin Chadwick. They reported in 1839. After an elaborate exposition of the nature, ramifications, and extent of crime with which their inquiry had acquainted them, the commissioners report that "the primary functions of 'watch and ward' . . . . have entirely fallen into desuetude, which is ascribable to the dereliction of the constitutional principle of local responsibility to the supreme executive for the prevention of crime. As a consequence of this state of things, we find private watchmen extensively employed by individuals and by associations for self-protection. . . . . The men hold themselves engaged for the service of those who directly appoint and pay them, and question as little as they can the propriety or legality of any services required of them." Elsewhere they state that "There are upwards of 500 voluntary associations for promoting the apprehension and prosecution of felons, besides very numerous voluntary associations in various parts of the country for the repression of vagrancy and mendicity. Amongst the rules of some of these associations for self-protection, we find rules for mutual assurance by the payment of a part of the loss sustained by depredation. In several of the farmers' associations are rules binding the members, in the case of horse-stealing, to take horse and join in pursuit of thieves, upon an alarm of a theft having been committed;" and they add:—"Hereafter such associations and such rules may be cited to prove that the community in which they arose was relapsing into a state of barbarism."

This aspect of the question was forcibly illustrated in the evidence of the late Rev. Thomas Spencer, of Hinton, near Bath:—"In our part," he said, "if a person's property is safe, it is owing to the good conduct of his neighbours, or to accident, or to the means he may himself use; but it is not owing to any legal protection that he has. I feel that we are, as it were, without the pale of the law; that every man that would be safe must be his own watchman, his own constable, and his own magistrate; that unless he himself takes all the precautions to make his house and property secure, there is no other remedy; that unless he himself shall watch his property, and take up the offender,—shall take him to the constable,—shall order the constable to go with him to the next town, and be at the expense of the constable doing that,—and shall promise the constable to be responsible for putting the man into custody until he can be brought before a magistrate; shall appear before the magistrate, and reason with him, and probably give him an indemnity, if the case be one of doubt; in fact do all the work, the man will escape; whatever be his crime."[2]

State of rural police during the riots of 1830-31.

The commissioners also cited some remarkable circumstances which occurred during the agricultural riots of 1830 and 1831, as showing the utter want of any adequate provision for cases of emergency. For example, "When a report was brought into the town of Newbury in Berkshire, on the 19th of November, that a mob was coming from Brimpton, and special constables were about to be sworn in, the town-clerk and the clerk to the magistrates for the division were quarrelling about jurisdiction; that is, whether the constables should be sworn in for the county, or for the town of Newbury. The Newbury people stuck up for the rights of the town, and would only be sworn before the town magistrates. This fermented a division. *Luckily, the mob . . . . had been beaten and dispersed.*" And in answer to the question, "Were any organized parties sent from the town?" the answer was,—"Parties were sent out, but there was no organization, no system. Those who chose to go, went. In one instance, a party went out, and after they had gone some way out of the town, some of them asked, 'Where are we going to?' It turned out that no one knew, and that each believed he was acting under the guidance of some of the others."[3]

---

[1] Here also the return for 1856 is for *nine months* only (ending 30th Sept. in consequence of that provision in the Constabulary Act which directs the preparation of the returns at the end of September in each year).

[2] *Report of Constabulary Force Commissioners*, pp. 97–99.

[3] Ibid., pp. 106, 107.

eneral re- ults of the ant of an rganized ural po- ce.

Such evidence is but a fair specimen of the general character of the testimony which was gathered, as respects both the repression of ordinary crime and the control of riot. Apart from the ulterior peril of habits of lawlessness, with their possible but indefinite consequences, it must be apparent that such a state of things could not but be costly. In dealing with felonies, every inefficient step at the outset entailed expenses which increased at every subsequent stage, and by leading to frequent impunity, sowed the seed of new crimes; whilst, in dealing with popular commotions, every hour that passed without measures of repression, at once temperate and firm, gave the opportunity for devastations not to be covered by sums that would suffice to maintain an efficient constabulary for many years; to say nothing of the social results, more serious still, which must ever attend on broils in which master is armed against servant, and neighbour against neighbour.

At the date of this inquiry a paid and trained constabulary force had been tried experimentally, and upon a small scale, in many parts of the country. A paid watch, without training, had repeatedly failed. In places where the associations for prevention of robberies were most successful the success was partial, and very frequently had the effect of making the state of things just beyond their limits worse than it had ever been before. Nor was even this degree of efficiency maintained until the establishment of the metropolitan office enabled rural districts, willing to take advantage of the Lighting and Watching Act (3 and 4 Will. IV., c. 90), to obtain the services of practised constables. The change of circumstances which then resulted in many parts of England was strikingly narrated in evidence before the commissioners; as, for example, in the case of Barnet in Hertfordshire, in that of Beckenham in Kent, in that of thirty of the thirty-two parishes which form the Blofield union in Norfolk, and in that of Stow-on-the-Wold in Gloucestershire.[1]

ature and peration the heshire onstabu- ry Act of 29.

But the most extensive trial of a paid constabulary force in rural districts was that which had been made in Cheshire, under the provisions of an act of the 10th George IV., c. 97 ("An Act to enable the Magistrates of the County Palatine of Chester to appoint Special High Constables for the several Hundreds or Divisions, and Assistant Petty Constables for the several Townships of that County"). The whole force established under the act consisted of only three high constables and twenty-four petty constables, and the total expense was L.1274, exclusive of certain fees and perquisites. Small as the force was, petitions were got up in various townships complaining of its cost and "uselessness," and in some townships reductions were made.

At this period a state of things existed in Cheshire, and especially in the hilly districts near the county town, the unadorned account of which reads more like a picture of some of the worst parts of Ireland in their worst days, than of an English county towards the middle of the nineteenth century. Nightly gangs, composed of known persons, yet unbroken for years; individual robbers whom five athletic constables were unable to arrest; habitual plunder, so systematized as to be looked upon by the sufferers as a sort of dispensation of Providence, which it was idle to think of resisting;—such are the features which were conclusively brought out in evidence.[2] Under circumstances like these, it is not surprising that almost all that was achieved by the Local Constabulary Act lay in preventing the districts in which crime was already least formidable from becoming worse; whilst those—the hundreds of Bucklow and Broxton, for example—in which it had never been fairly grappled with, were left at the mercy of events; each farmer hoping that if he did not make himself especially obnoxious to his predatory neighbours, his share in the common loss would be lighter than that of somebody else. It is right to remember that the criminal facilities of some parts of Cheshire were increased by special and temporary incidents; such as those arising from the vexatious character of the old salt duties, from the want of an efficient coast-guard for the prevention of "wrecking," from the long lines of canal, and the like. Nor is it uninstructive to notice that an inquiry which was made into the incubation of certain petitions, not unsuccessful, against an effective increase of the constabulary, elicited the facts, that they had been hawked about by persons having a pecuniary interest in the retention of the old methods, signed by convicted offenders, and actively supported by the keepers of beer-houses. On the whole, two things appeared to be clear: the one that the Cheshire Constabulary Act had failed of its proper effect; the other, that the failure tended to strengthen, not to weaken, the arguments for a county police, composed of trained men, and so controlled as to combine the advantages of uniformity of system with those of local supervision and local responsibility.

The recommendations in which the commissioners of 1839 summed up the results of their inquiry are too elaborate for insertion here, even in epitome. It must suffice to describe the new laws, on the ultimate passing of which the report, and the discussions thence arising, had naturally great influence. Public opinion has not endorsed, nor is it likely to endorse, *all* those recommendations; but that the zeal and ability of the commissioners have laid the country under great obligation, is an obvious fact.

One of the most thoughtful and most incisive of recent writers has told us that whereas our ancestors made laws which have lived for centuries, and promise to live for centuries to come, men in these days do not expect "that any law enacted during the last session will escape without either revision or repeal the next,—beyond which it would be invidious to ask how many members of our legislature have projected their minds."[3] If the reproof was amply justified twenty years ago, what is to be said now? But if piecemeal legislation be excusable at all, it is so in relation to matters of police, in which the new and the old are at once so various and so intimately linked together, that incautious handling might easily destroy whilst seeking only to amend. Here the legislator has to deal with measures in the gross, the whole issue and effect of which, in their particular application, depend on the wide-spread concurrence and hearty fellow-working of all classes of the community. The inventor who should contrive for daily necessities machinery so intricate as to require the constant interposition of the maker to keep it in order, would fail of his object, however admirable the mathematical or mechanical skill embodied in his invention. Frequent amendments in the familiar mechanism would be less embarrassing to the workers. The lawgiver may in like manner overshoot his mark by changes too elaborate and too sudden. In the series of enactments which have at length gradually brought us to a general constabulary system, we have at all events no fault of this kind to complain of.

The rural police acts, 1839-40.

The first step was the passing of the Rural Police Act (2 and 3 Vict., c. 93, amended by the 3 and 4 Vict., c. 88), which empowered the magistrates of any county in England and Wales to appoint chief and petty constables for such counties, in such numbers and under such apportionment to the several districts as they might deem advisable; permitted the magistrates of several adjoining counties to unite in such appointments if they thought fit; and also gave discretional powers for the amalgamation of the police of boroughs with that of the counties in which they were situated or to which they were adjacent.

[2] Ibid., 110–129.

[3] *Guesses at Truth*, by Two Brothers, ii. 10.

These acts, it will be seen, were simply permissive. Essex was one of the first counties to adopt them. Its constabulary was organized in February 1840, and it had the good fortune to obtain a most able and energetic chief constable in the person of Captain J. B. M'Hardy (of the Royal Navy), who had been for many years an inspecting commander of the coast-guard. At this time the new act was in bad odour in many parts of England, and especially, as it would seem, in Kent, Suffolk, Hertfordshire, and Cambridgeshire. The remarkable success which attended Captain M'Hardy's exertions in Essex, at the head of a force composed of 200 men (14 superintendents, 20 inspectors. and 166 constables in three classes), obliged the neighbouring counties, Kent excepted, to follow the example. All these eastern and south-eastern counties were overrun with vagrants, who in large numbers had for years levied a considerable tax on small farmers and cottagers, over and above the amount of casual relief administered to them under the poor-law. In Essex the plan of making the police, under discreet regulations and careful supervision, assistant relieving-officers "for casuals," was tried with excellent effect. This measure checked vagrancy when all other expedients had failed. Hampshire soon followed; and here, as in Essex and the contiguous counties, both crime and vagrancy were remarkably diminished.

During the fourteen years 1840–1853, eighteen English and four Welsh counties adopted the constabulary for the whole of each county; and seven other English counties for parts only. Fourteen English and eight Welsh counties still continued the system of parochial constables.

Superintending Constables Act, 5 and 6 Vict., c. 109.

Conflicting evidence as to the working of this act.

With a view, however, to some increased efficiency in the counties last named, in which the adoption of the Police Act was successfully opposed, the act of the 5th and 6th Vict. c. 109 (Superintending Constables Act), enabled the magistrates of any county to appoint a head constable to each petty sessional division of a county, or to some selected divisions, whose duty it should be to exercise a general supervision over the parochial constables within his district. Much and somewhat conflicting evidence as to the operation of this act was taken by the select committee on police of 1853. Mr Oakley, governor of the county gaol of Somerset, for example, said:—"It increases the evils by inducing the parish constables to set themselves in opposition to the superintending constable. . . . . The superintending constables being altogether uncontrolled, and without supervision, themselves fall into habits which render them unfit for the proper performance of their duties."[1] On the other hand, Lieut.-Col. Clifford, a magistrate of Herefordshire, and chairman of the court of quarter sessions, stated his belief that "the prevention of crime is entirely met by the comparatively small number of superintending constables we now have there;" and that the "superintending constables are as efficient as possible."[2]

Recommendations and opinions of the police committee of 1853.

On this part of the question the committee reported its conclusions as follows:—"The superintending constables have proved useful as police-officers to the extent of their individual exertions and services;" but such an appointment, it adds, "provides no remedy for the inefficiency of parochial constables; and it is the opinion of your committee that any system of police mainly dependent on the aid of parochial constables must prove ineffectual for the protection of property, more especially that of the poorer classes; for the prompt detection and pursuit of offenders, the maintenance of order, and other duties of a police force, for which their necessary avocations and local connections entirely disqualify them."[3]

On the more general question of the working of the rural police acts, the committee resolved:—"1. That the . . . Rural Police Act (from the permissive character of its enactments), has failed to provide such a general and uniform constabulary force as, in the opinion of your committee, is essentially required for the prevention of crime and security of property. 2. That in the districts in which the Rural Police Act has been adopted, its efficiency for the prevention of crime, by rendering the detection and apprehension of offenders more prompt and certain, has been proved to the satisfaction of your committee; that it has tended to the maintenance of order, and to the improved habits of the population; that vagrancy has greatly decreased, and, more especially in combination with the casual relief order of the Poor Law Board, has been in some places almost entirely suppressed; and the effectual protection afforded to property peculiarly exposed to depredation has, in the opinion of owners and holders of land, rendered its occupation more desirable. The adoption of the rural police, therefore, in the opinion of your committee, has proved highly advantageous to those districts, whether tested by moral, social, or economical considerations." The committee further recommend that provision should be made for the equitable adjustment of the police rate between the various divisions of a county, in cases wherein great differences existed as respects the density and employments of the population; that the smaller boroughs should, for police purposes, be consolidated with districts or counties; that the police of the larger boroughs should be brought under like management with that of the adjoining district or county; and that the wisdom of some contribution by government "towards defraying the cost of an improved and extended system of police, without essentially interfering with the local management of that force, deserved the consideration of the House;" and the report concluded with the emphatic recommendation, "That legislative measures should be introduced without delay by Her Majesty's government rendering the adoption of an efficient police force on a uniform principle imperative throughout Great Britain."[4]

County and Borough Police Act, 19 and 20 Vict., c. 69.

In conformity with this recommendation, the act of the 19th and 20th Vict. c. 69, became law three years afterwards ("An Act to render more effectual the Police in Counties and Boroughs," July 21, 1856). Its principal provisions are these:—1. If a constabulary be not already established for the whole of a county, the justices in general or quarter sessions, are to cause the same to be established; if already established in part of a county, then it is to be extended to the residue. 2. Constabulary establishments existing in particular divisions of a county are to be consolidated into a single county police force. 3. But Her Majesty may, by order in council, require separate police districts to be established in counties. 4. Her Majesty in council, on representations from borough authorities, may arrange the terms of consolidation of such boroughs with counties, for police purposes, and may from time to time vary such terms. 5. County constables are to have the like powers in boroughs as are possessed by borough constables in the counties. 6. No constable shall receive any fees for his own use, or shall vote at municipal or parliamentary elections. 7. Powers are given to grant pensions and superannuations. 8. An annual statement as to crime in counties and boroughs is to be made to the secretary of state. 9. Her Majesty is empowered to appoint three inspectors of county and borough police, whose reports shall be laid before Parliament. 10. On due certificate of efficiency, one-fourth of the charge of police pay and clothing in any county or borough is to be paid by the Treasury; but no such payment is to be made to boroughs of less population than 5000. The remaining provisions tend chiefly to the maintenance of existing powers until the new act shall have been brought into full operation. Finally, nothing in the act is to apply to any part of the metropolitan police district, or to the city of London.

Operation of the County and Borough Police Act of 1856.

From this statute, the establishment of a uniform system of police is to be dated. Until the end of 1856 no provision had been made in many extensive districts of the country for the protection of life and property, other than that of the old parochial system, which left those duties to the untrained, unpaid, and frequently unwilling officer, and often failed to equip him with the most essential appliances for the pursuit, apprehension, and safe custody of criminals.

On the 29th September 1857 the county constabulary was returned to the secretary of state as comprising 7301 officers and constables; and its cost, for the twelve months then ended, as L.441,569, 7s. 3d. (a sum which is about L.600 less than the cost of the metropolitan police, and about L.50,000 less than the cost of the metropolitan and city of London police together). It must be noted, however, that as in several counties the police was not fully organized until the year had considerably advanced, this amount will not cover the ultimate annual cost of an average year. The payments from the public revenue towards the cost of the county constabulary amounted during the same period to L.71,112, 1s.

The following table exhibits the establishment, the relative strength as compared with the population, and the total cost of the constabulary in each of the English counties; independently, of course, of all city and borough police, separately maintained. The county returns are not yet complete enough to afford any adequate basis for the exhibition of direct results in respect of the prevention, detection, and punishment of crime:—

The relative strength of the county police ranges, it will be seen, from one in 836 of the population in Surrey, to one in 11,491 of the population in Rutlandshire. Its relative cost also differs considerably, but within smaller limits, depending partly upon the density or sparseness of the population within a given area, the extent and nature of ordinary employment, and the character of the adjacent counties, boroughs, and other districts. Thus, for example, it will be seen that 73 constables in Cumberland cost nearly as much as 173 constables in Cheshire; 114 constables in Berkshire cost L.15,281; whilst 121 in Dorsetshire cost but L.7343.

Total strength and cost of police in England and Wales, 1857.

By way of summary, it may be stated that the total cost of the police force, of all kinds, within England and Wales, during the year ending 29th September 1857, was as follows:—

Description of Police.	No. of Officers and Constables.	Total Cost.			Defrayed by the Treasury.		
County............	7,301	L.441,569	7	3	L.71,112	1	0

Totals.........	19,187	L.1,265,579	18	0	L.235,462	14	4

Summary jurisdiction.

The extent to which criminal adjudication begins and ends as a mere matter of police, in various counties, would, if it could be brought out fully and clearly, afford no mean indication (as one element among many) of their relative position, both politically and socially. The value of such a statement would, however, materially depend on its including an accurate definition of the offences summarily punished. In this particular our English statistics have been seriously deficient. Under the new constabulary law a considerable improvement may be hoped for in this, as in many other respects. Full statistics are the more important, on account of the large extension which many recent enactments have contributed to give to the summary jurisdiction of justices. By the statute of the 7th and 8th of Geo. IV., c. 29, for example, many petty thefts, as of house fixtures, of fish from inclosed waters, of growing fruit or vegetables, and the like, were subjected to fine and imprisonment, without the intervention of a jury; as were also, by another act of the same session (c. 30), other petty offences of the nature of wilful damage and trespass. By the 9th Geo. IV., c. 31, that extensive and somewhat indefinite class of offences, assaults, was brought within the same jurisdiction. Every police act, whether general or local, has made large additions to this category. In like manner, the Juvenile Offenders Act of 1847, and the Criminal Justice Act of 1855, have severally transferred to summary jurisdiction numerous offences which were theretofore punishable as felonies, and liable (up to the year 1853) to the penalty of transportation.

The stronger may be the conviction of thoughtful men that these steps are right and salutary, the more important must it be to bring their consequences under full and enlightened publicity. What, in this respect, the country owes to the newspapers, is incalculable, but insufficient. It needs to be supplemented by the deliberate and systematic summary of results from time to time.

---

[1] *Judicial Statistics of England and Wales* (1858), vi., vii., 3, 4.

Classification of the summary convictions of 1857,

It has been shown already that the police returns of 1857 are unavoidably incomplete. But so far as they go, they give better data than have been hitherto available. Here, however, they can be but briefly noticed in relation to a leading point or two. The total number of cases summarily adjudicated in England and Wales in 1857 was 369,233; the discharges were 135,474; the convictions were 233,759, and may be classified thus:—

Offences.	Total No. of Convictions.
Assaults	44,860
Drunkenness	44,894
Stealing, and attempts to steal	20,577
Vagrancy	18,023
Infractions of police acts	25,913
Infractions of local acts	21,112
Infractions of ways acts	17,382
Infractions of beer acts	11,320
Wilful damage and trespass	13,583
Infractions of the laws of master and servant	9,687
Nuisances	4,328
Other offences	2,080
Total of summary convictions	233,759

and of the punishments for the same.

The punishments in these 233,759 cases may be classified thus:—

1. By various periods of imprisonment (from a week to nine months)	62,293
2. By committal to juvenile reformatories	768
3. By fines	143,463
4. By whipping	525
5. By other punishments	26,710
Total	233,759[1]

Reformatory Schools Act, 17 and 18 Vict., c. 86.

The second item in this table of punishments applies only to a small section of offenders, but it is at once the most novel and the most pregnant consequence of our recent criminal legislation. It dates from the passing, in August 1854, of "An Act for the better Care and Reformation of Youthful Offenders in Great Britain." After reciting that reformatory schools for the better training of juvenile offenders, have been and may be established by voluntary contributions in various parts of Great Britain, and that it is expedient that more extensive use should be made of such institutions, it proceeds to enact that the secretary of state shall, on application, direct the inspection and certification of the inspection of such schools. It is further enacted, that whenever any person under the age of sixteen years shall be convicted of any offence punishable by law, either upon indictment or by summary conviction, it shall be lawful for any court, judge, police magistrate, stipendiary magistrate, or any two or more justices of the peace, or in Scotland for any sheriff, or magistrate of a burgh, or police magistrate, before or by whom such offenders shall be so convicted, in addition to the sentence then passed as a punishment for the offence, to direct such offender to be sent, at the expiration of the sentence, to one of the aforesaid reformatory schools, to be named in such direction, the directors or managers of which shall be willing to receive such offender, and to be there detained for a period of not less than two years, nor more than five years; and such offender shall be liable to be so detained, provided the sentence passed as a punishment shall have been one of imprisonment for fourteen days at least; and it is further provided that the home secretary may at any time direct a discharge. Power is given to the Treasury to defray the costs of maintenance, part of which may be recovered from parents, &c.

Reformatories now under inspection in England.

Within ten days after the passing of this act, the reformatory for boys at Saltley, near Birmingham, was certified in accordance with its provisions. It had been originally established in the town of Birmingham, mainly by the liberality of Mr C. B. Adderley, M.P., with the assistance of Mr Joseph Sturge. At first, great difficulty occurred from the unsuitableness of the indulgent discipline of the voluntary school to the more stringent regulations necessary for inmates received under judicial sentence. But this difficulty has been overcome. At the beginning of 1858 the Saltley school had 39 inmates. The next reformatory certified under the act was that for girls, established and partly maintained by the zealous exertions of Miss Carpenter, at Red Lodge, near Bristol. Here the number of inmates in January 1858 was 57. An adjacent cottage is used as a means of separating the older and more advanced girls, and placing them under the ordinary conditions of free domestic service, previous to their final discharge from the school.

But the most remarkable of these reformatories is that established by Mr Sydney Turner (now the government inspector of reformatory schools), at Red Hill, near Reigate, and of late well known as the "Philanthropic Society's Farm School." Here, in January 1858, 275 boys were maintained, at a nett cost per head of L.25, 4s. The number of boys discharged in the course of 1857 was 149, and the number admitted 129. Of the former, 66 emigrated, at a cost of L.1374, or L.20, 16s. 4d. per head; and 8 were transferred to the Akbar frigate, to be trained for the sea. The institution comprises five schools, each containing on the average 50 boys, and the farm-house containing 20. The total number of English Protestant reformatories in operation at the end of March 1858 was 41, containing 1528 inmates (1287 boys and 241 girls), of whom 180 were free (131 boys and 49 girls), and the remainder were under detention.

Besides these, there are five Catholic reformatories: one in Gloucestershire, one in Leicestershire, two in Middlesex, and one in Yorkshire. The first of these was opened for girls at Arno's Court, near Bristol, under certificate of the 22d April 1856; it contained in 1858, 104 inmates, and formed part of the convent of the "Sisters of the Order of the Good Shepherd." The nuns of that order have another reformatory at Beauchamp Lodge, Hammersmith, which has but very recently been brought into operation. The most extensive and remarkable of these Catholic reformatories is that of the Trappists, designated the "Agricultural Colony of St Bernard's Abbey, near Loughborough." This abbey justifies the old proverb as to the skill of monks in the choice of situations for their monasteries. It is in a beautiful part of Leicestershire, and has a striking aspect. The number of inmates at the close of 1857 was 288, at an average cost of L.23, 10s. per head. "A cheerful, kindly spirit," says Mr Turner, "prevails throughout the establishment, and the whole seems to be in good order." But he is of opinion that, whilst the Fathers themselves justify Napoleon's description of their order ("the Trappists eat little and work much"), they are somewhat disposed to reverse the maxim for the boys, who eat much and work little. Finally, the "Christian Brothers" have two reformatories,—one at Brook Green, Hammersmith; the other at Hulme-on-Spalding in Yorkshire. At the close of the year the former contained 80 inmates, the latter 43. The total number of inmates in the Catholic reformatories in March 1858 was 552 (437 boys and 115 girls), all of whom were under detention.

General results of the reformatory system.

In summing up, generally, the results of the new system, so far as, at this early stage of its operation, "results" can be at all spoken of, the inspector lays great stress on the

---

[1] *Judicial Statistics, ut supra*, p. 16.

General results of the reformatory system.

importance of zealous exertion to place the liberated persons in favourable circumstances for their permanent industry and honesty. Often, he argues, and particularly as regards young offenders from large towns, permanent separation from their old haunts and companions is indispensable; and in such cases emigration offers the best method of provision. But it involves heavy charges, and however economically carried on, must considerably increase the expenditure of the reformatory which resorts to it. The reformatory acts make no provision for the costs of any method of ulterior disposal. Yet, as there is no special limit to the amounts that may be contributed from the rates for "care and maintenance," there would seem to be good economy in making those amounts liberal enough to enable the managers of schools to defray from that source some portion of the expense of that final measure, on the wisdom and foresight of which the profit of the previous steps must mainly hinge. Mr Turner also expresses his strong conviction of the value of that clause in the Reformatory Act which makes the parents of delinquent children liable to contribute towards their support in the schools in which they are detained, although some time must elapse before the principle of parental responsibility can be generally and effectually enforced. Already it has in many cases had the effect of inducing drunken and dissolute fathers to be more sober, and has made the family at home more comfortable, by the pressure exercised in exacting payment (rarely exceeding one-twelfth of the average wages) for the child or children in the reformatory.[1] The number of parents and step-parents against whom authority has been taken for proceeding, from 31st March 1857 to 31st March 1858, is 605; that of persons under contribution on the day last named, 292; and the total amount of contributions already received, L.629, 12s. 8d.[2]

Hitherto little has been done to check the juvenile delinquency of Middlesex and Surrey, where the necessity is so great. But the Middlesex industrial schools will soon be in operation under the special act passed for that purpose; and the Surrey magistrates are about to place a considerable number of the juvenile criminals of that county at Redhill and other reformatories. Meanwhile, the commitments of offenders under sixteen years of age in England and Wales has already fallen from 13,981, which was the number in the year ending 29th September 1856, to 12,501, the number in the year ending 29th September 1857; being a decrease of 1480 commitments, and of at least 600 individual children.[3] This is a fact of good augury. If the industrial training be made efficient, if parental responsibility be in proper cases enforced, and if the management of the reformatories be discreet and frugal, no expenditure for purposes of enlightened police was ever better invested by any community. Nor must it be forgotten that the honour of having laid the foundation of reformatories belongs to a small and unostentatious band of voluntary workers, who have sought no reward save that of witnessing effectual and permanent provision for the continuance of their good work, apart from the uncertainties of casual benevolence and temporary excitement.

III. The Police of Scotland.

Early police of Scotland.

The early history of crime and punishment in Scotland has naturally much in common with that of its southern neighbour, but has also its special and characteristic features. In the long series of acts against vagrancy, for example, we find greater prominence given to the pursuit of gipsies, and also greater severity of treatment in respect of all the offending classes. Identification as "Egyptians" seems to have been often sufficient for capital punishment, apart from proof of specific offences. Thus, there is an act of the Privy Council (10th November 1636) which recites, in respect of certain gipsies who had been arrested and lodged in Haddington jail, that "whereas the keeping of them longer within the said Tolbooth is troublesome and burdensome to the town of Haddington, and fosters the said thieves in an opinion of impunity to the encouraging of the rest of that infamous byke of lawless limmers to continue in their thievish trade, therefore the Lords of Secret Council ordain the Sheriff of Haddington or his deputes to pronounce doom and sentence of death against so many of these thieves as are men, and against so many of the women as wants children; ordaining the men to be hangit and the women to be drowned; and that such of the women as has children be scourged through the burgh of Haddington, and be burnt in the cheek." Even of such less dangerous offenders "as make themselves fools *and are bards*, or other such like runners about," it had been enacted half a century earlier, that, being apprehended, they should be put "in the king's ward and irons, sae lang as they have ony goods of their own to live on; and when they have not whereupon to live of their own, that their ears be cuttit off, and be banished the country; and if thereafter they be found again, that they be hangit." These statutes are followed up by their like at brief intervals for a century and a half. Yet, for a much longer period, the criminal law of Scotland stood in honourable contrast to that of England in two particulars at least. On the one hand, it established a public prosecutor,—in the higher courts the lord advocate, acting by the solicitor-general and four advocates-depute; in the lower courts, the procurator-fiscal. On the other hand (and in the germ, as early as 1587), it assigned counsel to prisoners, provided them with a copy of their indictment, and withheld from the lower courts the power of inflicting any punishment greater than imprisonment.

Burgh police of 1834 and subsequent years.

The first distinctive organization of a police force of some sort appears to date from the year 1725, when the act 11 George I., c. 26, authorized the freeholders of every shire or district "to make an assessment for raising a sufficient fund to defray the charges of apprehending, subsisting, and prosecuting criminals." This power subsisted in the freeholders generally, until, by the 2d and 3d Will. IV., c. 65, it was transferred to a more limited body of freeholders designated commissioners of supply. In the following session (by 3d and 4th Will. IV., c. 46), the Scottish burghs were empowered to establish a system of police, the details of which were amended by the act of the 10th and 11th Vict., c. 37, and by that of the 13th and 14th Vict., c. 33, the latter being entitled "An Act to make more effectual Provision for Regulating the Police of Towns and Populous Places, . . . and for Paving, Draining, Cleansing, Lighting, and Improving the same." The general control of the burgh police maintained under these acts, like that of the police of Edinburgh, Glasgow, and some other large cities having local acts, was in the hands of a board of commissioners elected by the rate-payers.

Rural police of Scotland.

In Scotland, as in England, the rural police of counties was very inadequately provided for by enactments which were merely permissive. The acts of 1839 (2d and 3d Vict., c. 65) increased the assessing powers of the commissioners of supply of any county for purposes of police, but those powers were exerted in but few counties. Where the act was adopted, as in Mid-Lothian, Aberdeenshire, Fifeshire, Stirlingshire, and Dumfriesshire, a county meeting was convened for the election of a police committee

Scotch Police.

which committee determined the assessment and the extent of the force, and appointed a superintendent or chief constable, to whom the control of the force was entrusted.[1] But the police assessment, like its predecessor, the "rogue-money fund," was on landed property exclusively.

Police act of 1857.

Finally, the act of 1857 (20th and 21st Vict., c. 72), entitled "An Act to render more effectual the Police in Counties and Burghs in Scotland," dealt with the question in the spirit of the English act of 1856. It made provision for an efficient force in every county of Scotland, and gave facilities for the consolidation of burgh police with county police. By this statute it is enacted: (1.) That the commissioners of supply of each county shall, at meetings duly convened, proceed to establish, from the 15th March 1858, a sufficient police force for such county; (2.) That the commissioners shall, from their own number, appoint certain persons, not more than fifteen nor fewer than three, who with the queen's lieutenant and the sheriff, shall form the police committee of the county. (3.) That the secretary of state shall from time to time make the needful rules for the government and pay of the force determined on by the commissioners of supply. (4.) That the police committee shall appoint a chief constable, who, with the approval of the committee, shall appoint or dismiss the other constables and superintendents to be appointed for such county; and shall choose a deputy from among them, and who shall have power to appoint additional constables at the charge of the persons applying for them, and for such periods, under due notice, as the applicants may desire. Power is also given to the sheriff to appoint additional constables to keep the peace on public works, at the cost of their respective promoters. (5.) Provisions are made respecting the powers and duties of constables, and for the mutual validity of warrants granted in any of the border counties of Scotland and England; constables are empowered in certain cases to accept bail or deposit; are prohibited from receiving fees to their own use; are disqualified to vote at elections, and are exempted from jury and militia services. (6.) The commissioners are empowered to levy a police assessment upon all lands and heritages, according to the valuation rolls in force under the act of the 17th and 18th Vict., c. 91, "for the Valuation of Lands and Heritages in Scotland;" and to levy it either on the proprietor or the tenant,—the latter being authorized to deduct the amount from his rent, and an exemption provided in respect of all houses and tenements which shall have been wholly unoccupied during the whole period to which the assessment refers. (7.) Provisions are made for the appointment and payment of collectors; for the keeping and accessibility (to ratepayers and other persons concerned) of accounts, and for their annual audit; for three commissioners to be a quorum, and for the preses, in case of equality of votes, to have the casting-vote in addition to his own vote. (8.) Powers are given to the commissioners to grant gratuities and superannuations; to provide station-houses and strong rooms; to form police districts, either at their own discretion, and with the approval of the secretary of state, or in obedience to an order in council. (9.) The commissioners of supply of any county, and the magistrates and town council of any burgh situated in or adjacent to such county are empowered to agree together for the consolidation of their respective police forces; or Her Majesty in council may, on representations from burghs, arrange such terms of consolidation; and the chief constable shall have the general control of the consolidated police. (10.) Annual returns of offences and proceedings are to be sent to the secretary of state; Her Majesty is empowered to appoint an inspector of police; and on certificate of the secretary of state that an efficient police has been established in any county or burgh, one-fourth of the charge for pay and clothing shall be paid by the Treasury,—no such payment being made in the case of any unconsolidated burgh having a population at the last census of less than 5000 persons. (11.) Provisions are made with respect to the recovery and application of penalties duly prosecuted for, within six months of the commission of the offence for which such penalties were incurred. (12.) If within six months after the date of this act (25th August 1857) the inspector shall have reported to the secretary of state that any burgh maintains, out of its common good or from any funds other than assessment, an efficient police force, shall be considered as maintaining a separate police force under a local act. (13.) This act shall not affect any police force maintained in respect of any railway, canal, or navigable river under private or local acts of Parliament. The rules and regulations made by the home secretary in pursuance of this act were laid before Parliament on the 22d February 1858.[2]

Scotch Police.

Police of Edinburgh.

In 1852 the amount of police force in the city of Edinburgh was 312, who were under the immediate control of a superintendent (appointed and removeable by the lord provost and sheriff of Mid-Lothian, with appeal to the lord advocate in case of difference), at a salary of L.350 a year, and under the general supervision of the police commission, composed of 32 members, annually elected by the different wards. The amount of police assessment, which includes the cleansing, lighting, and suppression of nuisance departments, as well as that of watching, was L.35,963, 19s. 5d.[3] In addition to the direct management of the city police, the superintendent is public prosecutor in police cases; on him, therefore, devolves the duty of preparing the charges which are to be determined by the judges of police. The subjoined tables show the number of charges brought before those judges, and the result, in each of the years 1854, 1855, and 1856:—

cottish re- ormatories nder Dun- p's Act, c.

The reformatory system was introduced into Scotland by the 17th and 18th Vict., c. 74 (Dunlop's Act), under the provisions of which fifteen reformatories have been certified; three others have been certified, both under it and under the 17th and 18th Vict., c. 86, and four under the provisions of the last-named statute only. The aggregate number of inmates on the 31st March 1858 was 813, of whom 537 were boys and 276 girls. The Glasgow industrial schools, certified on the 10th March 1855, contained, in March 1858, 129 children under detention (70 boys and 59 girls), and 70 other children attending school (42 boys and 28 girls). These schools are reported by the inspector as "conducted with great earnestness and ability," but exception is taken to the admixture of day scholars with the convicted children. Mr Turner also adds, "It is to be regretted that the provisions for compelling parents to contribute have remained hitherto a dead letter in Scotland; many of the inmates of the houses of refuge are the children of parents in the receipt of considerable wages. The schools certified under Mr Dunlop's act are in fact industrial feeding-schools of a superior description. Scarcely any of the children in them are committed under the act; the clause enabling the parochial boards to withdraw such children on giving security for their better protection having almost neutralized the direct operation of the statute altogether. But the indirect operation of the law appears to be considerable and very advantageous, large numbers of children coming voluntarily, or being sent by their parents,—from the knowledge that if found idling and begging in the streets, they can and will be sentenced to the school, and compelled to attend it. I think the value of these certified industrial schools in Scotland can scarcely be exaggerated."[2]

It would appear that the interval, short as it is, between the date of this report and that of the latest return of inmates in reformatories (31st March 1858) has brought with it considerable change in the relative numbers of detained and free scholars. The number of the former, detained under Dunlop's Act, is stated to be 287 (137 boys and 150 girls), besides 526 (400 boys and 126 girls) detained under 17 and 18 Vict., c. 86, as against 515 voluntary scholars (337 boys and 178 girls). The Glasgow "houses of refuge" alone contain 456 detained inmates, in addition to the 129 in the industrial schools.

Nuisances Removal Act (Scotland), 19 and 20 Vict., c. 103 (July 1856).

The police of public health in Scotland has been largely invigorated by the powers conferred on police commissions, town councils, and parochial boards by the act of the 19th and 20th Vict., c. 103: "An Act to make better provision for the Removal of Nuisances, Regulation of Lodging-Houses, and the Health of Towns in Scotland." This act consists of five distinct parts, the enactments of which are briefly as follows:—(1.) Power of entry, on reasonable belief of the existence of a nuisance, is granted to the local authority (whether commission, council, or board, as above mentioned, a committee thereof, or an inspector appointed thereby); and, on certificate, summary proceedings for abatement of such nuisance may be taken before any resident magistrate, and may be followed up by interdict, penalty, order of remedy at expense of the offending party, or other like procedure, requisite for such abatement. The term *nuisance* extends to the sale of unwholesome meat, and to the corruption of water; and, after due notice, daily and cumulative penalties may be inflicted. (2.) Orders in council may be issued, on fear of epidemic, endemic, or contagious diseases, for providing the boards of supervision of poor relief with proper medical officers (to be paid by Treasury), with power to make all due regulations for the removal or mitigation of such diseases; and, in case of the over-crowding of houses affected, may enforce against such houses the provisions hereafter mentioned for the regulation of common lodging-houses. (3.) The local authority shall cause a register to be kept of all common lodging-houses (such as lodge persons at a charge not exceeding threepence per night, whether paid nightly or weekly), and may refuse to register any such without a satisfactory certificate of character from three inhabitant rate-payers; may, with the approval of the secretary of state, make binding regulations for such houses; may cause additional water supply to be provided therein; may inspect such houses from time to time, and cause them to be properly cleansed and drained; may inflict penalties for infraction of the rules; and may, on a third conviction, refuse further license. (4.) Provision is also made for the enforcement of the act by the sheriff, in the event of neglect on the part of the local authority, or of nuisance occurring in which the local authority has any specific interest; penalties are inflicted for obstruction of the act; provision is made for the partition of costs and penalties in matters in which two or more owners are concerned. The police and constabulary are, within their respective jurisdictions, to assist in the execution of the act; and all rights of action at common law in respect of nuisances are preserved unimpaired. (5.) The 74th section of the "Burgh Police Act" (13 and 14 Vict., c. 33) is repealed, and in lieu thereof power is given to the commissioners to levy special sewer rates; powers are also given to borrow money for construction of sewers, and to repay the same by a sinking fund. The 213th section is also repealed, and power given to the commissioners to enforce the paving and flagging of streets by the owners of the property abutting thereon; and provision is made for the amendment of the "Burial Act" (Scotland), 18 and 19 Vict., c. 68, by defining several parishes, or parts of parishes, when comprehended within the limits of any burgh, as in the purview of such act, one united parish.

[2] *First Report of Inspector of Reformatory Schools, ut supra.*

IV. THE POLICE OF IRELAND.

Until the year 1814, the police of Ireland was in a state even more chaotic than that of England or of Scotland. The force that existed was capriciously administered, and not unfrequently grossly abused. Nor can it be matter of surprise that in days when political partizanship of a very emphatic sort was held to be no disqualification even for the judicial bench, the control of police, and the functions of the inferior magistracy, were often turned to factious purposes. The act of 1814 (54 Geo. III., c. 131) did not remedy these evils; but it led to improvements of detail, by the appointment of superintending magistrates, as well as to an increase of the constabulary force. Other acts followed of similar tendency, all of which were consolidated by the 6th Will. IV., c. 13. This act (passed in 1836) empowered the lord-lieutenant to appoint officers and constables in the several towns, baronies, and counties of Ireland, and in the proportions prescribed by the act; with an inspector-general at L.1500 per annum, and two deputy inspectors-general; and also to appoint fifty stipendiary magistrates at salaries ranging from L.400 to L.1000 per annum. The power already vested in the lord-lieutenant to appoint a special police force in any county or district proclaimed to be in a state of disturbance was to continue as before.

Constabulary act of 1836.

The force established under this act consisted of 42 inspectors and sub-inspectors, 465 chief and head constables, 7687 constables and sub-constables, 1 receiver, and 18 paymasters. Its total cost (in 1838) was, including the salaries of the stipendiary magistrates, L.380,268; of which sum, L.152,561 was paid by the counties and towns, and L.227,606 was borne by the Consolidated Fund.

Act of 1848, 11 and 12 Vict., c. 72.

The law of 1836 was amended in 1848 by the act of the 11th and 12th Vict., c. 72 ("An Act to amend the Acts relating to the Constabulary Force in Ireland, and to amend the provisions for the Payment of Special Constables"); and again by the 20th and 21st Vict., c. 17 ("An Act to amend the Act of the 11th and 12th years of Her Majesty, c. 72, so far as relates to the Distribution of the Constabulary Force in Ireland"), passed in July 1857. By this latter act the number of county inspectors was fixed at 35, that of sub-inspectors at 262, that of head constables at 375, and that of constables and sub-constables at 9591, for the whole of Ireland; making a total force, according to the statutory schedule, of 10,263 in 1857, as against 8194 in 1838; and a total cost of L.644,820,[1] as against L.380,268. Both sums include the salaries of stipendiary magistrates, the number of whom is now 72 (1 at L.646, 17 at L.500, 42 at L.400, and 12 at L.300 per annum).

Change in the incidence of Irish police expenditure made in 1846.

In the speech which Sir Robert Peel made on proposing the abolition of the corn laws (27th January 1846), after recommending that the whole expenses of criminal prosecutions, and of maintaining convicts (part of which were then borne by local rates), should be defrayed by the public treasury, he proceeded to say,—"At present you have a great police force in Ireland. The expense of a portion of that force is borne by the land in Ireland; the expense of the remainder is borne by the public treasury; and it certainly is a most anomalous system for one portion to be borne by the treasury and the other portion by the land. I believe that it will be an immense advantage to place the police force directly under the control of the executive; to prevent the possibility of all interference by local bodies; to make it as perfect a system as you can, excluding all power of local nomination or local interference, taking the whole control on the executive government; and in order that you may make that control complete, paying the expense out of the public treasury."

It is curious to notice in this famous speech so direct an attack on the two principles which have so largely and so long prevailed in our police arrangements,—namely, the joint support and the joint control of constabulary, as matters of common interest to the nation and to the locality. Nor will the special circumstances of Ireland suffice to bear out in its full breadth the policy thus enunciated. But no exception seems to have been taken by Irish members to any part of Sir Robert Peel's doctrine. The whole ordinary charge of the Irish constabulary force has been borne by the treasury, in addition to a grant in aid of the Dublin police, and the salaries of the Dublin police justices. The only charge now made to the counties and towns is the cost of the extra force employed in proclaimed counties and districts, that of men employed on railways and in boroughs, and that of revenue men, added to the constabulary force on the abolition of the revenue police in December 1857.

The effective strength and the pay of the constabulary stood thus on the 1st January 1858:—

I. *Constabulary Force of Ireland,—Strength and Pay, January* 1858.

[1] *Estimates of Civil Services—General Abstract of Grants*, &c. (26th March 1858), p. 3. The sum stated to be borne by the public in a subsequent return is L.651,406.

Irish Police.

The total cost of this force is stated, in the receiver's return of 15th July 1858 to be L.668,700 (including L.29,546 for the salaries of magistrates, and other sums for various allowances, for age, &c., and also the cost of clerks); and of this sum L.651,406, 10s. 10d. is stated to be borne by the public, and L.17,293, 11s. 2d. by counties, cities, and towns.[1]

ganiza- on of the ish con- abulary rce.

The Irish constabulary is organized on military principles, and is especially remarkable for the judicious plans by which Major-General Sir Duncan M'Gregor, the inspector-general, has combined competitive examination for cadetships with promotion from the ranks for good service and proved efficiency. Two-thirds of the vacant cadetships are filled up by the lord-lieutenant, and one-third by the inspector-general, who appoints alternately the son of an old constabulary officer and a head constable to his vacancies, thus filling every sixth vacancy from the ranks. The government candidates and the sons of officers are examined on the combined principle of nomination and competition in use in the civil service, four candidates being nominated for each vacancy, of whom the best is chosen. In the examination of head constables, every year's service, and every chevron or other mark of past merit, counts after a prescribed ratio, and unsuccessful head constables of a certain efficiency are permitted to undergo a second competitive examination. "The Irish constabulary force," it is stated, was already "remarkable for admitting no recruit who could not read and write and keep accounts, and for the entire trustworthiness of the men; so that they are sent by ones, twos, or threes to any place, however distant, where there is any duty to be performed, without an officer or non-commissioned officer being in charge of the party; and these competitive examinations have given an increased stimulus to the education of the force. Even the sub-constables in the remote country hamlets are employing schoolmasters in the evenings to instruct them in their barracks.[2]

Irish Police.

Dublin metropolitan police.

The metropolitan police of Dublin was established under the 6th and 7th Will. IV., c. 29, in 1836. It is controlled by two commissioners; is supported partly by police rate, fees, and penalties, and partly by the parliamentary grant already mentioned. Its effective strength and pay in July 1858 were respectively as follows:—

II. *Dublin Metropolitan Police,—Strength and Pay, July* 1858.

Rank.	No:	Pay.			
		L.	s.	L.	s.
Chief superintendent	1	286	10		
Superintendents	4	191	0 to	206	0
Chief inspector	1	160	0		
Inspectors	25	105	0 to	121	0
Acting inspectors	38	67	15		
Sergeants	66	54	0 to	65	0
Acting sergeants	100	50	0 to	62	0
First-class constables	238	48	0		
Second-class "	570	39	0 to	44	0
Third-class "	24	30	0		
Supernumeraries	20	18	5		
Total	1087				

The income and expenditure of the Dublin police establishment for the year 1856–7 were respectively as follows:—

III. *Dublin Metropolitan Police,—Income and Expenditure,* 1856–7.[3]

INCOME.	L.	s.	d.
Parliamentary grant	L.38,000	0	0
Police tax	21,715	0	2
Carriage duties, pawnbrokers' and publicans' licenses, &c.	15,334	2	0
Fines and penalties	2,000	0	0
Total	L.77,049	2	2

EXPENDITURE.	L.	s.	d.
Police courts	L.9,481	9	0
Salaries of commissioners, office establishment, &c.	9,218	2	9
Pay of the force	48,953	0	5
Pensions	3,652	6	1
Rent, taxes, repairs, and other incidental expenses,	5,721	18	7
Total	L.77,026	16	10
Excess of income over expenditure	22	5	4
	L.77,049	2	2

The Dublin police district is nearly 40 square miles in extent, and contains nearly 400,000 inhabitants. The subjoined table shows the number of persons taken into custody, and the results of the hearing of their cases before the magistrates, in each of the years 1854, 1855, and 1856:—

IV. *Dublin Metropolitan Police,—Apprehensions and their Results,* 1854–56.

Year.	Total Number of Apprehensions.	Summary Procedure.		Committed for Trial.	Results of Committal.		
		Discharged.	Convicted.		No Bill, &c.	Convicted.	Acquitted.
1854	43,108	11,810	30,066	1232	184	741	307
1855	35,634	10,667	24,188	779	114	478	187
1856	38,876	14,506	23,692	678	115	413	150
Total of 3 years	117,618	36,983	77,946	2689	413	1632	644

Both committals and convictions, it will be seen, show a decrease in each year as compared with the preceding year. This decrease, too, continued to maintain itself in 1857. But in the last-named year it was characterized by a special feature, sufficiently exceptional to claim a word of notice, although bearing on the sexual proportions of crime —a point of detail which we have excluded from these tables in order to confine them within narrow limits. During the three years 1854–56, the decrease in *male* crime throughout Ireland was relatively greater than that in female crime. In 1857, on the contrary, the decrease in *female* crime was ten times as great as that in male crime. The classification of the offences comprised in the preceding table is as follows:—

Reformatory Schools (Ireland) Act, 21 and 22 Vict., c. 103.

An act of the 21st and 22d Vict., c. 103, entitled "An Act to Promote and Regulate Reformatory Schools for Juvenile Offenders in Ireland," which became law on the 2d August 1858, makes provision for the training of juvenile criminals into habits of honest industry, similar to those which had been for some years in operation in England and Scotland. Grand juries and town councils are empowered to make grants of money in aid of such reformatory schools, duly certified under the act, if they shall think fit; the powers of justices to commit youthful offenders, for periods not more than five years nor less than one year, resemble those accorded by the English law,—"Provided that no such offender shall be liable or directed to be sent to any such reformatory, except to some one reformatory under the exclusive management of persons of the same religious persuasion as that professed by the parents or guardians of such juvenile offenders; and in all cases in which the religion of the parents or guardians is unknown, the said offender shall be considered as belonging to that religious persuasion in which he or she shall appear to have been baptized, or of which he or she shall profess to be a follower." Provisions are also made for the enforcement of due contributions by parents, if of sufficient ability, towards the maintenance of such offenders in the reformatory school.

Concluding observations.

Many years must pass before the full value of reformatory schools can broadly evince itself in their results. But it is already beyond question that no other measures of police have struck so directly at the roots of crime; nor is any recent legislation more pregnant with encouragement to solitary thinkers and obscure workers in the field of social reform. During the century which has elapsed since Fielding aroused public attention to the growing number of criminals who at that time were "once in six weeks carried to slaughter," and to the "dreadful consideration that, with proper care and proper regulations, much the greater part of these wretches might have been made not only happy in themselves, but very useful members of the society which they now so greatly dishonour in the sight of all Christendom," the best portions of many lives have been devoted to the discovery and application of the wisest methods for the abatement of that scandal. Every step in the process has been one of difficulty and struggle, but the good work has been urged onward in the face, not of opposition alone, but sometimes of obloquy. Efforts for the recovery of the criminal have been represented as injuries to the honest. The labours of John Howard have been decried as the expression of morbid sensibilities. And there was something in the doctrine, when clothed in brilliant rhetoric, which looked to some minds like profundity; but the workers worked on.

As respects the ordinary duties of police within the United Kingdom, recent legislation seems to have provided an effective machinery, the further improvement of which is but matter of experience and detail. There are still towns so inadequately provided as to be a source of danger to their neighbours; but the County Constabulary Act will in time provide a remedy. Meanwhile the union of local management with government inspection and publicity insures the general combination of efficiency and economy. But as regards the direct repression of crime there is yet a serious deficiency,—the absence of any adequate register of offences, irrespectively of their detection or pursuit.

Register of crimes.

Registration of this kind presents many difficulties. It ought not to be under the entire control of police functionaries. It cannot be obtained independently of them. It will require at every step the scrutiny of men familiar with the tricks and subterfuges of the "dangerous classes" of society. As it is, police returns include crimes that were never committed; although, of course, their most frequent error is of an opposite kind. Until these difficulties have been overcome, and a registration of offences presenting a reasonable approximation to truth obtained, no just standard will exist by which to measure police efficiency.

reatment released iminals.

The supervision of released criminals is another knotty point to which public attention has been repeatedly aroused, and especially by the recorder of Birmingham, Mr M. D. Hill, in his charges to grand juries, and in other ways. "I propose," said Mr Hill, on one of these occasions, "that every person who has been convicted of a felony, or of a misdemeanour implying fraud (as obtaining goods under false pretences, knowingly passing base coin, and the like), shall be liable to be dealt with as follows:—If after the expiration of his imprisonment under his conviction, he shall be brought before a magistrate *charged with still persevering in crime*, it shall be the duty of the magistrate, if the witnesses, *by evidence of general conduct,* satisfy his mind that the charge is established, to call on the prisoner to show that he enjoys the means of honest subsistence, either from his property, his labour, the kindness of his friends, the bounty of the charitable, or from his parish. Should he succeed in adducing this proof, he is to be discharged. Should no such proof be forthcoming, he is next to be called upon to give bail for his good behaviour. Supposing him to answer this demand, he is to be still entitled to his discharge. But in the event of his failure, he is then to be held to bail on his own recognisances, and his case to be sent to a jury at the assizes or sessions, when, if a verdict pass against him, he is to be imprisoned for a term to be fixed by the law, but capable of diminution by the judge before whom he is tried." Public opinion has not endorsed this proposal; but the question is a pending one. Mr Hill has, we think, refuted some objections that have been urged against his plan. But he has not met the case of the men whom it would discharge for having shown that they *are* gaining a livelihood by labour, the continuance of which the process might make impossible. Nor does it quite appear that conclusive evidence of the charge would usually involve less vigilance and skill than might suffice to prove specific offences. The problem, however, is a weighty one, and every effort to grapple with it is a public service.

Recent inquiries into the conduct of English and Irish police in affrays.

It is almost self-evident that, with every improvement in the mechanism of our police, thorough control over it becomes more and more important. Within a brief period there have been two inquiries into the conduct of constabulary on memorable occasions,—the one, metropolitan, on the affray in Hyde Park, when Sabbath legislation was in question (or in pretext); the other at Belfast, brought about by faction fights. On the whole, both inquiries acquitted the force impugned of the worst charges brought against it, and, full account taken of its difficult duties, tended to its credit. Sir George Grey's circular on the former occasion dealt very fairly with the matter, save, as we think, (after no careless examination of the bulky volume of evidence), that he passed too lightly over that besetting sin of so many police functionaries, the tendency to treat accused persons as guilty persons. On that point the evidence substantiated most reprehensible practices. There is nothing in the administration of police which it behoves the public to watch more jealously.

Another tendency, which is far more visible in continental countries than in our own, may nevertheless deserve a remark; we mean the tendency to carry interference into trivialities. In one of Goethe's conversations with Eckermann there is a passage in which he strikingly depicts the cowed children whom he saw not unfrequently from his window "in our own dear Weimar," flying before the terrible police. "Now," he added, "when the spring sun tempts them from the houses, and they would like to play with their companions before the door, I see them always constrained, as if they were not safe, and feared the approach of some despot of the police. Not a boy may crack a whip, or sing, or shout; the police is immediately at hand to forbid it." Many of us have seen similar things. But that is an evil which in this country (other influences co-operating) will rapidly disappear, as the men themselves become better educated and better trained in their duties. To ensure a police at once efficient and discreet, careful selection, adequate pay, and honourable recognition of meritorious service are the obvious requisites. (E. E.)

POLICY. See Insurance.

POLIDORO. See Caravaggio, *Polidoro Da*.

POLIGNANO, a town of Naples, in the province of Bari, stands on a steep cliff hollowed out by the sea into caverns, and commanding a wide view over a rich and well-cultivated region, 20 miles S.E. of Bari. It contains several churches, an abbey, and a convent. Some coins and other remains have been found in the vicinity. Pop. 5000.

POLIGNY, a town of France, capital of an arrondissement in the department of Jura, on the edge of an extensive plain at the foot of a branch of the Jura Mountains, 18 miles N.E. of Lons-le-Saulnier, and 49 N.W. of Geneva. It was formerly walled, and has still the ruins of an old citadel standing on an eminence. The principal streets, four in number, are regular, well-built, and adorned with several fine fountains. There are no remarkable public buildings, but the town-hall, a college, and manufactories of pottery, saltpetre, leather, &c.; as well as dye-houses, saw-mills, and iron-works. Marble and alabaster are quarried in the neighbourhood. Pop. (1856) 5208.

POLILLO, a small island of the Philippine group, lying to the E. of Luzon, N. Lat. 15. 5., E. Long. 122. 6. It is 30 miles in length, and about 20 in breadth. The soil is very fertile; and a lofty hill, called Malolo, rises in the centre. It has several good harbours, and especially one of the same name as the island on the S.W. coast.

POLISTINA, or Polistena, a town of Naples, in the province of Calabria Ultra I, on an elevated and fertile plain, 13 miles E.N.E. of Palmi. The old village of this name, which stood on the sides of two hills, was totally destroyed by an earthquake in 1783, being entirely thrown into a ravine then formed. Since that catastrophe the present town has been built. Pop. 6000.

POLITIANO, Angelo, was born at Monte Pulciano in Tuscany in the year 1454. He studied the Greek language, of which he became a complete master, under Andronicus of Thessalonica. He was greatly favoured by Lorenzo de' Medici in his education, and he is said to have written verses both in Greek and in Latin when he was not more than twelve years of age. He also studied the Platonic philosophy under Marsilius Ficinus, and that of Aristotle under Argyropylus. Politiano was one of the most learned and polite writers of his time. The first work which gained him a reputation was a poem on the tournament of Julian de' Medici. The account he wrote, some time afterwards, of the conspiracy of the Pazzi, was also very much esteemed. Erasmus and the two Scaligers mention him in terms of the highest praise. He composed many other pieces which merit approbation; and had he lived longer, he would have enriched the republic of letters with many excellent works. He died at the age of forty. The first edition of his works was that of Aldus, Venice, 1498; and many others followed till 1820, when they were inserted in the *Bibliotheca Poetica Italiana*.

POLITICAL ECONOMY.

Political Economy.

The subordinate parts of the science of political economy have been treated in separate articles of this work, with the fulness which their importance seemed to require. The present article, therefore, will be principally confined to an attempt to define the objects and limits of the science—to trace its progress—to exhibit and establish the fundamental principles on which it is founded—and to point out the relation and dependence of its different parts. In doing this, we shall have occasion to examine some of the more prominent theories advanced in this field of inquiry; our object being, not merely to lay before the reader what we conceive to be a true theory of the science, but also to present him with as full an exposition as our limits will allow of the doctrines advocated by the more celebrated of its professors.

PART I.

DEFINITION AND HISTORY.

Definition of the Science.—Causes of its being neglected in Greece and Rome, and in the Middle Ages.—Species of Evidence on which its Conclusions are founded.—Rise of the Science in Modern Europe.—Mercantile System.—Progress of Commercial Philosophy in England in the Seventeenth and Eighteenth Centuries.—System of Quesnay and the French Economists.—Publication of the "Wealth of Nations."—Distinction between Politics and Statistics, and Political Economy.

Definition of the science.

Political economy[1] is *the science of the laws which regulate the production, distribution, and consumption of the products and services necessary, useful, or agreeable to man, which it requires some portion of voluntary labour to produce, procure, or preserve.*

This definition has been framed so as to exclude all reference to whatever exists independently of man, and may be obtained in unlimited quantities without any laborious exertion. Had such been the case with the various articles required to satisfy our wants and desires, political economy would not have existed. It is the most practical of sciences, for it is exclusively conversant with the application, the objects, and the results of art and industry. It may indeed be said to be the science of values, inasmuch as those things only which may be exchanged or bartered for other things that are either wholly or in part produced by means of voluntary exertion or labour come within the scope of its inquiries. An article may be possessed of the highest degree of *utility*, or, as it is sometimes termed, of intrinsic worth, and yet be wholly destitute of value in exchange. Without utility of some sort or other, nothing can ever become an object of desire or demand. But however necessary an article may be to our comfort, or even existence, and however much it may be in demand, still, if it be a spontaneous production of nature, if it exist independently of human agency, and if every individual have an indefinite command over it, it cannot become the subject of an exchange, or afford any basis for the reasonings of the economist. Though food and clothes are not more useful than atmospheric air, they possess that value of which it is destitute. The reason is obvious. They are not, like air, gratuitous products, which may be had at all times without any exertion; they are obtainable only by labour. And as none will voluntarily sacrifice the fruits of their industry without an equivalent, they are truly said to possess exchangeable worth.

Definition.

Distinction between value in exchange and utility.

The word *value* is, we are aware, very often employed to express the utility as well as the exchangeable worth of articles; but as these qualities have nothing in common, this double employment had better be avoided. It is obvious, for example, that the utility of bread and water, or their capacity to appease hunger and quench thirst, is something fundamentally different from their value or capacity to exchange for or buy other things. Adam Smith perceived this difference, and was alive to the importance of carefully distinguishing between the utility, or, as he expressed it, the "value in use," of commodities, and their value in exchange. But he did not always keep this distinction in view, and it has been frequently lost sight of by later writers. There can, indeed, be no doubt that the confounding of these opposite qualities has been a principal cause of the confusion and obscurity in which many branches of the science, not in themselves difficult, are still involved. When it is said that water is highly valuable, it is meant that, being indispensable to existence, it has a high degree of utility, or of value in use; for, being usually obtainable in large quantities with little labour or exertion, it has in most places a very low value in exchange. But when it is said that gold is highly valuable, a totally different meaning is attached to the phrase. Gold is of comparatively small utility; but as it requires a great deal of labour and expense to bring limited quantities of it to market, it has a high value in exchange, and is readily accepted as an equivalent for large quantities of most other articles. To confound qualities which are so very different must evidently lead to erroneous conclusions. And therefore, to avoid all chance of error from mistaking the sense of so important a word as *value*, we shall not use it except to signify exchangeable worth, or value in exchange; and shall employ the word *utility* to express the power or fitness of an article to satisfy our wants and desires.

Were utility and value identical, or were they regulated by the same laws, it would follow, that whatever increased the utility of an article would also increase its value, and *vice versa*. But the fact is completely the reverse. A deficient harvest adds nothing to the utility—that is, to the nutritive power—of bread; while, by increasing its value and price, it adds to the privations of the great bulk of the consumers, and especially to those of the lower and poorer and most numerous classes. And so in every case. A rise of value or price is always publicly injurious; and conversely. Were the manufacture of hats improved so that they might be sold for half their present price, everybody would gain by the change. Those by whom they have been worn would save half their outlay upon them, while they would be brought within the reach of others who may hitherto have been too poor to become their purchasers. The discovery of the rules or principles by the application of which the value of commodities may be reduced to the lowest limits, is a principal object of this science. For, the more their value is reduced, the more obtainable they become, and the greater, consequently, is the amount of necessaries and conveniences at the disposal of individuals.

Definition of the term *wealth.*

Political economy has frequently been defined to be "the science which treats of the production, distribution, and con-

---

[1] *Economy,* from οικος, *a house* or *family,* and νομος, *a law—the government of a family.* Hence political economy may be said to be to the state what domestic economy is to a family.

Definition.

sumption of *wealth;*" and if by wealth were meant those products which possess exchangeable value, and are necessary, useful, or agreeable, the definition would be one of the least exceptionable. But those by whom it has been adopted have given to wealth a different and in general much too extensive a meaning. They have sometimes, for example, considered it as synonymous with "*all that man desires as useful and agreeable.*" But if political economy were to embrace a discussion of the production and distribution of whatever is useful and agreeable, it would include within itself every other science; and the best Encyclopædia would be the best treatise on political economy. Good health is the greatest of boons, and therefore, on this hypothesis, the science of wealth should comprise the science of medicine; civil and religious liberty are highly desirable, and therefore the science of wealth should comprise the science of politics, and so on. Such definitions are obviously worse than useless. They generate confused and erroneous notions respecting the objects and limits of the science, and prevent the student acquiring a distinct idea of the nature of the inquiries in which he is engaged.

Malthus defined wealth to consist of "those material objects which are necessary, useful, and agreeable to man." (*Principles of Political Economy*, p. 28.) But waiving the objections that may perhaps be made to the introduction of the word "material," it is too comprehensive to be of use. Atmospheric air and the heat of the sun are both material products, and are highly useful and agreeable. But their independent existence and incapacity of appropriation exclude them, as already seen, from the investigations of this science.

Adam Smith has not explicitly stated what was the meaning which he attached to the term wealth. Probably, indeed, his ideas on the subject were not very precise; but he most commonly describes it as "the annual produce of land and labour." It has, however, been objected to this definition, that it refers to the sources of wealth before it is known what wealth is, and that it includes the useless products of the earth, as well as those which are appropriated and enjoyed by man.

The definition we have given is not open to any of these objections. By confining the science to a discussion of the laws which regulate "the production, distribution, and consumption of those products and services which have exchangeable value, and are necessary, useful, or agreeable," we give it a distinct and definite object. When thus properly restricted, the researches of the economist occupy a field which is exclusively his own. He runs no risk of wasting his time in inquiries which belong to other sciences, or in unprofitable investigations respecting the production and consumption of articles which cannot be appropriated, and exist independently of human agency.

Capacity of appropriation is indispensable to constitute wealth. And we shall invariably employ this term to distinguish those products which are obtainable only by the intervention of human labour, and which may in consequence be appropriated and consumed exclusively by their owners. A man is not said to be wealthy because he has an indefinite command over atmospheric air; for that being a privilege which he enjoys in common with every one else, it forms no ground of distinction. But he is said to be wealthy according to the degree in which he can afford to command those necessaries, conveniences, and luxuries which are not the gifts of nature, but the produce of industry. It must, however, be carefully observed, that though value and wealth be constantly conjoined, they are not identical, but are as widely different as utility and value. Our command of the necessaries and gratifications of which wealth consists will evidently be greater when their value declines than when it increases. It is a law of this science that *wealth and value vary inversely*—the one increasing as the other diminishes, and diminishing as the other increases. Wealth is greatest where the facility of production is greatest, and value is greatest under the opposite circumstances, or where the difficulty of production is greatest.

Definition.

Importance of the science.

Besides being exclusively conversant with that class of phenomena which the exertion of industry exhibits, the object of this science is to ascertain the means by which the latter may be rendered most productive of the necessaries, luxuries, and enjoyments which form wealth; the laws which determine the distribution of wealth among the different classes into which society is divided; and how it may be most profitably consumed. To enter into lengthened arguments to prove the importance of a science having such objects in view would be worse than useless. The consumption of wealth is indispensable to existence; but the eternal law of Providence has decreed that it can only be procured through the intervention of industry—that man must earn his bread "in the sweat of his face." This twofold necessity renders the production of wealth a constant and principal object of the exertions of the vast majority of the human race. It has subdued the aversion of man from labour, given activity to indolence, and armed the patient hand of industry with zeal to undertake, and perseverance to overcome, the most difficult and disagreeable tasks.

When pursued with proper diligence, these efforts seldom fail to attain the end in view. And while they furnish the bulk of society with ample supplies of the articles required for their comfortable subsistence, they afford time for the cultivation of those speculative inquiries and elegant tastes which elevate and adorn civilized man. To use the words of Dr Barrow,—"Wealth is that which generally men of all things are wont to affect, and covet with most ardent desire, as the great storehouse of their needs and conveniences, the sure bulwark of their state and dignity, the universal instrument of compassing their designs and pleasures; and most evident it is, that in the natural course of things industry is the way to acquire it, to secure it, to improve and enlarge it; the which course, pursued innocently and modestly God will be so far from obstructing, that He will further and bless it; for that indeed it would be a flaw in Providence if honest industry, using the means it affordeth, should fail of procuring a competency."[1]

But when the acquisition of wealth makes a part of the order of Providence, and is indispensable not merely to the supply of our necessary wants, but to our progress in intelligence and refinement, can we doubt the importance of the science which teaches the modes by which its acquisition may be facilitated, and the greatest amount of wealth obtained with the least difficulty? There are none to whom a knowledge of political economy can be considered as extrinsic or superfluous. There are some, doubtless, to whom it may be of more advantage than to others; but it is of paramount consequence to all. The prosperity of individuals and nations does not depend nearly so much on salubrity of climate or fertility of soil, as on their ability to apply labour with perseverance, skill, and judgment. Industry can balance almost every other deficiency. It can render regions, naturally inhospitable and unproductive, the comfortable abodes of an intelligent and refined, a crowded and wealthy population. But where it is wanting, the choicest gifts of nature are of no value; and countries possessed of the greatest capabilities of improvement with difficulty furnish a miserable subsistence to the scanty population of hordes distinguished only by their barbarism and wretchedness.

---

[1] See the first of Dr Barrow's eloquent and admirable Sermons on Industry.

Such being the case, it may well excite astonishment that the study of political economy was not early considered as forming a principal part in a comprehensive system of education. Two circumstances, to which we shall now briefly advert, seem to have been principally instrumental in occasioning its neglect,—the institution of domestic slavery in the ancient world, and the darkness of the period when the plan of education in the universities of modern Europe was first organized.

Causes of the neglect of this science in antiquity and the middle ages.

The citizens of Greece and Rome considered it degrading to employ themselves in those occupations which form the principal business of the inhabitants of modern Europe. In some of the Grecian states they were prohibited from engaging in manufacturing or commercial industry; and in Athens and Rome, where this prohibition did not exist, these employments were regarded as mean, mercenary, and unworthy of freemen, and were carried on either by slaves, or the very dregs of the people.[1] Agriculture was treated with more respect. Some of the most distinguished characters in the earlier ages of Roman history had been actively engaged in rural affairs. But notwithstanding their example, in the later ages of the republic, and under the emperors, the cultivation of the soil was usually carried on by slaves belonging to the landlords, and employed on their account. The mass of Roman citizens were mostly engaged in the military service,[2] or derived a precarious and dependent subsistence from the supplies of corn furnished by the conquered provinces. The relations subsisting in modern Europe between landlords and tenants, and masters and servants, being thus in great measure unknown, the ancients were comparative strangers to those interesting questions growing out of the rise and fall of rents and wages which form so important a branch of this science. The philosophy of the ancient world was also extremely unfavourable to its cultivation. The luxurious or more refined mode of living of the rich was regarded by the ancient moralists as an evil of the first magnitude. They considered it as subversive of those warlike virtues which were the principal objects of their admiration; and they denounced the passion for accumulation as being fraught with the most injurious consequences. Political economy could not become an object of attention to men imbued with such prejudices; nor could it be studied by those who held the objects about which it is conversant in contempt, and spurned the labour by which they are produced.

At the establishment of our universities, the clergy being almost the exclusive possessors of the little knowledge then in existence, their peculiar feelings and pursuits naturally exercised a marked influence over the plans of education they were employed to frame. Grammar, rhetoric, logic, school divinity, and civil law comprised the whole course of study. To have appointed professors to explain the principles of commerce, and the means by which labour might be rendered most efficient, would have been considered as alike superfluous and degrading to the dignity of science. The prejudices against commerce, manufactures, and luxury, generated in antiquity, had a powerful influence in the middle ages. None had then any clear ideas of the true sources of wealth, happiness, and prosperity. The intercourse between different countries was extremely limited, and was confined rather to marauding excursions, and a piratical scramble for the precious metals, than to a commerce founded on the gratification of real or reciprocal wants.

These circumstances sufficiently account for the slow progress of this science, and the little attention paid to it, down to a very recent date. And since it became an object of more general attention and liberal inquiry, the opposition between the theories and opinions of the most eminent of its professors—an inevitable result of its recent cultivation—has proved unfavourable to its progress, and generated a disposition to distrust its best established conclusions. This, however, is an extremely ill-founded prejudice; and notwithstanding the diversity of the theories that have been formed to explain its various phenomena, it admits of as much certainty in its conclusions as any science not dependent on mere relation. A brief exposition of the principles on which it is founded, and of the mode in which its investigations should be conducted, will evince the correctness of this statement.

Principles of the science. Nature of the evidence on which its conclusions are founded.

Political economy is not a science of speculation, but of fact and experiment. The principles on which the production and accumulation of wealth, and the progress of civilization depend, are not the offspring of legislative enactments. Man's existence depends on his exerting himself to produce wealth; and the desire by which he is actuated to rise in the world and improve his condition impels him to save and accumulate. The principles which form the basis of this science make, therefore, a part of the constitution of man and of the physical world; and their operations, like those of the mechanical principles, may be traced by the aid of observation and analysis. There is, however, a material distinction between the physical and the moral and political sciences. The conclusions of the former apply in *every* case, while those of the latter apply only in the *majority* of cases; and the theorist must satisfy himself with framing his rules so as to explain their operation in the greater number of instances, leaving it to the sagacity of the observer to modify them so as to suit particular cases. Thus it is a principle admitted alike in morals and political economy, that by far the greater number of individuals have a much clearer view of what is conducive to their own interests than it is possible for any other man, or select number of men, to have; and that, therefore, it is sound policy to allow them to follow the bent of their inclination, and to engage in such branches of industry as they think proper. This is the general theorem; and it is one which is established on the most comprehensive experience. It is not, however, universally applicable, like the laws which regulate the motions of the planetary system. It will hold good in nine out of ten instances, but the tenth may be an exception. But it is not required of the economist that his theories should square with the peculiar bias of a particular person. His conclusions are drawn from contemplating the principles which are found to determine the condition of mankind, as presented on the large scale of nations and empires. His business is with man in the aggregate, with states, and not with families, with the passions and propensities which actuate the great bulk of the human race, and not with those which are occasionally found to influence a solitary individual.

---

[1] The force of the prejudices on this head may be learned from the following quotations:—"Illiberales autem et sordidi," Cicero says, "questus mercenariorum, omniumque quorum operæ, non quorum artes emuntur. Est enim illis ipsa merces auctoramentum servitutis. Sordidi etiam putandi, qui mercantur a mercatoribus quod statim vendant, *nihil enim proficiunt, nisi admodum mentiantur!* Opificesque omnes in sordida arte versantur, *nec enim quidquam ingenuum potest habere officina*. . . Mercatura autem, si tenuis est, sordida putanda est; sin autem magna et copiosa, multa undique apportans, multisque sine vanitate impertiens, non est admodum vituperanda." (*De Officiis*, lib. i., sect. 42.) "Vulgaris opificum, quæ manu constant, et ad instruendam vitam occupatæ sunt; in quibus nulla decoris, nulla honesti simulatio est." (Senecæ *Epistolæ*, ep. 89.) A hundred similar quotations might be produced, but the one from Cicero is sufficient to establish the accuracy of what has been advanced. The strength of the prejudice against commerce and the arts is proved by its exerting so powerful an influence over so cultivated a mind. For a further discussion of the opinions of the Romans on this subject see the *Dissertazione del Commercio de Romani* of Mengotti, which received a prize from the Academy of Paris in 1787, and the *Memoria Apolegetica del Commercio de Romani* of Torres, published at Venice in 1788.

[2] "Rei militaris virtus præstat cæteris omnibus; hæc populo Romano, hæc huic urbi æternam gloriam peperit." (Cicero *pro Murena*.)

This distinction should be kept constantly in view. Nothing is more common than to hear it objected to some of the best established truths in politics and political economy, that they are at variance with certain facts, and that, therefore, they should be rejected. But these objections very often originate in an entire misapprehension of the subject. It would be easy to produce a thousand instances of individuals who have been enriched by monopolies and restrictions, and even by robbery and plunder; though it would be rather rash thence to conclude that society may be enriched by such means! This, however, is the single consideration to which the economist has to attend. And until it can be shown that monopolies and restrictions are not destructive of national wealth, and that what is gained by the monopolist is not lost by the public, he is bound to regard them as injurious. To arrive at a well-founded conclusion in this science, it is not enough to observe results in particular cases, or as they affect a few individuals; we must further inquire whether these results be constant and universally applicable; whether the same circumstances which have given rise to them in one instance, would in every instance, and in every state of society, be productive of the same or similar results. A theory which is inconsistent with an uniform and constant fact must be erroneous. But the observance of a particular result at variance with customary experience, and when we may not have the means of discriminating the circumstances attending it, should not make us hastily modify or reject a principle which accounts satisfactorily for the greater number of appearances.

The example of the few arbitrary princes, distinguished by their equity, humanity, and generosity, is not enough to overthrow the principle which teaches that it is of the essence of irresponsible power to debauch and vitiate its possessors, to render them haughty, cruel, and suspicious: nor is the example of those who, attentive only to present enjoyment, and careless of the future, lavish their fortunes in boisterous dissipation or vain expense, sufficient to invalidate the conclusion, that the passion for accumulation is stronger and more powerful than the passion for expense. Had this not been the case, mankind could hardly have emerged from the condition of savages. The stupendous improvements which have been made in different ages and nations, the forests that have been cut down, the marshes and lakes that have been drained and cultivated, the harbours, roads, and bridges that have been constructed, the cities and edifices that have been raised, are *all* the fruit of a saving of income, and establish, in despite of thousands of instances of prodigality, the ascendancy and superior force of the accumulating principle.

The want of attention to these considerations has occasioned much of the error and misapprehension with which this science has been infected. The false theories and opinions which have successively appeared, though destitute of any real foundation, have mostly been supported by an appeal to facts. But a knowledge of facts, without a knowledge of their mutual relation, without being able to show why the one is a cause and the other an effect, is, as Say has observed, no better than the indigested erudition of an Almanac-maker, and affords no means of judging of the truth or falsehood of a general principle.

But though we are not to reject a received principle because of the apparent opposition of a few results with the circumstances of which we are unacquainted, we should have no confidence in its solidity, unless it be deduced from a comprehensive and careful induction. He who would arrive at a true knowledge of the laws regulating the production, distribution, and consumption of wealth, must draw his materials from a very wide surface, and study man under very different aspects. He should have recourse to the history of society, arts, commerce, and civilization; to the works of philosophers and travellers; to everything, in short, that may throw light on the causes which accelerate or retard the progress of civilization. He should observe the changes which have taken place in the fortunes and condition of the human race in different regions and ages; he should trace the rise, progress, and decline of industry; and, above all, he should carefully discriminate the effects of political measures, and the various circumstances wherein advancing and declining societies differ from each other. Such investigations, by disclosing the real causes of national opulence and refinement, and of poverty and degradation, furnish the means of satisfactorily solving almost all the important problems in the science of wealth, and of devising a scheme of administration calculated to insure the continued improvement of nations.

It should be kept in mind, that it is no part of the business of the economist to inquire into the means by which individual fortunes may be increased or diminished, except to ascertain their general operation and effect. The *public interests* should always form the exclusive objects of his attention. He is not to frame systems, and devise schemes, for increasing the wealth and enjoyments of particular classes; but to apply himself to discover the sources of national wealth and universal prosperity, and the means by which they may be best secured and rendered most productive.

Those who reflect on the variety and extent of knowledge required for the construction of a sound theory of political economy will cease to feel any surprise at the errors into which economists have been betrayed, or at the discrepancy of the opinions still entertained on some important points. This science is of very recent origin. Though various treatises of considerable merit had previously appeared on some of its separate parts, it was not treated as a whole, or in a systematic manner, until about the middle of last century. This circumstance is of itself enough to account for the number of erroneous theories that have since appeared. Instead of deducing their general conclusions from a comparison of particular facts, and a careful examination of the phenomena attending the operation of different principles, and of the same principles under different circumstances, the first cultivators of almost every branch of science begin by framing their hypotheses on a very narrow and insecure basis. Nor is it really in their power to go to work differently. Observations are scarcely ever made or particulars noted for their own sakes. It is not till they begin to be in request as furnishing the only test by which to ascertain the truth of some popular theory, that they are made in sufficient numbers and with sufficient accuracy. The *effectual demand* of the theorist occasions, in the peculiar phraseology of this science, the production of the facts or raw materials he is afterwards to work into a system. The history of political economy exemplifies the truth of this remark. Being, as already observed, entirely unknown to the ancients, and but little attended to by our ancestors down to a comparatively late period, those circumstances which would have enabled us to judge with the greatest precision of the wealth and civilization of the more celebrated states of antiquity, and of Europe during the middle ages, have either been thought unworthy of notice by the historian, or have been very imperfectly and carelessly detailed. Those, therefore, who first began to trace the principles of the science had but a comparatively scanty experience on which to build their conclusions. Nor did they even avail themselves of the few historical facts with which they might easily have become acquainted, but confined their attention almost exclusively to those which happened to fall within the sphere of their own observation.

Mercantile system.

Agreeably to what has now been stated, we find that the theories advanced by the early economical writers were formed on the most contracted basis, and were only fitted to explain a few obvious and striking phenomena. The *mercantile theory*, for example, was entirely bottomed on the popular and prevalent opinions respecting money. The precious metals having been long used, both as standards by which to ascertain the values of different commodities, and as the equivalents for which they were most frequently exchanged, acquired a fictitious importance in the estimation of persons of the greatest discernment, as well as of the vulgar. The obvious fact, that all buying and selling is really nothing more than the bartering of one commodity for another—of a certain quantity of corn or wool, for example, for a certain quantity of gold or silver, and *vice versa*, was entirely overlooked. The attention was gradually transferred from the money's worth to the money itself; and the wealth of individuals and of states came to be measured by the quantities of the precious metals actually in their possession, and not by the abundance and value of the disposable products with which they could afford to purchase these metals. On this flimsy and fallacious hypothesis are founded the theories of almost every writer on economical subjects antecedent to the appearance of the works of Child, North, and Locke in England, and of Gournay and Quesnay in France. And, which is of infinitely greater moment, it is on this same hypothesis that the great powers of Europe proceeded to regulate their intercourse with each other. Their grand object was to monopolize the largest possible supplies of gold and silver, not to facilitate the production of necessaries, comforts, and luxuries. And as gold and silver could not be obtained in countries destitute of mines, except in exchange for exported commodities, various schemes were set on foot for encouraging exportation, and for preventing the importation of most products other than the precious metals. In consequence, an excess of exports over imports was long considered as the best possible proof that a country was advancing in the accumulation of wealth: For it was believed that this excess could not be balanced otherwise than by an equivalent importation of gold or silver, or of the only real wealth which it was supposed a country could possess.

These principles and conclusions, though entirely false and erroneous, afford a tolerable explanation of a few very obvious phenomena, and are in perfect unison with the popular prejudices on the subject. It was natural, therefore, that they should be espoused by the merchants or practical men, who were the earliest writers on commerce. They did not consider it necessary to subject the principles they assumed to any refined analysis or examination. But, reckoning them as sufficiently established by the common consent of mankind, they applied themselves to the discussion of the practical measures calculated to give them the greatest efficacy.

Balance of trade.

"Although a kingdom," says one of the earliest and ablest writers in defence of the mercantile system, "may be enriched by gifts received, or by purchase taken, from some other nations, yet these are things uncertain, and of small consideration when they happen. The ordinary means, therefore, to increase our wealth and treasure is by foreign trade, wherein we must ever observe this rule,—to sell more to strangers yearly than we consume of theirs in value. For suppose that when this kingdom is plentifully served with cloth, lead, tin, iron, fish, and other native commodities, we do yearly export the overplus to foreign countries to the value of L.2,200,000, by which means we are enabled, beyond the seas, to buy and bring in foreign wares for our use and consumption to the value of L.2,000,000. By this order duly kept in our trading, we may rest assured that the kingdom shall be enriched yearly L.200,000, which must be brought to us as so much treasure; because that part of our stock which is not returned to us in wares must necessarily be brought home in treasure." (Mun's *Treasure by Foreign Trade*, orig. ed., p. 11.)

The gain on our foreign commerce is here supposed to consist exclusively of the gold and silver which, it is taken for granted, must be brought home in payment of the excess of exported commodities. Mun lays no stress on the circumstance of foreign commerce enabling countries to obtain an infinite variety of useful and agreeable products, of which, but for it, they would be wholly deprived, while it supplies them with a great many more at comparatively low prices. We are desired to consider the innumerable additions which are thus made by commerce to the motives which stimulate, and the comforts and enjoyments which reward, the labour of the industrious—as *nothing*, and to fix our attention exclusively on the favourable balance of gold and silver! This is like desiring a person to estimate the utility of a suit of clothes by the number and glare of the metal buttons with which they are fastened! And yet this rule for judging of the advantageousness of foreign commerce was long regarded as infallible by the generality of merchants and practical statesmen; and, until very recently, we were annually congratulated on the excess of our exports over our imports!

Manufacturing system.

But in addition to the erroneous notions respecting the precious metals, there were other circumstances which led to the establishment of the mercantile system, and the enacting of regulations subversive of the freedom of industry. The feudal governments established in the countries which formed the western division of the Roman empire, early degenerated into a system of anarchy and lawless oppression. The princes, unable to restrain the usurpations of the greater barons, or to control their violence, endeavoured to strengthen their influence and consolidate their power by attaching the cities and towns to their interests. For this purpose they granted them charters, which enfranchised the inhabitants, abolished every existing mark of servitude, and formed them into corporations, or bodies politic, to be governed by councils and magistrates of their own selection. The order and good government that were thus established in them, and the security enjoyed by the citizens, when the rest of the country was a prey to rapine and disorder, stimulated their industry, and gave them a vast ascendancy over the cultivators of the soil. It was from the towns that the princes derived the greater part of their supplies of money, and with their assistance they were enabled to control and subdue the pride and independence of the barons. But the townsfolk were not disinterested enough to take part with their sovereigns merely from gratitude for the original gift of their charters. They were continually soliciting new privileges. And it was not to be expected that princes whom they had laid under the greatest obligations, and by whom they were justly regarded as the most industrious and deserving portion of their subjects, should be at all disinclined to gratify their wishes. To enhance the value of their corporate rights, they were authorized to hinder all individuals, whether native or foreign, who had not obtained leave from them, from carrying on any trade or craft within their limits; to enable them to obtain cheaper food and materials, the exportation of corn and of the raw products used in their manufactures was prevented; and to secure a market for whatever articles they had to sell, heavy duties and prohibitions were imposed on such foreign articles as might come into competition with those made at home, at the same time that bounties were employed to force the exportation of the latter! Such were the principal features of the system of public economy adopted, in the view of encouraging domestic industry, in every country of Europe, in the fourteenth, fifteenth, sixteenth, and seventeenth centuries. The freedom of trade recognised by their ancient laws was almost totally destroyed. It would be easy to mention a thousand instances of the excess to which this artificial system was carried in England and elsewhere; but we shall only observe, as illustrative of its spirit, that by an act passed in 1678, for the encouragement of the woollen manufacture, it was ordered that all *dead bodies* should be wrapped in woollen shrouds!

But the exclusion of foreign competition, and the monopoly of the home market, did not satisfy the manufacturers and merchants. Having obtained all the advantage they could from the public, they next attempted to prey on each other. Those possessed of most influence were authorized to carry on particular branches of industry, to the exclusion of every one else. This abuse having been carried to an extreme in the reign of Elizabeth, who granted an infinite number of new patents, became at last so intolerable as to make all classes join in petitioning for its abolition. And this, after much opposition on the part of government, by whom the power of erecting monopolies was regarded as a very valuable branch of the prerogative, was effected by an act passed in the 21st of James I. But this act did not touch any of the fundamental principles of the mercantile or manufacturing system; and the privileges of bodies corporate were exempted from its operation.

In France the interests of the manufacturers were warmly espoused by Colbert, the celebrated minister of finance during the most splendid period of the reign of Louis XIV.; and the year 1664, when the tariff, compiled under Colbert's direction, was promulgated, has been sometimes considered, though improperly, as the æra of the manufacturing system.

These restrictions were zealously supported by the writers in defence of the mercantile system and the balance of trade. The facilities given to the exportation of manufactured goods, and the obstacles thrown in the way of their importation, seemed to them to be particularly well fitted for making the exports exceed the imports, and procuring a favourable balance. Instead, therefore, of regarding these regulations as the offspring of a selfish monopolizing spirit, they looked on them as having been dictated by the soundest policy. The manufacturing and mercantile systems were thus naturally blended together. The acquisition of a favourable balance of payments was the grand object to be accomplished; and heavy duties and restrictions on importation from abroad, and bounties and premiums on exportation from home, were the means by which it was to be attained! It cannot excite surprise that a system having so many popular prejudices in its favour, and which afforded a plausible and convenient apology for the exclusive privileges enjoyed by the manufacturing and commercial classes, should have early attained, or that it should still preserve, notwithstanding the overthrow of its principles, a powerful practical influence. Melon and Forbonnais in France; Genovesi in Italy; Mun, Sir Josiah Child, Davenant, the authors of the *British Merchant*, and Sir James Steuart in England, are the ablest writers who have espoused, some with more and some with fewer exceptions, the leading principles of the mercantile system.

"It is no exaggeration to affirm that there are but few political errors which have produced more mischief than the mercantile system. Armed with power, it commanded and forbid where it should only have *protected*. The regulating mania which it inspired tormented industry in a thousand ways to force it from its natural channels. It made each nation regard the welfare of its neighbours as incompatible with his own; hence the reciprocal desire of injuring and impoverishing each other; and hence that spirit of commercial rivalry which has been made the immediate or remote cause of the greater number of modern wars. This system stimulated nations to employ force or cunning to extort commercial treaties, productive of no real advantage to themselves, from the weakness or ignorance of others. It formed colonies that the mother country might enjoy the monopoly of their trade, and force them to resort exclusively to her markets. In short, where it has been productive of the least injury, it has retarded the progress of national prosperity; everywhere else it has deluged the earth with blood, and has depopulated and ruined some of those countries whose power and opulence it was supposed it would carry to the highest pitch." (Storch, *Traité d'Economie Politique*, tom. i., p. 122.)

Progress of commercial science in England.

The greater attention which began to be paid, in the seventeenth and in the earlier part of the last century, to subjects connected with finance, commerce, and agriculture, gradually prepared the way for the downfall of the mercantile system. The English writers preceded those of every other country in pointing out its defects, and in discovering the real nature and functions of money, and the true principles of commerce. The establishment of a direct intercourse with India did much to accelerate the progress of sound opinions. The precious metals have always been one of the most advantageous articles of export to the East.[1] And when the East India Company was established in 1600, leave was given them to export *foreign* gold coins or bullion of the value of L.30,000 a year, on condition of their importing, within six months after the termination of every voyage, except the first, as much gold and silver as should together be equal to the value of the silver they exported. But the Company's enemies contended that these conditions were not complied with, and that it was contrary to all principle, and highly injurious to the public interests, to permit the exportation of any quantity of bullion. The merchants and others interested in the India trade,—among whom we have to reckon Sir Dudley Digges, whose defence of the Company was published in 1615; Mun, who published a very able pamphlet in defence of the Company in 1621;[2] Misselden; and, more recently, Sir Josiah Child,—could not controvert the reasoning of their opponents without openly impugning some of the commonly received opinions regarding money. In such circumstances it might easily have been foreseen that prejudice would give way to interest. At first, however, the advocates of the Company did not contend, nor is there, indeed, any good reason for thinking that they were of opinion, that the exportation of gold and silver to the East Indies was beneficial, on the ground that the commodities brought back were of greater value. They contended that the Company did not export a greater quantity of bullion than their charter authorized; and they further contended that its exportation was advantageous, because the commodities imported from India were chiefly re-exported to other countries, where they obtained a greater quantity of bullion in exchange for them than they had originally sent to India.[1] But even this was an immense advance in the progress to a sounder theory. *C'est toujours le premier pas qui coute.* The advocates of the Company began gradually to assume a higher tone; and at length boldly contended that bullion was nothing but a commodity, and that its exportation should be as free as that of anything else. Nor were these opinions confined to the partners of the East India Company. They were gradually communicated to others; and many eminent merchants were taught to look with suspicion on several received maxims, and were in consequence led to acquire more correct and comprehensive views regarding commercial intercourse. The new ideas ultimately made their way into the House of Commons; and in 1663 the statutes prohibiting the exportation of foreign coin and bullion were repealed, and full liberty given to the East India Company and to private traders to export them in unlimited quantities.

---

[1] Pliny, when enumerating the spices, silks, and other eastern products imported into Italy, says, "Minimaque computatione millies centena millia sestertium annis omnibus, India et Seres, peninsulaque illa (Arabia) imperia nostro demunt." (*Hist. Nat.*, lib. xii., cap. 18.) Charles V. used to say that the Portuguese, who in his time engrossed almost the whole commerce of the East, were the common enemies of Christendom, inasmuch as they drained it of its treasure to export it to infidels! (Misselden on *Free Trade*, p. 24.)

[2] This pamphlet, which had become extremely rare, is included in the volume of early tracts on commerce reprinted for the Political Economy Club in 1856.

In addition to the controversies respecting the East India trade, the foundation of the colonies in America and the West Indies, the establishment of a compulsory provision for the support of the poor, the acts prohibiting the exportation of wool and the non-importation of Irish cattle, &c., drew an extraordinary portion of the public attention to questions of domestic policy. In the course of the seventeenth century a more than usual number of tracts were published on commercial and economical subjects. And although it must be admitted that the authors of the greater number are deeply imbued with the prevailing spirit of the age, there were some among them who rose far above the prejudices of their contemporaries, and have an unquestionable right to be regarded as the founders of the modern theory of commerce. They were the earliest teachers of those sound and liberal doctrines which show that the prosperity of states cannot be promoted by restrictive regulations, or by the depression of their neighbours; that the genuine spirit of commerce is inconsistent with the selfish and shallow policy of monopoly; and that the *self-interest* of mankind, not less than their duty, requires them to live in peace, and to cultivate a fair and friendly intercourse with each other.

Mr Mun.

We have already referred to Mun's treatise, entitled *England's Treasure by Foreign Trade.* It was first published in 1664; but there is good reason to suppose that it had been written many years previously. Mun's son, in the dedication to Lord Southampton, which he has prefixed to the work, says that his father "was, *in his time*, famous among merchants," a mode of expression which he would hardly have used had not a considerable period elapsed since his father's death; and Misselden, in his *Circle of Commerce*, published in 1623 (p. 36), refers to Mun's tract on the East India trade, and speaks of its author as being an accomplished and experienced merchant. Perhaps, therefore, we shall not be far wrong if we assume that the treatise on Foreign Trade was written so early as 1635 or 1640. At all events, the doctrines which it contains do not differ much from those which he had previously maintained in his pamphlet in defence of the East India Company, and some of the expressions are literally the same with those in the petition presented by that body to Parliament in 1628, which is known to have been written by Mun.[2] The extract we have previously given shows that his opinions, in so far as regards the balance of trade, were identical with those of his contemporaries. But we incline to think that, if not the first, he was one of the first, who endeavoured to show, and who in fact successfully showed, that a favourable balance could not be procured by restrictive regulations; that the exportation and importation of bullion, coin, and everything else, should be freely permitted; and that "violent measures will never bring gold or silver into a kingdom, or retain them in it." (Pp. 27, 92, &c., original edition.) Mun also distinctly lays it down, "that those who have wares cannot want money," and that "it is not the keeping of our money in the kingdom, but the necessity and use of our wares in foreign countries, and our want of other commodities, that causeth the vent and consumption on all sides, which causeth a quick and ample trade." (P. 43.[3]) Nor are these detached and incidental passages thrown out at random. The spirit which they breathe pervades the book, and forms part of the system of the author. His observations in answer to Malyne's, on some rather difficult questions connected with exchange, are both acute and ingenious.

Sir Josia Child.

The first edition of Sir Josiah Child's celebrated work on trade (*A New Discourse of Trade*, &c.) was published in 1668; but it was very greatly enlarged in the next edition, published in 1690. There are many sound and liberal doctrines advanced in this book. The argument to show that colonies do not depopulate the mother country is as conclusive as if it had proceeded from the pen of Malthus; and the just and forcible reasoning in defence of the naturalization of the Jews is highly creditable to the liberality and good sense of the writer, and discovers a mind greatly superior to existing prejudices. Sir Josiah has also some judicious observations on the laws against *forestalling* and *regrating*, on those limiting the number of apprentices, on corporation privileges, &c.

When treating of the laws relating to the exportation of wool, Sir Josiah lays it down, "that they that can give the best price for a commodity shall never fail to have it by one means or other, notwithstanding the opposition of any laws, or interposition of any power by sea or land; of such force, subtilty, and violence, is the general course of trade."

The radical defect of Sir Josiah Child's treatise consists in its being chiefly written to illustrate the advantages which he labours to show would result from reducing the legal rate of interest to four per cent.; an error into which he was led by mistaking the low interest of Holland for the principal cause of her wealth, when in truth it was mainly the result of her comparatively heavy taxation.

It is, however, worthy of remark, that this error was very soon detected. In the same year (1668) that Sir Josiah's treatise first appeared, a tract was published, entitled *Interest of Money Mistaken, or a Treatise proving that the Abatement of Interest is the Effect and not the Cause of the Riches of a Nation.* The author of this tract maintains the opinion afterwards held by Locke and Montesquieu, that the interest of money does not depend on statutory regulations, but that it varies according to the comparative opulence of a country; or rather according to the scarcity and abundance of money, increasing when the supply of money diminishes, and diminishing when it increases.[1] Having endeavoured to establish this plausible but erroneous doctrine, the author contends that Sir Josiah Child had totally mistaken the cause of the wealth of the Dutch, of which he says the lowness of interest was merely a consequence.

---

[1] Those who have not the original pamphlets may consult Macpherson's *History of Commerce*, vol. ii., pp. 297, 315, 511; Macpherson's *Account of the European Commerce with India*, pp. 94, 104; and Mr Robert Grant's *Sketch of the History of the Company*, p. 44, where they will find ample confirmation of what is stated above.

[2] This petition, and the reasons on which it is founded, were so well esteemed as to occasion its being reprinted in 1641.

[3] These expressions are in the petition of the Company, presented to Parliament in 1628.

Sir Wm. Petty's *Political Anatomy.*

In 1672 Sir William Petty published his celebrated tract, entitled the *Political Anatomy of Ireland.* In this work the mischievous influence of the act passed in 1664, prohibiting the importation of cattle, beef, &c., from Ireland, is ably exposed, and the advantage of an unconstrained internal commerce clearly set forth. "If it be good for England," says Sir William, "to keep Ireland a distinct kingdom, why do not the predominant party in Parliament, suppose the western members, make England beyond Trent another kingdom, and take tolls and customs upon the borders? Or why was there ever any union between England and Wales? And why may not the entire kingdom of England be further cantonized for the advantage of all parties?"

The great defect of the writings of Mun, Misselden, Child, and others, does not consist so much in their notions about the superior importance of the precious metals, or the balance of trade, as in those respecting the advantages which they supposed were derivable from importing durable rather than rapidly perishable commodities and luxuries. This, however, was an extremely natural opinion; and we need not be surprised that the early writers on commerce fell into an error, from which neither the profound sagacity of Locke, nor the strong sense of Harris, has been able to preserve them. But even so early as 1677, the fallacy of this opinion was perceived. In that year there appeared a small tract, entitled *England's Great Happiness, or a Dialogue between Content and Complaint;* in which the author contends, that if there be a demand for wine, fruit, and such like articles, their importation in exchange for money is advantageous; and, on this ground, he defends the French trade, which was loudly declaimed against by the practical men of that day. We shall make a short extract from this remarkable tract:—

"*Complaint.*—You speak plain; but what think you of the French trade, which draws away our money by wholesale? Mr Fortrey,[2] whom I have heard you speak well of, gives an account that they get L.1,600,000 a year from us.

"*Content.*—'Tis a great sum; but perhaps were it put to a vote in a *wise council,* whether for that reason the trade should be left off, 'twould go *in the negative.* For paper, wine, linen, Castile soap, brandy, olives, capers, prunes, kid-skins, taffaties, and such like, we cannot be without; and for the rest, which you are pleased to style *apes* and *peacocks* (although wise Solomon ranked them with gold and ivory), they set us all agog, and have increased among us many considerable trades. . . . . I must confess, I had rather they'd use our goods than money; but if not, I would not lose the getting of ten pound because I can't get an hundred; and I don't question but when the French get more foreign trade, they'll give more liberty to the bringing in foreign goods. I'll suppose John-a-Nokes to be a butcher, Dick-a-Styles to be an exchange man, yourself a lawyer; will you buy no meat or ribbands, or your wife a fine Indian gown or fan, because they will not truck with you for indentures which they have need of? I suppose no; but if you get money enough of others, you care not though you give it away in specie for these things. I think 'tis the same case."

The spirit of this tract may perhaps be better inferred from the titles of some of the dialogues. Among others, we have "To export money our great advantage;"—"The French trade a profitable trade;"—"Variety of wares for all markets, a great advantage;"—"High living, a great improvement to the arts;"—"Invitation of foreign arts, a great advantage;"—"Multitudes of traders, a great advantage," &c., &c. But its influence was far too feeble to arrest the current of popular prejudice. In the year after its publication (1678) the importation of French commodities was prohibited for three years. This prohibition was made perpetual in the reign of William III., when the French trade was declared to be a nuisance!—a principle, if we may so call it, which has been acted upon down to our own times.

In 1681 a pamphlet was published in defence of the East India Company, under the signature of "Philopatris," but evidently the production of Sir Josiah Child. In the Introduction to this pamphlet the following principles are laid down:—

"That all close monopolies (Sir Josiah contends that the East India Company does not come under this description), of what nature or kind soever, are destructive to trade, and consequently obstructive to the increase of the value of our lands."

"That silver or gold, coined or uncoined, though they are used for a measure of all other things, are no less a commodity than wine, oil, tobacco, cloth, or stuffs; and may, in many cases, be exported as much to the national advantage as any other commodity."

"That no nation ever was, or will be, considerable in trade, that prohibits the exportation of bullion." (P. 3.)

Sir Wm. Petty's *Quantulumcunque.*

In Sir William Petty's *Quantulumcunque,* published in 1682, the subject of money is ably treated, and the idea of draining England of her cash by an unfavourable balance successfully combated. "If some English merchants," it is said, "should be so improvident as to carry out money only, then the foreign merchants would buy up such English commodities as they wanted with money brought into England from their respective countries, or with such commodities as England likes better than money; for the vending of English commodities doth not depend on anything else but the use and need which foreigners have of them." Sir W. denies that "a country is the poorer for having less money;" and concludes by strongly condemning the laws regulating the rate of interest; observing, that there may as well be laws to regulate the rate of exchange and of insurance. (See pp. 3, 6, 8, original edition.)

Sir Dudley North.

But a tract, entitled *Discourses on Trade, principally directed to the Cases of Interest, Coinage, Clipping, and Increase of Money,* written by Sir Dudley North, and published in 1691, contains a far more able statement of the true principles of commerce than any that had then appeared.

We regret that our limits will not permit our giving so full an account as we could have wished of this extraordinary tract. The author is a most intelligent and consistent advocate of the great principles of commercial freedom. He is not, like the most eminent of his predecessors, well informed on one subject, and erroneous on another. He is throughout sound and liberal. His system is consentaneous in its parts, and complete. He shows that in commercial matters nations have the same interests as individuals; and exposes the absurdity of supposing that any trade advantageous to the merchant can be injurious to the public. His opinions respecting the imposition of a seignorage on the coinage of money, and the expediency of sumptuary laws, then in great favour, are equally enlightened.

---

[1] It has been generally supposed that Hume was the first who showed (in his *Essay on Interest*) the fallacy of this opinion, and who proved that the rate of interest does not depend on the abundance or scarcity of money, but on the abundance or scarcity of disposable capital compared with the demands of the borrowers and the rate of profit. This, however, is a mistake, the doctrine in question having been fully demonstrated in a pamphlet written by Mr Massie, entitled *Essay on the Governing Cause of the Natural Rate of Interest,* published two years before Mr Hume's Essay appeared.

[2] Mr Fortrey's pamphlet has been much referred to. It was published in 1663, and reprinted in 1673. It contains a very good argument in favour of inclosures. The reference in the text sufficiently explains the opinions of the writer in regard to commerce.

We subjoin from the Preface to this tract an abstract of the general propositions maintained in it:—

"That the whole world as to trade is but as one nation or people, and therein nations are as persons.

"That the loss of a trade with one nation is not that only, separately considered, but so much of the trade of the world rescinded and lost; for all is combined together.

"That there can be no trade unprofitable to the public; for if any prove so, men leave it off; and wherever the traders thrive, the public, of which they are a part, thrive also.

"That to force men to deal in any prescribed manner may profit such as happen to serve them; but the public gains not, because it is taking from one subject to give to another.

"That no laws can set prices in trade, the rates of which must and will make themselves. But when such laws do happen to lay any hold, it is so much impediment to trade, and therefore prejudicial.

"That money is a merchandise, whereof there may be a glut, as well as a scarcity, and that even to an inconvenience.

"That a people cannot want money to serve the ordinary dealing, and more than enough they will not have.

"That no man will be the richer for the making much money, nor have any part in it, but as he buys it for an equivalent price.

"That the free coynage is a perpetual motion found out, whereby to melt and coyn without ceasing, and so to feed goldsmiths and coyners at the public charge.

"That debasing the coin is defrauding one another, and to the public there is no sort of advantage from it; for that admits no character or value but intrinsick.

"That the sinking by alloy or weight is all one.

"That exchange and ready money are the same, nothing but carriage and re-carriage being saved.

"That money exported in trade is an increase to the wealth of the nation; but spent in war, and payments abroad, is so much impoverishment.

"In short, that all favour to one trade or interest is an abuse, and cuts so much of profit from the public."

Unluckily this admirable tract never obtained any considerable circulation. There is good reason, indeed, to suppose that it was designedly suppressed.[1] At all events, it speedily became excessively scarce; and we are not aware that it was ever referred to by any subsequent writer till it was noticed in the first edition of this article.[2]

The disordered state of the coin, and the proceedings relative to the great re-coinage, in the reign of William III., led to a great deal of discussion both in and out of Parliament, and contributed in no ordinary degree to diffuse juster notions respecting money and commerce. It was then that Mr Locke published his well-known tracts on Money,[3] They immediately obtained a very extensive circulation; and though infected with some very grave errors, had a powerful influence in preventing the adoption of Mr Lowndes's proposal for degrading the standard of the coin, and in contributing to establish the true theory of money. The restoration of the currency was not, however, effected without great opposition. A large minority in Parliament supported Lowndes's views; and they were also supported by a number of writers. Of these, Mr Nicholas Barbon seems to have been one of the ablest. In his tract, entitled *A Discourse concerning Coining the New Money Lighter*, published in 1696, he detected several of the errors into which Locke had fallen; and he had the further merit of demonstrating the fallacy of the popular opinions respecting the balance of trade; and of showing that bullion would never be sent abroad in payment of an unfavourable balance, unless it were at the time the cheapest and most profitable article of export.

Mr Barbo

The inferences deduced by Barbon from his investigations into the balance of trade and foreign exchange are:—

"That a trading nation is made rich by traffic and the industry of the inhabitants—and that the native stock of a nation can never be wasted.

"That no sort of commodities ought to be totally prohibited—and that the freer trade is, the better the nation will thrive.

"That the poverty and riches of a nation do not depend on a lesser or greater consumption of foreign trade, nor on the difference of the value of those goods that are consumed.

"That the balance of trade is a notion that serves rather to puzzle all debates of trade, than to discover any particular advantages a nation may get by regulating of trade.

"That the balance of trade (if there be one) is not the cause of sending away the money out of a nation; but that proceeds from the difference of the value of bullion in several countries, and from the profit that the merchant makes by sending it away more than by bills of exchange.

"That there is no occasion to send away money or bullion to pay bills of exchange, or balance accounts.

"That all sorts of goods, of the value of the bill of exchange, or the balance of the account, will answer the bill, and balance the account as well as money." (P. 59.)

It is singular that a writer possessed of such just and enlarged opinions respecting the principles of commercial intercourse, and who had shown that bullion differed in no respect from other commodities, should have maintained that the value of coins depended on the stamp impressed on them by government. This gross and unaccountable error destroyed the effect of Barbon's tract; and was, most probably, the cause of the oblivion into which it very soon fell, and of its never having attracted that attention to which, on other accounts, it was entitled.

Dr Davenant.

The commercial writings of Dr Davenant, inspector-general of imports and exports, were published in the interval between 1695 and 1711. Though a partizan of the mercantile system, Davenant had emancipated himself from many of the prejudices of its more indiscriminate and zealous supporters. He considered a watchful attention to the balance of trade, and its "right government," as of the highest importance; but he did not consider that wealth consisted exclusively of gold or silver; or that prohibitions and restrictions should be rashly imposed, even on the intercourse with those countries with which the balance was supposed to be unfavourable. But we are far from thinking that his commercial writings deserve the eulogies that have been bestowed on them, or that they had any material effect in accelerating the progress of sound commercial science. They do not contain a single principle not to be found in the work of Sir Josiah Child. Some of Davenant's paragraphs are exceedingly good; but the treatises of which they form a part are remarkably inconclusive, and are for the most part pervaded by narrow and contracted views. There is no evidence to show that he was at all aware of the influence of commerce in facilitating the production of wealth by giving rise to the territorial division of labour, and enabling each people to devote itself, in preference, to those employments for the successful prosecution of which they have some peculiar advantage.[1]

---

[1] See the Honourable Roger North's Life of his brother, the Honourable Sir Dudley North, p. 179.

[2] This tract, and the greater number of those referred to in this article, with many more of equal value and importance, are included either in the collection of early tracts on trade reprinted by the Political Economy Club of London in 1856, or in the four volumes of economical tracts that have been since reprinted by Lord Overstone. This last is one of the most valuable contributions that have ever been made to the illustration of that science of which the noble lord is so great a master. It has been a means of preserving many valuable publications, some of which were extremely scarce, and ran an imminent risk of being entirely lost, and of making them available to the historians and economists of this and future ages. It is much to be wished that other opulent noblemen and gentlemen would follow so excellent an example, by collecting and reprinting the scarcest and most valuable tracts in other departments of knowledge.

[3] *Considerations on the Lowering of Interest and Raising the Value of Money*, 1691; *Further Considerations concerning Raising the Value of Money*, 1695.

Jacob Vanderlint.

In 1734 Jacob Vanderlint, who describes himself as a tradesman, published his tract, entitled *Money Answers all Things*. Dugald Stewart has referred to it in the Appendix to his Life of Adam Smith, and has quoted some passages illustrative of the advantages of commercial freedom, which, he says, "will bear a comparison, both in point of good sense and liberality, with what was so ably urged by Mr Hume twenty years afterwards, in his *Essay on the Jealousy of Trade*." Vanderlint closes his pamphlet with an argument in favour of the substitution of a territorial tax in place of every other,—an idea borrowed from Locke, and subsequently adopted by the French economists.

Mr Richardson.

In 1744,[2] Mr Richardson, an extensive merchant, published an *Essay on the Causes of the Decline of Foreign Trade*. This essay has been frequently referred to by Adam Smith, and it deserved his notice. Richardson is an intelligent and decided enemy of restrictions, monopolies, and prohibitions. To give full freedom to industry, he proposed that corporation privileges should be abolished, and that the existing taxes should be repealed, and replaced by a *single tax* laid on the consumers of luxuries, proportionally to their incomes. The following extracts will give an idea of the spirit and ability which pervades this essay:—

"In the *Memoirs of De Witt* it is said, 'that restraint is always hurtful to trade;' the reason whereof is plain, for nature has given various products to various countries, and thereby knit mankind in an intercourse to supply each other's wants. To attempt to sell our products, but to buy little or none from foreigners, is attempting an impossibility, acting contrary to the intent of nature, cynically, and absurdly, and, as ours is a populous manufacturing country, might be prejudicial to our interests; for, could we raise all necessaries and vanities within ourselves, this intercourse designed by nature would be destroyed; and then, how is our navy, our only bulwark, to be maintained?" (P. 147.)

"Trade cannot, will not, be forced; let other nations prohibit, by what severity they please, interest will prevail; they may embarrass their own trade, but *cannot hurt a nation whose trade is free so much as themselves*. Spain has prohibited our woollens; but had a reduction of our taxes brought them to their natural value only, they would be the cheapest in Europe of their goodness, consequently must be more demanded by the Spaniards, be smuggled into their country in spite of their government, and sold at better prices; their people would be dearer clothed, with duties and prohibitions, than without, consequently must sell their oil, wine, and other commodities dearer; whereby other nations, raising the like growths, would gain ground upon them, and their balance of trade grow less and less. But should we, for that reason, prohibit their commodities? By no means; for the dearer they grow, no more than what are just necessary will be used; their prohibition does their own business; some may be necessary for us; what are so, we should not make dearer to our own people; some may be proper to assort cargoes for other countries, and why should we prohibit our people that advantage? *Why hurt ourselves to hurt the Spaniards?* If we would retaliate effectually upon them for their ill intent, handsome premiums given to our plantations to raise the same growths as Spain might enable them to supply us cheaper than the Spaniards could do, and establish a trade they could never recover. Premiums may gain trade, but prohibitions will destroy it." (P. 163.)

Mr Richardson applies the same argument to expose the injurious influence of the restraints on the trade with France. "I allow," he says, "that Britain should be always vigilant over the designs of France, but need not be afraid of her power. Her wise regulations in trade should be the objects we should keep our eyes upon, and outdo her if possible; or else, as she rises we must sink. But it is our comfort that our remedy is always in our own hands; nor can there be any solid reason for the nation's paying dearer to other countries for goods we could buy cheaper in France. Would any wise dealer in London buy goods of a Dutch shopkeeper for 15d. or 18d. when he could have the same from a French shopkeeper for 1s.? Would he not consider that, by so doing, he would empty his own pockets the sooner, and that, in the end, he would greatly injure his own family by such whims? And shall this nation commit an absurdity that stares every private man in the face? .... The certain way to be secure is to be more powerful,—that is, to extend our trade as far as it is capable of; and as restraints have proved its ruin, to reject them and depend on freedom for our security, bidding defiance to the French, or any nation in Europe, that took umbrage at our exerting our natural advantages." (P. 184.)

We do not know that the impolicy of restrictions on the importation of foreign corn has ever been more triumphantly exposed than in the following passage:—"Every home commodity, in a free trade, will find its natural value; for though that fluctuates, as of necessity it must, according to the plentifulness or scarcity of seasons, yet, for the home consumption, every home commodity must have great advantage over the foreign, as being upon the spot, and free from freight, insurance, commission, and charges, which on the produce of lands, being all bulky commodities, must in general be about 15 per cent., and a greater advantage cannot be given without prejudice; for 15 per cent. makes a great difference in the price of necessaries between the nation selling and the nation buying, and is a great difficulty on the latter, but, arising from the natural course of things, cannot be helped, though it is a sufficient security to the landholder that foreigners can never import more necessaries than are absolutely required; and I presume in such cases they have more charity than to starve the people merely for an imaginary profit, which yet would prove their ruin in the end; for it is a fallacy and an absurdity to think to raise the value of lands by oppressions on the people that cramp their trade; for if trade declines, the common people must either come upon the parish, or fly for business to our neighbours. In the first case, they become a heavy tax on the rich, and, instead of buying the produce of their lands, must have it given them; and, in the second case, when the consumers are gone, what price will the produce of land bear?" (P. 56.)

---

[1] The progress of enlarged and liberal opinions with regard to commerce seems to have been in no small degree counteracted by the publication of the *British Merchant*. This work was written by some of the first merchants of their time to expose the alleged defects in the commercial treaty with France negotiated by Queen Anne's Tory administration in 1713. It consists of a series of papers published weekly, and afterwards collected in three volumes. Public opinion being very much against the treaty, the *British Merchant* enjoyed a large share of popularity. Its authors appeared to have been thoroughly imbued with all the prejudices of the mercantile sect; and the work is now only deserving of notice as containing the fullest exposition of their peculiar doctrines.

[2] We quote from the edition of the Essay published at Edinburgh in 1756. The first edition, in 4to, was published in 1744.

Mr Hume.

Mr Harris.

Of a work so well known as Mr Hume's *Political Essays* (published in 1752) it is superfluous to speak. The ability with which he has combated the prejudice against the French trade, and ridiculed the fear of being deprived of a sufficiency of bullion; the liberality and expansion of his views respecting commerce; the beauty of his style, and the aptness of his illustrations, cannot be too highly praised. It did not, however, enter into his plan to give a systematic view of the influence of commerce, nor did he institute any analysis of the sources of wealth. Mr Harris endeavoured to supply the latter deficiency; and his *Essay on Money and Coins*, published in 1757, is perhaps on the whole the best economical treatise that had appeared previously to the *Wealth of Nations*. We have already noticed Harris's mistake in supposing that it was more profitable to import durable rather than rapidly consumable commodities; and, as a writer on commerce, he is undoubtedly inferior to Sir Dudley North and Mr Richardson. But the comprehensive and able manner in which he has treated the subject of money, the skill with which he has illustrated the influence of the division of labour, and the near approach he has made to some of the fundamental doctrines of Smith, if they do not give him a pre-eminence, certainly place him in the first rank among his precursors.

Early Italian writers on commerce.

We have been induced to treat of the progress of commercial science in England at considerable length, partly on account of the interest and importance of the subject, and partly because it has been but little investigated. Say and other continental writers contend that the Italians and French were the first who discovered and established the just principles of commercial intercourse. But the details now given prove the indisputable priority of the English. The economical works of Davanzati, Serra, Turbolo, and Scaruffi are almost wholly occupied with a discussion of the effects of a forced reduction of the standard of money. They deserve credit for having opposed all tampering with the currency; but the arguments they employ to show its injustice and impolicy are stated with much greater brevity and force in Sir Robert Cotton's speech before the Privy Council in 1626. The *Discurso Economico* of Bandini, the earliest writer on commerce whose works have been thought worthy of a place in the voluminous collection of Italian works on political economy[1] was published so late as 1737. Belloni and Algarotti's *Essays on Commerce*, both very inferior to the works of Child and North, were published, the former in 1750, and the latter in 1763.

Early French writers on commerce.

The French have still less claim than the Italians to be considered the discoverers of the true principles of commerce. There are many just and striking observations on the injury France sustained from the want of a free internal traffic, and the oppressiveness of taxation, in the *Dixme Royale* of Marshal Vauban, written in 1698. But Vincent de Gournay, whom the French state to be one of the earliest of their authors who entertained comprehensive and liberal notions in regard to commerce, was born so late as 1712.[2] Gournay published translations of the treatise of Sir Josiah Child, and of a tract by Sir Thomas Culpepper, at Paris in 1752. So slow was the progress of economical science in France, that even Montesquieu has a chapter entitled, "A quelles nations il est désavantageux de faire le commerce."[3]

System of the French Economists.

M. Quesnay.

But neither the efforts of the English nor French writers in favour of the freedom of commerce and industry had any considerable influence on the mercantile system. Their opinions respecting the nature of wealth and the causes of national opulence being confused and contradictory, their arguments in favour of a liberal system of commerce had somewhat of an empirical appearance, and failed to make that impression which is always made by arguments founded on well-established principles, and shown to be consistent with experience. Locke, as will be afterwards seen, entertained correct opinions respecting the paramount influence of labour in the production of wealth; but he does not appear to have been aware of their value, and did not again refer to them. And though Harris adopted Locke's views, and deduced from them some important practical inferences, his general reasonings are merely introductory to his *Treatise on Money*, and are not thrown into a scientific form. On the whole it would seem that the celebrated M. Quesnay, a physician attached to the court of Louis XV., was the first who investigated the sources of wealth, in the view of ascertaining the fundamental principles or natural laws on which national prosperity is mainly dependent; and by so doing he gave to political economy a systematic form, and raised it to the rank of a science. Having been brought up in the country, Quesnay was naturally inclined to regard agriculture with more than ordinary partiality. Its depressed state in France made him set about discovering the causes which had prevented its making that progress which the industry of the inhabitants, the fertility of the soil, and the excellence of the climate seemed to ensure. In the course of this inquiry he became convinced that the prohibition of exporting corn to foreign countries, and the preference given in the system of Colbert (which continued in the ascendant) to manufactures and commerce over agriculture, formed the most powerful obstacle to the improvement of the latter. But Quesnay did not satisfy himself with exposing the injustice of this preference and its pernicious consequences. His zeal for the interests of his favourite pursuit led him not merely to place it on the same level with the other great departments of industry, but to raise it above them, by endeavouring to show that agriculture is the only species of industry by which the riches of a nation can be increased. Founding on the fact, that everything which either ministers to our wants or gratifies our desires, must be originally derived from the earth, Quesnay assumed as a self-evident truth, that the earth is the only source of wealth, and held that industry is altogether incapable of producing any new value, except when employed in its culture, including therein the working of fisheries and mines.[1] His observance of the effects produced by the vegetative powers of nature, and his inability to explain the true origin and causes of rent, confirmed him in his opinion. The circumstance, that of all who engage in industrial undertakings, none but the cultivators of the soil pay rent for the use of natural agents, appeared to him to prove beyond all question that agriculture is the only variety of industry which yields a nett surplus (*produit net*) over and above the expenses of production. He admitted that manufacturers and merchants are highly useful; but as they realize no nett surplus in the shape of rent, he contended that they added no greater value to the commodities they manufactured or carried from place to place than was barely equivalent to the capital or stock consumed in these operations. These principles once established, it followed that landlords, farmers, and the labourers employed in agriculture are the only *productive* classes; and that the industry of manufacturers and traders being *unproductive*, their means of subsistence and wealth must be wholly derived from the agriculturists. It further followed that the expenses of government, and the various public burdens, however imposed, are really defrayed out of the *produit net*, or rent of the landlords: and consistently with this principle, Quesnay proposed that the existing taxes should be repealed, and that a single tax (*l'impôt unique*), laid directly on the produce of the land, should be imposed in their stead.

---

[1] *Scrittori Classici Italiani di Economia Politica*. The publication of this collection of the works of her economical writers does honour to Italy, or rather to Napoleon, by whom it was liberally patronized. It was begun in 1803, and finished in 1805, in 50 volumes 8vo.

[2] See Dupont's edition *Des Œuvres de M. Turgot*, tom. iii., p. 311.

[3] Maupertuis, in his *Eloge de Montesquieu*, candidly admits that France is indebted for the science of commerce, finance, and population, to England. The passage is curious:—"Comme le plan de Montesquieu," he observes, "renfermoit tout ce qui peut être utile au genre humain, il n'a pas oublié cette partie essentielle qui regarde le commerce, les finances, la population; science *si nouvelle parmi nous*, qu'elle n'y a encore point de nom. Ce'st *chez nos voisins qu'elle est née*; *et elle y demeura jusque à ce que M. Melon lui fit passer le mer.*" Melon's work, *Essai Politique sur le Commerce*, was published in 1734. It is entirely founded on the principles of the mercantile system. Mr Bindon translated it into English, and published it, along with some rather valuable annotations and remarks, at Dublin in 1739. Melon had advocated the ruinous policy of raising the denomination of the coin. This gave occasion to the publication of an acute work by Dutot, entitled *Réflexions Politiques sur les Finances et le Commerce*, 2 tomes 12mo, 1738. Dutot's work was in its turn very ably criticised by Duverney in his *Examen des Réflexions Politiques sur les Finances*, &c., 2 tomes 12mo, 1740. These works contain a great deal of curious and interesting information respecting French finance. Duverncy's account of the Mississippi scheme is particularly good.

The *economical table* of M. Quesnay—"Cette formule étonnante," says Dupont, "qui peint la naissance, la distribution, et la reproduction des richesses, et qui sert à calculer avec tant de sureté, de promptitude, et de précision, l'effet de toutes les opérations relatives aux richesses"—was published at Versailles in 1758.

But Quesnay, though deeply impressed with the superior importance of agriculture, did not solicit for it any exclusive favour or protection. He successfully contended that the advantage of the agriculturists, and of all classes, would be best promoted by establishing a perfectly free system. It could never, he said, be for the interest of the proprietors and cultivators of the soil to discourage the pursuits, or fetter the industry, of merchants, artificers, and manufacturers; for the greater their liberty, the greater would be their competition, and the cheaper their products. Neither, on the other hand, could it ever be for the interest of the unproductive classes to injure the agriculturists by preventing them from exporting their produce, or subjecting them to restrictive regulations. Cultivators who enjoy the greatest degree of freedom prosecute their business under the most favourable circumstances; and their nett surplus (*produit net*)—the only fund whence any accession to the public wealth can be derived—attains in consequence to the largest dimensions. According to this "liberal and generous system" (*Wealth of Nations*, p. 303[2]), the establishment of perfect liberty, perfect security, and perfect justice, is the only, as it is the infallible, means of securing the highest degree of prosperity to all classes.

"On a vu" says the commentator of this system, M. Mercier de la Rivière, "qu'il est de l'essence de l'ordre que l'intérêt particulier d'un seul ne puisse jamais être séparée de l'intérêt commun de tous; nous en trouvons une preuve bien convaincante dans les effets que produit naturellement et nécessairement la plénitude de la liberté qui doit regner dans le commerce, pour ne point blesser la propriété. L'intérêt personnel, encouragée par cette grande liberté, presse vivement et perpétuellement chaque homme en particulier, de perfectionner, de multiplier les choses dont il estvendeur, de grossir ainsi la masse des jouissances qu'il peut procurer aux autres hommes, afin de grossir, par ce moyen, la masse des jouissances que les autres hommes peuvent lui procurer en échange. *Le monde* alors *va de lui-même;* le désir de jouir, et la liberté de jouir, ne cessant de provoquer la multiplication des productions et l'accroissement de l'industrie, ils impriment à toute la société un mouvement qui devient une tendance perpétuelle vers son meilleur état possible." (Tome ii., p. 444.[3])

We shall have other opportunities of fully examining the principles of this theory. At present it is sufficient to remark that, in assuming agriculture to be the only source of wealth, because the matter of commodities is derived from the earth, Quesnay and his followers mistook altogether the nature of production, and really supposed wealth to consist of matter. But, in its natural state, matter is rarely possessed of utility, and is always destitute of value. The labour bestowed on its appropriation, and in fitting it for and applying it to our use, is the only means by which it acquires exchangeable value, and becomes wealth. The latter is not produced by adding to the contents of our globe, these being susceptible neither of augmentation nor diminution, but by giving utility to matter already in existence. And it will be immediately seen, that the labour employed in manufactures and commerce is as productive of utility, and consequently of wealth, as that employed in agriculture. Neither is the cultivation of the soil, as Quesnay supposed, the only variety of industry which yields a surplus over the expenses of production. When none but the best soils are cultivated, and when, consequently, agriculture is most productive, no rent, or *produit net*, is obtained from the land; and it is only after recourse has been had to poorer soils, and when the productive powers of the labour and capital employed in cultivation begin to diminish, that rent begins to appear; so that, instead of its being any proof of the superior productiveness of agricultural industry, rent is a consequence of its becoming comparatively less productive! The opinion of Quesnay, that man derives no assistance from the productive powers of nature, if he be not employed in agriculture, is totally destitute of foundation. It will be shown in a subsequent part of this article, that the manufacturer and merchant derive fully as much assistance from these powers as the agriculturist, fisher, or miner.

---

[1] "Cherchant d'où vient les richesses des nations, Quesnay trouva qu'elles ne naissent que des travaux dans lequels la *Nature et la Puissance Divine* concourent avec les efforts pour produire ou faire recueillir des productions nouvelles: de sorte qu'on ne peut attendre l'augmentation des ces richesses que de la cultivation, de la pêche, et de l'éxploitation des mines, et des carriers." (See the "Notice sur les Economistes," by one of the most zealous of the sect, Dupont de Némours, in the *Œuvres de Turgot*, tom. iii., p. 312.)

[2] M'Culloch's edition, 1 vol. 8vo.

[3] That Quesnay is entitled to the merit of originality cannot, we think, be disputed. He had certainly, however, been anticipated in several of his peculiar doctrines by some English writers of the previous century. The fundamental principles of the economical system are distinctly and clearly stated in a tract entitled *Reasons for a Limited Exportation of Wool*, published in 1677. "That it is of the greatest concern and interest to the nation," says the author of the tract, "to preserve the nobility, gentry, and those to whom the land of the country belongs, at least, much greater than a few artificers employed in working the superfluity of our wool, or the merchants who gain by the exportation of our manufactures, is manifest—1. Because they are the masters and proprietaries of the foundation of all the wealth in this nation, all profit arising out of the ground, which is theirs; 2. Because they bear all taxes and public burdens, which, in truth, are only borne by those who buy, and sell not; all sellers raising the price of their commodities, or abating of their goodness, according to their taxes." (Not being able to procure the pamphlet itself, we quote from the extract given in Mr Smith's *Memoirs of Wool*, vol. i., p. 254.) In 1696 Mr Asgill published a treatise entitled *Several Assertions Proved, in order to Create Another Species of Money than Gold*, in support of Dr Chamberlayne's proposition for a land bank. We extract from this treatise the following passage, breathing, as Dugald Stewart has justly observed, the very spirit of Quesnay's philosophy. "What we call commodities is nothing but land severed from the soil. Man deals in nothing but earth. The merchants are the factors of the world, to exchange one part of the earth for another. The king himself is fed by the labour of the ox; and the clothing of the army and the victualling of the navy must all be paid for to the owner of the soil as the ultimate receiver. All things in the world are originally the produce of the ground, and there must all things be raised." (This passage has been quoted in Lord Lauderdale's *Inquiry into the Nature and Origin of Public Wealth*, 2d ed., p. 109.) These passages are interesting as exhibiting the first germs of the theory of the Economists. But there is no reason to suppose that Quesnay was aware of the existence of either of the tracts referred to. The subjects treated in them were of too local a description to excite the attention of foreigners; and Quesnay was too candid to conceal his obligations, had he really owed them any. It is probable he may have seen Locke's treatise on *Raising the Value of Money*, where the idea is thrown out that all taxes fall ultimately on the land. But there is an immeasurable difference between the suggestion of Locke and the well-digested system of Quesnay.

But though the theory of the Economists, considered in reference to the fundamental principles of the science, be as erroneous as that to which it was opposed, its novelty and ingenuity, its systematical and consentaneous form, the liberal system of commercial intercourse which it recommended, and the benevolent and excellent character of its founder, speedily obtained for it a very high degree of reputation. The opinions of Quesnay were early communicated to, and zealously espoused by, the Marquis de Mirabeau, Mercier de la Rivière, Dupont de Némours, St Peravy, and others; and were afterwards advocated by Turgot, one of the most distinguished statesmen of whom France has to boast;[1] and by Letrosne, Condorcet, Raynal, and most of the succeeding French writers on commerce and finance. Their practical influence on the legislation of France has also been considerable. In 1763 the free transportation of corn from one province to another was permitted; and in 1764 liberty was given to export it to foreign countries whenever the home price did not exceed thirty livres the septier (48s. the quarter). This last edict, after being suspended in 1770, was again revived in 1778 during the administration of Turgot. But the facility given to the imposition of the *contribution foncière* may be considered as the greatest practical achievement of the Economists; and there is reason to fear that it will long continue to afford a palpable proof of the fallacy of their doctrines.[2]

Notwithstanding the defects of their theory, the labours of the Economists contributed powerfully to accelerate the progress of this science. In reasoning on subjects connected with national wealth, it was henceforth found to be necessary to subject its sources, and the laws which regulate its production and distribution, to a more accurate and searching analysis. In the course of this examination, it was speedily ascertained that the mercantile and economical theories were alike erroneous and defective; and that to establish the science on a firm foundation, it was necessary to take a much more extensive survey, and to seek for its principles, not in a few partial and distorted facts, or in metaphysical abstractions, but in the connection subsisting among the various phenomena manifested in the progress of civilization. The Count di Verri, whose *Meditations on Political Economy* were published in 1771, pointed out the fallacy of the opinions entertained by the Economists respecting the superior productiveness of agriculture; and showed that all the operations of industry really consist of modifications of matter already in existence.[3] But Verri did not trace the consequences of this important principle; and, possessing no clear or definite notions of what constituted wealth, he did not attempt to discover the means by which its production might be promoted. He made several valuable additions to particular branches of the science, and had sufficient acuteness to detect the errors in the systems of others; but the task of constructing a better system in their stead required talents of a far higher order.

Wealth of Nations.

At length, in 1776, our illustrious countryman, Adam Smith, published the *Wealth of Nations*—a work which has done for political economy what the *Principia* of Newton did for physics, and the treatise *De Jure Belli ac Pacis* of Grotius for international law. In this work the science was, for the first time, treated in its fullest extent, and many of its fundamental principles placed beyond the reach of cavil and dispute. In opposition to the Economists, Smith showed that *labour* is the only source of wealth, and that the desire of individuals to improve their fortunes and rise in the world occasions its accumulation. He next traced the means by which the powers of labour may be rendered most effective; and showed that it is productive of wealth when employed in manufactures and commerce, as well as in the cultivation of the land. Having established these principles, Smith showed, in opposition to the commonly received opinions of the merchants and statesmen of his time, that wealth did not consist in the abundance of gold and silver, but in that of the various necessaries, conveniences, and enjoyments of human life; and he further showed that individuals are always the best judges of what is for their own interest, and that, in prosecuting branches of industry advantageous to themselves, they necessarily prosecute such as are advantageous to the public.[1] Thence he drew his grand inference, that every regulation intended to force industry into particular channels, or to determine the commercial intercourse to be carried on between different parts of the same country, or between distant and independent countries, is impolitic and pernicious—injurious to the rights of individuals, and adverse to the progress of real opulence and lasting prosperity.

---

[1] Turgot's *Réflexions sur la Formation et la Distribution des Richesses*, published in 1771, is certainly the best of all the works founded on the principles of the Economists, and is, in some respects, the best work on political economy published previously to the *Wealth of Nations*.

[2] Exclusive of the *Réflexions* of Turgot, the following are the principal works published by the French Economists:—*Tableau Economique, et Maximes Générales du Gouvernement Economique*, par François Quesnay, 4to, Versailles, 1758; *Théorie de l'Impôt*, par M. de Mirabeau, 4to, 1760; *L'Ami des Hommes*, par M. de Mirabeau, 7 tomes, 1760, &c.; *Eléments de la Philosophie Rurale*, par M. de Mirabeau, 3 tomes 12mo, 1763; *L'Ordre Naturel et Essentiel des Sociétés Politiques*, par Mercier de la Rivière, 4to, et 2 tomes 12mo, 1767; *Sur l'Origine et Progrès d'une Nouvelle Science*, par Dupont de Némours, 1767; *La Physiocratie, ou Constitution Naturelle du Gouvernement le plus avantageux aux genre humain*, par Quesnay, 2 tomes, 1767; *Lettres d'un Citoyen à un Magistrat, sur les Vingtièmes et les âutres Impôts*, par l'Abbé Baudeau, 1768; *Mémoire sur les Effets de l'Impôt Indirect*, par St Peravy, 12mo, 1768.

[3] "Alcuni benemeriti scrittori, rattristati dai gravi disordini, che soffrono i popoli per le gabelle, sono passati all'estremo de considerare ingiusto e mal collocato il tributo se non ripartito sui fondi di terra, e colla creazione di un linguaggio ascetico, hanno eretta la setta degli economisti, presso la quale ogni uoma che non adoperi l'aratro, e un essere sterile, e i manifattore si chiamano una *classe sterile*. Rispettando il molto di vero e di utile che da essi è stato scritto, io non saprei associarmi alla loro opinione ne sul tributo, ne su di questa pretesa classe sterile. La riproduzione e attribuibile alla manifattura ugualmente, quanto al laroro de Campi. Tutti i fenomini dell' universo, sieno essi prodotti dalla mano dell'uomo o vero dalle universali leggi della fisica, non ci danno idea di attuale *creazione*, ma unicamente di una *modificazione* della materia. *Accostare seperare* sono gli unici elementi che l'ingegno umano ritrova analizando l'idea della *riproduzione;* e tanto e riproduzione *di valore e di richezza* se la terra, l'aria, e l'aqua ne'campi si trasmutino in grano, come se colla mano dello uomo il glutine di un insetto si trasmuti in velluto, o vero alcuni pezzetti di metallo si organizzino a formare una ripetizione. Degli intieri citta, e degli stati intieri campano non d'altro che sul prodotto di questa fecondissima *classe sterile*, la di cui riproduzione comprende il valore della materia prima, la consumazione proporzionata delle mani impiegatevi, e di piu quella porzione che fa arrichire chi ha intrapresa la fabbrica e chi vi s'impiega con felice talento." (*Meditazioni sulla Economia Politica*, § 3.)

It may here, perhaps, be necessary to observe that, in laying it down that individuals are the "best judges" of what is best for themselves, the phrase is not to be taken absolutely, but conditionally, or as meaning the best in their circumstances, with their knowledge, views, and means of compassing their ends. People in a different situation, with more extensive information, able to make a more correct estimate of the ends proper to be sought after, and possessing more efficient means for their attainment, would probably act differently. But in legislating, men should be taken for what they really are, and not for what it may be supposed they should be. And though it were otherwise, legislators are rarely more advanced than those for whom they legislate, and are extremely apt to be biassed by party and selfish considerations. Hence the true line of policy—allow all individuals at all times to prosecute what they believe to be their interest in their own way, provided only they do not encroach on the rights of others. When they are left to their own guidance, their constant endeavour is to find out better methods of effecting their objects; and they seldom fail to profit by such new lights, inventions, and discoveries, as may come to their knowledge. And while they have every facility, they have every motive to get into the right path, or that by following which they may best advance themselves. But when they are kept in a state of pupilage and dictated to by others, their talents are but little exerted, and they become less enterprising, and care less about the progress of discovery. At the same time, too, that their energies are paralysed, and that they are injuriously affected by the ignorance, the crotchets, and the prejudices of their self-sufficient guides, they cannot abandon the path chalked out for them, though they may have ascertained that it would be greatly for their advantage to leave it, and to enter upon a different one. The pretension to direct others what they should and should not do, and with whom or in what they should deal or not deal, is, in truth, so excessively overweening, and so certain to be abused, that it could be safely entrusted only to omniscience. And it could nowhere be worse placed than in the hands of individuals or legislatures, who, to use the words of Smith, had folly and presumption enough to fancy themselves fit to exercise it.

The fact, that traces of most part of the principles referred to above, and that the distinct statement of some of the more important amongst them, may be found in the works of previous writers, detracts but little, if anything, from the merits of Smith. In adopting the discoveries of others, he made them his own; he demonstrated the truth of principles on which his predecessors had in most instances stumbled by chance; separated them from the errors by which they were encumbered; traced their remote consequences; pointed out their limitations; showed their practical importance and real value; and reduced them into a consistent and well-compacted system. We do not, however, mean to say that Smith produced a perfect theory. Undoubtedly there are errors, and those, too, of no slight importance, in the *Wealth of Nations*. The principles already noticed, and which form its basis, are unimpeachable. Smith, however, has not always reasoned correctly from them, and he has occasionally introduced others, which a more careful observation and analysis has shown to be ill-founded. But after every allowance has been made for the defects in his great work, enough remains to justify us in considering him as the real founder of the science. Though he has not left a perfect treatise, he has left one which contains a greater mass of useful and universally interesting truths than have ever been given to the world by any other individual; and he has pointed out and smoothed the route by following which subsequent philosophers have been enabled to perfect much that he had left incomplete, to rectify the mistakes into which he fell, and to make many new and important discoveries. Whether, indeed, we refer to the soundness of its leading doctrines, to the liberality and universal applicability of its practical conclusions, or to the powerful and beneficial influence it has had on the improvement of economical science, and on the policy and destiny of nations, the *Wealth of Nations* must be placed in the foremost rank of those works that have done most to liberalize, enlighten, and enrich mankind.[2]

Distinction between politics and political economy.

The practical part of this science was long confounded with that of politics; and it is undoubtedly true that they are very intimately connected, and that it is frequently impossible to treat those questions which strictly belong to the one without referring more or less to the principles and conclusions of the other. But in their leading features they are sufficiently distinct. The laws which regulate the production and distribution of wealth are the same in every country and stage of society. Those circumstances which are favourable or unfavourable to the increase of riches and population in a republic may equally exist, and will have the same effects, in a monarchy. That security of property, without which there can be no steady and continued exertion,—that freedom of engaging in every different branch of industry, so necessary to call the various powers and resources of human talent and ingenuity into action,—and that economy in the public expenditure, so conducive to the accumulation of national wealth,—are not the exclusive attributes of any particular species of government. If free states have generally made the most rapid advances in wealth and population, it is an indirect rather than a direct consequence of their political constitution. It results more from the greater security which a popular government presents, that the right of property will be held sacred,—that the freedom of industry will be less fettered and restricted,—and that the public income will be more judiciously levied and expended,—than from the circumstance of a greater proportion of the people being permitted to exercise political rights and privileges. Give the same securities to the subjects of an absolute monarch, and they will make the same advances.

---

[1] It is of importance to observe, that Dr Smith does not say that, in prosecuting such branches of industry as are most advantageous to themselves, individuals necessarily prosecute such as are at the same time *most* advantageous to the public. His leaning to the system of the Economists—a leaning perceptible in every part of his work—made him so far swerve from the principles of his own system as to admit, that individual advantage is not always a true test of the public advantageousness of different employments. He considered that agriculture, though not the only productive employment, is the most productive of any; that the home trade is more productive than a direct foreign trade; and the latter than the carrying trade. It will be hereafter seen that there is no foundation for these distinctions.

[2] Mr Buckle carries his admiration of Smith and his great work to what will perhaps appear to some an extravagant extent. "Well may it be said of Adam Smith, and said, too, without fear of contradiction, that this solitary Scotchman has, by the publication of one single work, contributed more towards the happiness of man than has been effected by the united abilities of all the statesmen and legislators of whom history has preserved an authentic account." (*History of Civilization*, i., p. 196, 2d ed.)

Industry does not require to be stimulated by extrinsic advantages. The additional comforts and enjoyments which it procures have always been found sufficient to insure the most persevering and successful exertions. And whatever may be the form of government, those countries always advance in the career of improvement in which the public burdens are moderate, industry free, and every individual permitted peaceably to enjoy the fruits of his labour. It is not, therefore, so much on its political organization, as on the talents and spirit of its rulers, that the wealth of a country is principally dependent. Economy, intelligence, and liberality on the part of those in power, have frequently elevated absolute monarchies to a very high degree of opulence and prosperity; while all the advantages derived from a more liberal system of government have not been able to preserve free states from being impoverished and exhausted by the extravagance, intolerance, and short-sighted policy of their rulers.

Politics and political economy are therefore sufficiently distinct. The politician examines the principles on which government is founded, he endeavours to determine in whose hands the supreme authority may be most advantageously placed, and unfolds the reciprocal duties and obligations of the governing and governed portions of society. The political economist does not take so high a flight. It is not of the constitution of the government, but of its ACTS only, that he presumes to judge. Whatever measures affect the production or distribution of wealth come within the scope of his observation, and are canvassed by him. He examines whether they are in unison with the principles of the science. If they are, he pronounces them to be advantageous, and shows the nature and extent of the benefits of which they will be productive; if they are not, he shows in what respect they are defective, and to what extent their operation will be injurious. But he does this without inquiring into the constitution of the government by which these measures have been adopted. The circumstance of their having emanated from the privy council of an arbitrary monarch, or the representative assembly of a free state, though in other respects of supreme importance, cannot affect the immutable principles by which he is to form his opinion upon them.

Distinction between statistics and political economy.

Besides being confounded with politics, the practical part of political economy has also been frequently confounded with statistics; but they are still more easily separated and distinguished. The object of the statistician is to describe the condition of a country at a particular period; while the object of the political economist is to discover the causes which have brought it into that condition, and the means by which its wealth and riches may be indefinitely increased. He is to the statistician what the physical astronomer is to the observer. He takes the facts furnished by the statistician, and after comparing them with those furnished by historians and travellers, he applies himself to discover their relation. By a patient induction,—by carefully observing the circumstances attending the operation of particular principles,—he discovers the effects of which they are really productive, and how far they are liable to be modified by the operation of other principles. It is thus that the relation between rent and profit, between profit and wages, and the various general laws which regulate and connect the apparently conflicting, but really harmonious interests of the different classes, have been discovered and established with all the certainty of demonstrative evidence.

PART II.

PRODUCTION OF WEALTH.

SECT. I.—*Definition of Production.—Labour the only Source of Wealth.*

Definition of production.

All the operations of nature and art are reducible to, and really consist of, transmutations,—changes of form and of place. By production in this science is not meant the production of matter, that being an attribute of Omnipotence, but the production of utility, and consequently of exchangeable value, by appropriating and modifying matter, so as to make it satisfy our wants, and contribute to our well-being. The labour which is thus employed is the only source of wealth.[1] Nature spontaneously furnishes the matter of which commodities are made; but, independently of labour, matter is seldom of much use, and is never of any value. Place us on the banks of a river, or in an orchard, and we shall infallibly perish of thirst or hunger, unless, by an effort of industry, we raise the water to our lips, or pluck the fruit from its parent tree. It is seldom, however, that the mere appropriation of matter is sufficient. In the infinite majority of cases, additional labour is required to convey it from place to place, and to give it that peculiar shape, without which it may be totally useless, and incapable of either ministering to our necessities or comforts. The coal used in our fires is buried deep in the bowels of the earth, and is absolutely worthless until the miner has extracted it from the mine, and brought it into a situation where it may be used. The stones and mortar of which our houses are built, and the rugged and shapeless materials from which the various articles of convenience and ornament with which they are furnished have been prepared, were, in their original state, alike destitute of value and utility. And of the innumerable variety of animal, vegetable, and mineral products which form the materials of our food and clothes, few were originally serviceable, while many were extremely noxious to man. His labour has given them utility, has subdued their bad qualities, and made them satisfy his wants, and minister to his comforts and enjoyments. "Labour was the first price, the original purchase money, that was paid for all things. It was not by gold or by silver, but by labour, that all the wealth of the world was originally purchased." (*Wealth of Nations*, p. 14.)

Those who observe the progress and trace the history of the human race in different countries and periods, will find that their well-being has always been pretty nearly proportioned to their expertness in appropriating the raw products of nature, and in adapting them to their use. The savage, who gathers wild fruits, or picks up shellfish on the sea-coast, is placed at the very bottom of the scale of civilization, and is, in point of comfort, decidedly inferior to many of the lower animals. The *first* step in the progress of society is made when man learns to hunt wild animals, to feed himself with their flesh, and clothe himself with their skins. But labour, when confined to the chase, is extremely barren and unproductive. Tribes of hunters, like beasts of prey, whom they closely resemble in their habits and modes of subsistence, are but thinly scattered over the surface of the countries which they occupy; and, notwithstanding the fewness of their numbers, any unusual deficiency in the supply of game never fails to reduce them to the extremity of want. The *second* step in the progress upwards is made when the tribes of hunters and fishers addict themselves, like the ancient Scythians and modern Tartars, to the domestication of wild animals and the rearing of flocks. Their subsistence is much less precarious than that of hunters; but they are almost entirely destitute of the comforts and elegances which give to civilized life its chief value. The *third* and most decisive step in the progress of civilization—in the great art of producing necessaries and conveniences—is made when the wandering tribes of hunters and shepherds renounce their migratory habits, and become agriculturists and manufacturers. It is then, properly speaking, that man begins fully to avail himself of his productive powers. He becomes laborious, and, by a necessary consequence, his wants are for the first time fully supplied, and he acquires an extensive command over the articles required for his comfort as well as subsistence.

---

[1] This point has been well stated by M. Destutt Tracy:—" Non seulement," says he, " nous ne créons jamais rien, mais il nous est même impossible de concevoir ce que c'est que créer ou anéantir, si nous entendons rigoureusement par ces mots, faire quelque chose de rien, ou reduire quelque chose à rien; car nous n'avons jamais vu un être quelconque sortir du néant ni y rentrer. De là cet axiome admis par toute l'antiquité, 'Rien ne vient de rien, et ne peut rédévenir rien.' Que faisons-nous donc par notre travail, par notre action sur tous les êtres qui nous entourent? Jamais rien qu'opérer dans ces êtres des changements de forme ou de lieu qui les approprient à notre usage, qui les rendent utiles à la satisfaction de nos besoins. Voilà ce que nous devons entendre par produire; c'est donner aux choses une utilité qu'elles n'avoient pas. Quel que soit notre travail, s'il n'en resulte point d'utilité, il est infructeux; s'il en resulte, il est productif." (*Traité d'Economie Politique*, p. 162.)

The earth not a source of wealth.

However paradoxical the assertion may at first sight appear, it is notwithstanding true that the earth does not gratuitously supply us with a single atom of wealth. It is a powerful machine given by Providence to man; but without his labour it would be altogether useless, and would stand idle and unemployed. It is through the intervention of labour that the products of the earth become valuable and useful. Its surface is, in its natural state, covered with fruits and game; its bowels contain an infinite variety of mineral products; its seas and rivers are stored with fish; and it is endowed with inexhaustible vegetative and productive powers. But these powers and products are of no use, and have no value, until man renders the former subservient to his purpose, and appropriates the latter, and gives them the peculiar form required to fit them for his service.

Opinion of Hobbes.

The importance of labour in the production of wealth was very clearly perceived both by Hobbes and Locke. At the commencement of the 24th chapter (entitled, "Of the Nutrition and Procreation of a Commonwealth") of the *Leviathan*, published in 1651, Hobbes says, "The nutrition of a commonwealth consisteth in the plenty and distribution of materials conducing to life.

"As for the plenty of matter, it is a thing limited by nature to those commodities which, from (the two breasts of our common mother) land and sea, God usually either freely giveth, or for labour selleth to mankind.

"For the matter of this nutriment, consisting in animals, vegetables, minerals, God hath freely laid them before us, in or near to the face of the earth, so as there needeth no more but the labour and industry of receiving them: insomuch that plenty dependeth (next to God's favour) on the labour and industry of man."

Opinion of Locke.

But Locke had a much clearer apprehension of this doctrine. In his *Essay on Civil Government*, published in 1689, he has entered into a lengthened and able analysis to show that the products of the earth owe almost all their value to labour. "Let any one consider," says he, "what the difference is between an acre of land planted with tobacco or sugar, sown with wheat or barley, and an acre of the same land lying in common, without any husbandry upon it, and he will find that the improvement of labour makes the far greater part of the value. I think it will be but a very modest computation to say that, of the products of the earth useful to the life of man, *nine-tenths* are the effects of labour; nay, if we will rightly consider things as they come to our use, and cast up the several expenses about them, what in them is purely owing to nature and what to labour, we shall find that in most of them *ninety-nine hundredths* are wholly to be put on the account of labour.

"There cannot be a clearer demonstration of anything than several nations of the Americans are of this, who are rich in land and poor in all the comforts of life; whom nature, having furnished as liberally as any other people with the materials of plenty,—*i. e.*, a fruitful soil apt to produce in abundance what might serve for food, raiment, and delight,—yet, for want of improving it by labour, have not one-hundredth part of the conveniences we enjoy; and the king of a large and fruitful territory there feeds, lodges and is worse clad, than a day-labourer in England.

"To make this a little clear, let us but trace some of the ordinary provisions of life through their several progresses before they come to our use, and see how much of their value they receive from human industry. Bread, wine, and cloth are things of daily use and great plenty; yet notwithstanding, acorns, water, and leaves or skins must be our bread, drink, and clothing, did not labour furnish us with these more useful commodities; for whatever bread is more worth than acorns, wine than water, and cloth or silk than leaves, skins, or moss, that is solely owing to labour and industry; the one of these being the food and raiment which unassisted nature furnishes us with, the other provisions which our industry and pains prepare for us, which how much they exceed the other in value, when any one hath computed, he will then see how much labour makes the far greatest part of the value of things we enjoy in this world; and the ground which produces the materials is scarce to be reckoned on as any, or at most but a very small part of it.

"An acre of land that bears here twenty bushels of wheat, and another in America which, with the same husbandry, would do the like, are without doubt of the same natural intrinsic value. But yet the benefit mankind receives from the one in a year is worth L.5, and from the other possibly not worth *one penny*; if all the profit an Indian received from it were to be valued and sold here, at least, I may truly say, not $\frac{1}{1000}$th. 'Tis labour, then, which puts the greatest part of value upon land, *without which it would scarcely be worth anything*; 'tis to that we owe the greatest part of its useful products; for all that the straw, bran, bread, of that acre of wheat is more worth than the product of an acre of good land which lies waste, is all the effect of labour. For 'tis not merely the ploughman's pains, the reaper's and thrasher's toil, and the baker's sweat, is to be counted into the bread we eat; the labour of those who broke the oxen, who digged and wrought the iron and stones, who felled and framed the timber employed about the plough, mill, oven, or any other utensils, which are a vast number, requisite to this corn, from its being seed to be sown to its being made bread, must all be charged on the account of *labour*, and received as an effect of that; Nature and the earth furnishing only the almost worthless materials as in themselves. 'Twould be a strange catalogue of things that industry provided and made use of about every loaf of bread, before it came to our use, if we could trace them. Iron, wood, leather, barks, timber, stone, brick, coals, lime, cloth, dyeing drugs, pitch, tar, masts, ropes, and all the materials made use of in the ship that brought away the commodities made use of by any of the workmen, to any part of the work; all which it would be almost impossible, at least too long, to reckon up." (*Of Civil Government*, book ii., §§ 40, 41, 42, and 43.)[1]

Had Locke carried his analysis a little further, he could not have failed to perceive that water, leaves, skins, and the other spontaneous productions of nature, have no value except what they owe to the labour required for their appropriation. The value of water to a man placed on the bank of a river depends on the labour required to raise it to his lips; and its value, when carried ten or twenty miles off, is equally dependent on the labour required to convey it there. All the rude products and capacities of nature are gratuitously offered to man. She is not niggardly or parsimonious. She neither demands nor receives an equivalent for her favours. An object or a power which may be freely appropriated or applied to our use, may, like the water which floats a ship, or the wind which fills her sails, be of the very highest utility; but being the free gift of nature, it has no value.[1]

---

[1] This is a very remarkable passage. It contains a far more distinct and comprehensive statement of the fundamental doctrine, that labour is the constituent principle of value, than is to be found in any other writer previous to Smith, or than is to be found even in the

"Si je retranche," to use a striking illustration of this doctrine given by M. Canard, "de ma montre, par la pensée, tous les travaux qui lui ont été successivement appliquées, il ne resterai que quelques grains de minéral placées dans l'intérieur de la terre, d'où on les a tirés, et où ils n'ont aucune valeur. De même, si je décompose le pain que je mange, et que j'en retranche successivement tous les travaux successifs qu'il a reçus, il ne restera que quelques tiges d'herbes, graminées, éparses dans des désertes inculcates, et sans aucune valeur." (*Principes d'Economie Politique*, p. 6.)

It has been said that demand is the source or cause of value. Such, however, is not the case. The real or supposed suitableness of certain articles to satisfy our wants, or to add to our enjoyments, makes them, as already seen, objects of desire or demand. But their value depends entirely on the greater or less difficulty of obtaining them, that is, on the greater or less quantity of labour required to produce or acquire them. This labour, therefore, is at once the source and the measure of their value.

But suppose that we stumble upon a nugget of gold or a diamond, are we to be told, it is asked, that its value is proportioned only to the labour, if so it may be called, expended in finding it? No! you are to be told nothing of the sort. In these and all similar inquiries, the question does not turn upon accidental or exceptional occurrences, like that now referred to, but upon the nature of the processes necessary to obtain sufficient supplies of the required article. If gold and diamonds could be had in any quantity in the easy way that has been specified, their value would sink accordingly, and they would become cheaper than iron or bits of glass. But not one millionth—no, nor one ten-millionth—part of the supplies of gold and diamonds brought to market has ever been, or ever will be, furnished by chance finders. And the quantities offered by them being so extremely small as to have no influence of any kind upon the market, they are sold at the price necessary to indemnify the ordinary producers of the metal and the gem. And hence, though it may not be strictly true of every sovereign in existence, or of every diamond, hat, or other article in the shops, that its price is proportioned to the cost of its production, this (apart from general fluctuations) is true in more than 999 out of every 1000 instances. Those that are exceptions are so very few as to be wholly inappreciable and undeserving of any notice.

It is to labour, therefore, that we owe everything possessed of exchangeable value. *Dii laboribus omnia vendunt.* Labour is the talisman that has raised man from the condition of the savage—that has changed the desert and the forest into cultivated fields—that has covered the earth with cities and the ocean with ships—that has given him plenty, comfort, and elegance, instead of want, misery, and barbarism.

"Why," asks Dr Barrow, "is any man a beggar, why contemptible, why ignorant, why vicious, why miserable? Why, but for this one reason, because he is slothful; because he will not labour to rid himself of these evils?" (Second Sermon on Industry.)

Having established this fundamental principle—having shown that labour alone gives value to commodities and procures for us whatever we most covet and desire—it is plain that the great practical problem of this science must resolve itself into a discussion of the means by which labour may be rendered most efficient, that is, by which the greatest amount of necessary and desirable products may be obtained with the least outlay of labour. Every measure and invention that has any tendency to save labour, or to reduce the cost of commodities, adds proportionally to our command over wealth and riches; while every measure or regulation that has any tendency to waste or misapply labour, or to raise the cost of commodities, equally lessens this command. This is the simple and decisive test by which we are to judge of every measure affecting the wealth of the country, and of every invention. If they render labour more productive—if they tend to reduce the value of commodities—to render them more easily obtainable, and consequently to bring them within the command of a greater portion of society—they are advantageous; but if their tendency be different, they are as certainly disadvantageous. Considered in this point of view, that great branch of the science which treats of the production of wealth will be found to be abundantly simple, and easily understood.

Labour, according as it is applied to the raising of raw produce—to the fashioning of that raw produce, when raised, into articles of utility, convenience, or ornament—and to the conveyance of raw and wrought products from one country and place to another—is said to be agricultural, manufacturing, and commercial. An acquaintance with the particular processes and most advantageous methods of applying labour in each of these great departments of industry, forms the appropriate study of the agriculturist, manufacturer, and merchant. It is not consistent with his objects for the political economist to enter into the details of particular businesses and professions. He confines himself to an investigation of the means by which labour gene-

---

Wealth of Nations. But Locke does not seem to have been sufficiently aware of the value of the principle he had elucidated, and has not deduced from it any important practical conclusion. On the contrary, in his tract on the *Raising of the Value of Money*, published in 1691, he lays it down broadly, that all taxes, however imposed, ultimately *fall on the land;* whereas it is plain he should, consistently with the above principle, have shown that they would fall, not exclusively on the produce of land, but generally on the produce of industry, or on all species of commodities.

[1] Bishop Berkeley entertained very just opinions respecting the source of wealth. In his *Querist*, published in 1735, he asks,—"Whether it were not wrong to suppose *land* itself to be wealth? And whether the *industry of the people* is not first to be considered as that which constitutes wealth, which makes even land and silver to be wealth, neither of which would have any value but as means and motives to industry?" "Whether, in the wastes of America, a man might not possess twenty miles square of land, and yet want his dinner or a coat to his back." (*Querist*, Nos. 38 and 39.) We shall afterwards notice Sir William Petty's opinion on this subject. Say appears to think (*Discours Préliminaire*, p. 37) that Galiani was the first to show, in his treatise *Della Moneta*, published in 1750, that labour is the only source of wealth. But the passages we have now laid before the reader prove the erroneousness of this opinion. Galiani has entered into no analysis or argument to prove the correctness of his statement; and as it appears from other parts of his work that he was well acquainted with Locke's *Tracts on Money*, a suspicion naturally arises that he had seen the *Essay on Civil Government*, and that he was really indebted to it for a knowledge of this principle. This suspicion derives strength from the circumstance of Galiani being still less aware than Mr Locke of the value of the discovery. (See *Trattato della Moneta*, p. 39, ediz. 1780.)

rally may be rendered most productive, and how its powers may be increased in *all* departments of industry.

SECT. II.—*Means by which the Productive Powers of Labour are Increased.—Security of Property.—Division of Labour.—Accumulation and Employment of Capital.*

Means by which the productive powers of labour may be increased.

The most careless and inattentive observer of the progress of mankind from poverty to affluence must have early perceived that there are *three* circumstances whose conjoint operation is necessary to stimulate and improve the productive powers of industry. The *first* and most indispensable is that *security of property*, which produces a strong conviction in the mind of individuals that they will be allowed to dispose at pleasure of the fruits of their industry. The *second* is the introduction of exchange or barter, and the consequent appropriation of particular individuals to particular employments. And the *third* is the accumulation and employment of the produce of previous labour, or, as it is more commonly termed, of capital or stock. Every improvement that either has been or that may yet be made in the production of necessaries and conveniences, will be found to be resolvable into the more judicious application of one or more of those means of stimulating labour, and adding to its power. To give a full exposition of the nature and influence of each would far exceed the limits of this article; and we must content ourselves with such observations as may suffice to give a general idea of their operation.

Security of property.

Security of property is the first and most indispensable requisite to the production of wealth. Its utility in this respect is so obvious, as to make it be more or less respected in every country, and in the earliest and rudest periods. All have been impressed with the reasonableness of the maxim which teaches that those who sow should be permitted to reap; that the labour of a man's body and the work of his hands should be considered as exclusively his own. No horde, how barbarous soever, has been discovered in which the principle of *meum* and *tuum* was not recognised. Nothing, it is evident, could ever tempt any one to engage in laborious employments—he would neither domesticate wild animals, nor clear and cultivate the ground,—if, after months and years of toil, when his flocks had become numerous, and his harvests were ripening for the sickle, a stranger were allowed to rob him of the produce of his industry. No wonder, therefore, that the utility of regulations fitted to secure to individuals the peaceable enjoyment of the produce they had raised, and of the ground they had cultivated and improved, suggested itself to the first legislators. The author of the book of Job places those who removed their neighbours' landmarks at the head of his list of wicked men; and some of the earliest profane legislators subjected those guilty of this offence to a capital punishment. (Goguet, *De l'Origine des Loix*, &c., tom. i., p. 30, 4to ed.)

Paley has said that the law of the land is the real foundation of the right of property. But the obvious utility of securing to individuals the property acquired by their industry has undoubtedly formed the irresistible reason which has induced every people emerging from barbarism to establish this right. It is, in truth, the foundation on which all the institutions of society rest. Until property has been publicly guaranteed, men look on each other as enemies rather than as friends. The idle and improvident are always desirous of seizing on the earnings of the laborious and frugal; and were their efforts to enrich themselves by the plunder of their neighbours not restrained by the strong arm of the law, they would, by generating a feeling of insecurity, effectually check both industry and accumulation, and sink all classes to the same level of hopeless misery as themselves. Nor is the security of property less necessary to accumulation than to production. No man ever denies himself an immediate gratification when it is within his power, unless he think that by doing so he has a fair prospect of obtaining at some future period a greater accession of comforts and enjoyments, or of avoiding some considerable evil. Where the right of property is vigilantly protected, an industrious man, who produces as much by one day's labour as is sufficient to maintain him two days, instead of idling away the second day, accumulates the surplus which exceeds his wants as a capital; the increased consequence and enjoyments which the possession of capital brings along with it being, in the great majority of cases, more than sufficient to countervail the desire of immediate gratification. But wherever property is insecure, we look in vain for the operation of this principle. "It is plainly better for us," is then the invariable language of the people, "to enjoy while it is in our power, than to accumulate property which we shall not be permitted to use, and which will either expose us to the extortion of a rapacious government, or to the depredations of those who exist only by the plunder of their more industrious neighbours."

The right of property is not violated merely when a man is deprived of the power of peaceably enjoying the fruits of his industry; it is also violated, and perhaps in a still more unjustifiable manner, when he is prevented from exerting himself in any way not injurious to others that he considers most likely to conduce to his interests. Of all the species of property which a man can possess, the faculties of his mind and the powers of his body are most particularly his own. He should therefore be permitted to enjoy, that is, to use or exert these powers at discretion. And hence the right of property is as much or more infringed upon when a man is interdicted from engaging in such and such branches of business, as it is when the property he has produced and accumulated is forcibly taken from him. Every monopoly which gives to a few individuals the power to carry on certain branches of industry to the exclusion of others, is thus, in fact, established in direct violation of the rights of every one else. It prevents them from using their natural capacities or powers in the way they might consider best; and as every man who is not a slave is justly held to be the best judge of what is advantageous for himself, the principles of natural law and the right of property are both subverted when he is excluded from any lawful business. In like manner, the right of property is violated whenever individuals are obliged to employ themselves or their property in any specified manner, to accept certain rates of interest for loans, or certain rates of wages, and so forth.

Effects of insecurity.

The finest soil, the finest climate, and the finest intellectual powers can prevent no people from becoming barbarous, poor, and miserable, if they have the misfortune to be subjected to a government which does not respect and support the right of property. This is the greatest of all calamities. The ravages of civil war, of pestilence, and of famine may be repaired, but nothing can enable a nation to contend against the deadly influence of an established system of violence and rapine. The want of security, of a lively and well-founded expectation of being permitted freely to dispose of the fruits of industry, is the principal cause of the wretched state of the Ottoman dominions in the present day, as it was of the decline of industry and arts in Europe during the middle ages. When the Turkish conquerors overran those fertile and beautiful countries in which, to the disgrace of the other European powers, they are still permitted to encamp, they parcelled them among their followers, on condition of their performing certain military services, on a plan corresponding in many important particulars to the feudal system of our ancestors. But these possessions are not hereditary. And unless their present possessors leave them in trust to some religious incorporation for behoof of their children and legatees, they would, on their death, revert to the sultan. Hence, among the greater number of the occupiers of land in Turkey there is little thought of futurity. No one feels any interest about the prosperity of an unknown successor, and, except in the peculiar cases now mentioned, no one ever executes any improvement unless he expects to reap all the advantage during his own life. This is the cause why the Turks are so extremely careless about their houses. They seldom construct them of solid or durable materials. And it would be a gratification were they assured that they would fall to pieces the moment they have breathed their last. Under this miserable system the palaces have been changed into cottages, and the cities into villages. The long-continued want of security has extinguished the very spirit of industry, and destroyed not only the power, but even the desire to emerge from barbarism.

Had it been possible for arbitrary power to profit by the lessons of experience, it would long since have perceived that its own wealth, as well as that of its subjects, would be best promoted by maintaining the inviolability of property. Were the Turkish government to establish a vigilant system of police, to give to individuals full power to dispose of the fruits of their labour, and to substitute a regular plan of taxation for the present odious system of extortion and tyranny, industry would revive, capital and population would be augmented, and moderate duties, imposed on a few articles in general demand, would bring a much larger sum into the coffers of the treasury than all that is now obtained by force and violence. The stated public burdens to which the Turks are subject are light compared with those imposed on the English, the Hollanders, and the French. But when the latter have paid the taxes due to government, they know they will be permitted peaceably to enjoy or accumulate the remainder of their earnings; whereas the Turk, notwithstanding the reforms of which so much has been said, has no security but that, the moment after he has paid his stated contribution, the pasha, or one of his satellites, may strip him of every additional farthing he possesses. Security is the foundation, the principal element, in every well-digested system of finance. When maintained inviolate, it enables countries to support with little difficulty a very heavy load of taxes; but where there is no security, where property is a prey to rapine and spoliation, to the attacks of the needy, the powerful, or the profligate, the smallest burdens are justly regarded as oppressive, and uniformly exceed the means of the impoverished and spiritless inhabitants.

Let us not, therefore, deceive ourselves by supposing that it is possible for any people to emerge from barbarism, or to become wealthy, populous, and civilized, without the security of property. From whatever point of the political compass we may set out, this is the principle to which we must come at last. Security is indispensable to the successful exertion of the powers of industry. Where it is wanting, it is idle to expect either riches or civilization.[1] "The exclusive right to the produce is the only excitement to industry which acts constantly and universally—the only spring which keeps human labour in motion."[2]

Objection of Rousseau and Beccaria ill-found

Rousseau and some other writers of his caste have made an objection to the right of property, which has been in some measure sanctioned by Beccaria.[3] They allow that this right is advantageous for those who possess property; but they contend that it is disadvantageous for those who are poor and destitute. It condemns, say they, the greater portion of mankind to a state of misery, and provides for the exaltation of the few by the depression of the many! The sophistry of this reasoning is so apparent as hardly to require being pointed out. The right of property has not made poverty, but it has made wealth. Previously to its institution, those nations which are now most civilized were sunk to the same level of wretchedness and misery as the savages of New Holland and Kamtschatka. All classes have been benefited by the change, and it is mere error and delusion to suppose that the rich have been benefited at the expense of the poor. The right of property gives no advantage to any one man over any other man. It deals out justice impartially to all. It does not say, "Labour, and I shall reward you," but it says, "Labour, and I shall take care that none be permitted to rob you of the produce of your exertions." This right has not made all men rich, because it could not make all men frugal, fortunate, and industrious. But it has done more than all the other institutions of society put together to produce that result. It is not, as it has been sometimes ignorantly or knavishly represented, a bulwark thrown up to protect the property of a few favourites of fortune. It is a rampart raised by society against its common enemies,—against rapine and violence, plunder and oppression. Without its protection, the rich man would become poor, and the poor man would never be able to become rich,—all would sink to the same bottomless abyss of barbarism and poverty. "The security of property has overcome the natural aversion of man from labour, given him the empire of the earth, a fixed and permanent residence, and has implanted in his breast the love of country and of posterity. To enjoy immediately,—to enjoy without labour,—is the natural inclination of every man. This inclination must be restrained; for its obvious tendency is to arm all who have nothing against those who have something. The law which restrains this inclination, and which secures to the humblest individual the quiet enjoyment of the fruits of his industry, is the most splendid achievement of legislative wisdom,—the noblest triumph of which humanity has to boast." (Bentham, *Traité de Législation*, tom. ii., p. 37.)[4]

Division of labour

Division of Labour.—The division of labour may be best treated of in two branches,—viz., 1*st*, The division of labour among individuals; and, 2*d*, Its division among nations.

---

[1] "Ce n'est que là où les proprietés sont assurés, où l'emploi des capitaux est abandonné au choix de ceux qui les possédent; ce n'est que là, dis-je, que les particuliers seront encouragés à se soumettre aux privations le plus dures pour compenser par leurs épargnes les retards que la profusion du gouvernement peut apporter aux progrès de la richesse national. Si l'Angleterre, malgré ses guerres ruineuses, est parvenue à un haut degré d'opulence; si, malgré les contributions énormes dont le peuple y est chargé, son capital est pourtant accrue dans le silence par l'économie des particuliers, il ne faut attribuer ces effets qu'à la liberté des personnes, et à la sureté des proprietés qui y règnent, plus que dans aucun autre pays de l'Europe, la Suisse excepté." (Storch, *Traité d'Economie Politique*, tom. i., p. 317.)

[2] Paley's *Moral Philosophy*, b. vi., cap. 11.

[3] Speaking of theft, Beccaria calls it "Il delitto di quella infelice parte di uomini a cui *il diritto di proprietà* (*terribile, e forse non necessario diritto*), *non ha lasciato che una nuda essistenza.*" (*Dei Delitti e delle Pene*, § 22.)

[4] The treatise of M. Thiers, *De la Propriété*, is deserving of the highest commendation. It was published in 1848, when Communism was struggling for the ascendant, and the maxim *la propriété c'est le vol* was current in France. Thiers has set in the clearest light the folly, and indeed, atrocity of the projects involved in the schemes of the Communists, and in the principles, if so we may call the miserable fallacies, on which they were said to be bottomed; and has forcibly depicted the universal poverty and barbarism that would inevitably follow from their being adopted. It says little for the progress of science, or for the influence of common-sense, that such pernicious theories should have received any popular support. It is satisfactory, however, to find that, when put forth, their real character and tendency was so promptly and ably exposed.

1. *Individual Division of Labour.*—The division of labour can only be imperfectly introduced in rude societies and thinly-peopled countries. But in every state of society, in the rudest as well as in the most improved, we may trace its operation and effects. Men are endowed with such various physical powers, talents, and propensities, that those who are best fitted for some pursuits, are not unfrequently wholly unfit for others. These differences being palpable and obvious, a regard to their mutual interest and convenience would lead them, at a very early period, to introduce the practice of barter and a subdivision of employments. And a brief experience would suffice to show, not only that their tasks were in consequence better suited to their capacities, but that their aggregate production was largely increased; and that to obtain the greatest supply of useful and desirable articles, they should apply themselves to particular businesses, and exchange the articles each had to spare for such of the products of his neighbours as he had occasion for, and they were willing to part with. As society advances, this system becomes more and more extended. In process of time different men become tanners or dressers of skins, shoemakers, weavers, house-carpenters, smiths, and so on; and each endeavours to cultivate and bring to perfection whatever talent or genius he may possess for the peculiar branch of industry in which he is employed. The mass of necessary and desirable articles and services is in consequence prodigiously augmented. Wherever the division of labour is carried to any considerable extent, agriculturists do not spend their time in clumsy attempts to manufacture their own produce; and manufacturers cease to interest themselves about the raising of corn and the fattening of cattle. The facility of exchanging is the vivifying principle of industry. It stimulates agriculturists to adopt the best system of cultivation, and to raise the largest crops, that they may barter such portions of their produce as exceed their wants for the various articles furnished by manufacturers and merchants; and it stimulates the latter to put forth their energies in the view of obtaining greater quantities of agricultural and other raw products. Hence it is that the business of an advanced society resolves itself almost entirely into the negotiation of exchanges; and that society itself may be said to be an association founded on a principle of reciprocity, in which, speaking generally, nothing is to be had except for an equivalent of one sort or other.[1]

The advantages that result from individuals being able to embrace the pursuits which are most agreeable to their tastes, and for which they are best suited, are too apparent to require further notice. But the influence of the division of employments in adding to the efficiency of labour, though less obvious than the other, is no less important, and requires to be set in its true light. This has been done in a very masterly manner by Smith, who has classed the circumstances which make the division of labour increase its productive powers under the following heads:—*First,* The increase of the skill and dexterity of the workman; *Second,* The saving of time, which would otherwise be lost in passing from one employment to another; and, *Third,* The tendency of the division of employments to facilitate the invention of machines and processes for abridging and saving labour. We shall make a few observations on each of these heads.

D ision of la ur in cr ses the sk and de erity of w kmen.

1*st, As respects the increased skill and dexterity of the labourer*, it is plain that when a person's whole attention is devoted to some one calling, when all the energies of his mind and powers of his body are made to bear, as it were, on it only, he can hardly fail to attain to a degree of proficiency in that calling to which no individual engaged in a variety of occupations can be expected to reach. A peculiar play of the muscles, or sleight-of-hand, is necessary to perform the simplest operation in the best and most expeditious manner; and this can only be acquired by constant practice. Smith has given an example, in the case of the nail manufacturer, of the extreme difference between training a workman to the precise occupation in which he is to be employed, and training him to a similar and closely allied occupation. "A common smith," says he, "who, though accustomed to handle the hammer, has never been used to make nails, if, upon some particular occasion, he is obliged to attempt it, will scarce, I am assured, be able to make above two or three hundred nails in a day, and those very bad ones. A smith who has been accustomed to make nails, but whose sole or principal business has not been that of a nailer, can seldom, with his utmost diligence, make more than eight hundred or a thousand nails in a day. But I have seen several boys under twenty years of age, who had never exercised any other trade but that of making nails, who, when they exerted themselves, could make each of them upwards of *two thousand three hundred nails in a day;*" or nearly three times the number of the smith who had been accustomed to make them, but who was not entirely devoted to that particular business!

Saves time.

2*d,* The division of labour prevents that *waste of time in moving from one employment to another* which necessarily takes place when the same individuals have successively to engage in different occupations. If these be carried on at considerable distances from each other, and require, as they generally do, different sets of tools, the serious loss of time that is occasioned by leaving one and going to another is obvious. And though the employments were contiguous, or concentrated in the same workshop, the loss would be very considerable. For, as Smith has observed, "a man commonly saunters a little in changing from one business to another. When he first begins his work, he is seldom keen or hearty; his mind is said not to go along with it, and for some time he rather trifles than applies himself to good purpose. The habit of sauntering, and of indolent, careless application, which is naturally, or rather necessarily, acquired by every country workman, who is obliged to change his work and his tools every half hour, and to apply his hand in twenty different ways almost every day of his life, renders him almost always slothful and lazy, and incapable of any vigorous application, even on the most pressing occasions. Independent, therefore, of his deficiency in point of dexterity, this cause alone must always reduce considerably the quantity of work which he is capable of performing." (*Wealth of Nations*, p. 5.)

Facilitates the invention of machines.

3*d,* As respects the tendency of the division of employments to *facilitate the invention of machines and processes for saving labour*, it is obvious that those engaged in an industrial pursuit will be more likely to discover easier and readier methods of carrying it on when their attention is devoted exclusively to it, than if they had occasionally to attend to a number of other pursuits. But it is a mistake to suppose, as is sometimes done, that the influence of the division of labour is confined to work-people and artificers. It extends to all classes,—to those who work with the head as well as those who work with the hand. As society advances, the study of particular branches of science and philosophy becomes the principal or sole occupation of the most ingenious men. Chemistry becomes a distinct science from natural philosophy; the physical astronomer separates himself from the astronomical observer; the political economist from the politician; and each meditating exclusively or principally on his peculiar department, attains to a degree of proficiency and expertness in it which the general scholar seldom or never reaches. And hence, in labouring to promote our own ends, we adopt those courses which are most advantageous for all. Like the different parts of a well-constructed engine, the inhabitants of countries like England are all mutually dependent on and connected with each other. Without any previous concert, and obeying only the powerful and steady impulse of self-interest, they universally conspire to the same great end, and contribute, each in his respective sphere, to furnish the greatest supply of necessaries, conveniences, and enjoyments.

---

[1] "Je ne crains point le dire: la société *est purement et uniquement une série continuelle d'échanges;* elle n'est jamais autre chose dans aucune époque de sa durée, depuis son commencement le plus informe jusqu'à sa plus grande perfection; et c'est là le plus grand éloge qu'on en puisse faire, car l'échange est une transaction admirable, dans laquelle les deux contracteurs gagnent toujours tous deux; par consequent la société est une suite non interrompue d'avantages sans cesse renaissans pour tous ses membres." (Destutt Tracy, *Economie Politique*, p. 144.)

Division of labour limited by the extent of the market.

But it should be observed that the advantages derived from the division of labour, though they are partially enjoyed in every country and state of society, are only reaped in their full extent where there is a great power of exchanging, or an extensive market. Many employments cannot be separately carried on beyond the precincts of a large city; and in all cases the division becomes more perfect according as the demand for the produce of the work is extended. It is stated by Smith that in his time ten labourers employed in different departments in a pin factory could produce 48,000 pins a day; and such has been the progress of improvement, that they are now (1858) able to produce twice that number, or upwards. But, unless the demand had been sufficiently extensive to take off this increased quantity, it is evident that the greater division of employments and other improvements introduced into the factory, could not have been carried to their present extent. And this principle holds in every case. A cotton-mill could not be constructed in a small country having no intercourse with its neighbours. The demand and competition of the commercial world have been necessary to carry the manufactures of Glasgow, Manchester, and Birmingham to their present state of improvement.

The influence of the division of labour in multiplying and perfecting the products of industry was noticed by several writers previous to Smith, especially Harris and Turgot. But none of them did what Smith has done. None of them fully analysed and exhibited its various effects, or showed that the power of engaging in different employments depends on the power of exchanging; and that consequently the advantages derived from the division of labour are dependent on, and regulated by, the extent of the market. This is a principle of great importance, by establishing which Smith shed a new light on the theory of production, and laid the foundation of many important practical conclusions. "Présentée de cette manière," says M. Storch, "l'idée de la division du travail étoit absolument neuve; et l'effet qu'elle a fait sur les contemporains de Smith, prouve bien qu'elle l'étoit réellement pour eux. Telle qu'elle se trouve indiquée dans les passages que je viens de citer, elle n'a fait aucune impression. Développée par Smith, cette idée a d'abord saisi tous ses lecteurs; tous en ont senti la vérité et l'importance; et cela suffit pour lui en assurer tout l'honneur, lors même que son génie ait été guidé par les indications de ses devanciers." (Tome vi., p. 10.)

Territorial division of labour.

2. *Territorial Division of Labour, or Commerce.*—The division of labour is not confined to its effect on the occupations of men in limited societies. It extends much further than this; and influences the population of entire provinces, and even great nations, in the same way that it influences individuals and families, by teaching them that it is for their interest to addict themselves in preference to those industrial pursuits for succeeding in which they have some natural or acquired advantage. And hence the *territorial division of employments*, and the commerce of which it is at once the cause and the effect. The various soils, climates, and capacities of the different districts of an extensive country render some particularly well suited for the prosecution of certain branches of industry, and others for the prosecution of other branches. A district where coal is abundant, which has an easy access to the ocean, and a considerable command of internal navigation, is the natural seat of manufactures. Wheat and other species of grain are the proper products of rich arable soils; and cattle, after being reared in mountainous districts, are most advantageously fattened in meadows and low grounds. Nothing is more obvious than that the inhabitants of these districts, by confining themselves to the businesses for the carrying on of which they have some especial capability, will produce a much greater aggregate quantity of useful and desirable articles than they could do were they to engage indiscriminately in every possible employment. It cannot be doubted that a vastly greater supply of manufactured goods, corn, and cattle, is produced by the inhabitants of Glasgow, the Carse of Gowrie, and Argyleshire respectively, confining themselves to manufactures, agriculture, and the rearing of cattle, than if each had endeavoured, in addition to their own, to raise the products peculiar to the others.

But it is easy to see that foreign trade, or the territorial division of labour between different and independent countries, contributes to increase the wealth of each in the same manner that the trade between different provinces of the same kingdom contributes to increase their wealth. There is a still greater difference between the productive powers with which nature has endowed different and distant countries than there is between those of the provinces of the same country. The establishment of a free intercourse between them must therefore be proportionally more advantageous. It would evidently cost a great deal more to raise the wines of France or Spain in England, than to make Yorkshire yield the same products as Devonshire. Indeed there are a multitude of products, some of which are of the very greatest utility, that cannot be raised except in particular situations. Were it not for our commercial intercourse with foreigners, we should be wholly destitute of tea, raw cotton, raw silk, gold bullion, and a thousand other equally useful and valuable commodities. Providence, by giving different soils, climates, and natural productions to different countries, has evidently provided for their mutual intercourse and civilization. There can, indeed, be no reasonable doubt, had their trade been free and unfettered, that each people would have engaged in preference in those departments of industry in which their genius, the capacities of their soil, their products, climate, and situation fitted them to excel. And though, owing to the prevalence of that selfish and short-sighted policy, of which we have traced the outline, the benefits that would have resulted from foreign trade have been greatly diminished, still it would be no easy matter to exaggerate the amount and importance of those of which, even in its restricted state, it has been productive. Products of all sorts have been multiplied and cheapened; and their distribution binds together the universal society of nations by the common and powerful ties of mutual interest and reciprocal obligation. Commerce has also, by showing how greatly they are indebted to others, moderated the extravagantly high opinion which nations, when they have little intercourse with their neighbours, are too apt to entertain of themselves; and has thus either wholly removed or greatly weakened a host of unworthy prejudices. It has shown that nothing can be more illiberal and absurd than the once prevalent dread of the progress of others in wealth and civilization; and that the true glory and real interest of every nation will be more certainly advanced by endeavouring to emulate and outstrip its neighbours in the career of science and civilization, than by labouring to attain a barren pre-eminence in the bloody and destructive, though necessary, art of war.

Effect of the territorial division of labour in augmenting national wealth.

The way in which commerce gives increased efficacy to labour, and augments national wealth, may be easily illustrated. Thus, in the case of the intercourse, or territorial division of labour, carried on between England and Portugal, our superior wool, added to our command of coal, skilful workmen, and improved machinery, enable us to produce cloth at a much cheaper rate than the Portuguese; while, on the other hand, the soil and climate of Portugal being peculiarly favourable for the growth of the grape, she produces wine at an infinitely less cost than it could be produced for here. And hence it is obvious that, by exchanging cloth for wine, and wine for cloth, both parties, the English and Portuguese, are greatly benefited. Each of them is incomparably better supplied than they otherwise would be with useful and desirable articles. Portions of their capital and industry are diverted into those channels in which they are naturally most productive and most secure; and in which, consequently, it is not more for their own than for the general advantage of mankind that they should be employed.

Sophism of the French Economists on the subject of commerce.

These statements are sufficient to expose the sophism of the Economists, who contended that, as equivalents must always be given for commodities brought from abroad, foreign commerce could not be a means of increasing wealth. How, they asked, can wealth be increased by giving equal values for equal values? They admitted that commerce might make a *better distribution* of the wealth of the world; but as it merely exchanged one sort of wealth for another, they denied that it could make any addition to its amount. At first sight, this sophistical and delusive statement appears sufficiently conclusive; but a very few words will be enough to demonstrate its fallacy. In commercial transactions none of the parties obtain articles of greater value than those they gave in exchange for them. The cloth with which the English merchant purchases Portuguese wine may have cost as much as the latter, or it may have cost more. But then it must be observed that, in making the exchange, the value of the wine is estimated by what it takes to produce it in Portugal, which has peculiar capabilities for that species of industry, and not by what it would take to produce it in England were the trade put an end to; and, in like manner, the value of the cloth is estimated by what it takes to produce it in England, and not by what it would take to produce it in Portugal. Hence, by trading together, countries obtain commodities which it might not be possible for them to produce at home, or, if possible, only at a comparatively heavy cost, for what it takes to produce them in other countries under the most favourable circumstances, and at the least expense. The gain of one is not the loss of another. They are universally benefited by the intercourse; for their labour being better distributed and rendered more efficient, they all obtain larger supplies of useful and desirable articles.

To set this important principle in a clearer point of view, let it be supposed that in England a given number of men can, in a given time, manufacture 10,000 yards of cloth and raise 1000 quarters of wheat, and that the same number of men can, in a given time, manufacture in Poland 5000 yards of cloth and raise 2000 quarters of wheat. It is plain that the establishment of a free intercourse between the two countries would in these circumstances enable England, by manufacturing cloth and exporting it to Poland, to obtain *twice* the quantity of corn in exchange for a given outlay of capital and labour that she would obtain in return for the same outlay on cultivation at home; and Poland would, on her part, be enabled to obtain *twice* as much cloth in exchange for her corn as she would have done had she attempted directly to manufacture it. How ridiculous, then, to contend that commerce is not a means of adding to the efficacy of labour, and consequently of increasing wealth! Were the intercourse between England and Portugal and the West Indies put an end to, it would require at least fifty or a hundred times the expense to produce port-wine, sugar, and coffee, directly in this country, that is required to produce the equivalents sent to Portugal and the West Indies in exchange for them. And no outlay, however great, could directly supply us with teas, spices, and fifty other most important articles.

"The commerce of one country with another is merely an extension of that division of labour by which so many benefits are conferred on the human race. As the same country is rendered richer by the trade of one province with another; as its labour becomes thus infinitely more divided and more productive than it could otherwise have been; and as the mutual interchange of all those commodities which one province has and another wants, multiplies the accommodations and comforts of the whole, and the country becomes thus in a wonderful degree more opulent and happy; so the same beautiful train of consequences is observable in the world at large, that vast empire of which the different kingdoms may be regarded as the provinces. In this magnificent empire one province is favourable to the production of one species of produce, and another province of another. By their mutual intercourse mankind are enabled to distribute their labour as best fits the genius of each particular country and people. The industry of the whole is thus rendered incomparably more productive, and every species of necessary, useful, and agreeable accommodation is obtained in much greater abundance, and with infinitely less expense." (Mill's *Commerce Defended*, p. 38.)

To enter into a more enlarged discussion of this interesting and important subject would be inconsistent alike with the objects and limits of this article. In the articles on COLONIES, and the CORN LAWS AND CORN TRADE, we have examined the policy of the restrictions on the colonial and corn trades; and in the article EXCHANGE we have pointed out the circumstances which regulate the importation and exportation of the precious metals, and have shown that, instead of an excess of exports over imports being any criterion of an advantageous commerce, it is quite the reverse, and that it is by the excess of the imports over the exports that the gain of the merchants, and consequently of the community, is to be estimated. In the fourth book of the *Wealth of Nations*, Adam Smith has examined and refuted the various arguments in favour of restrictions on commerce in the most able and masterly manner, and with an amplitude of illustration which leaves little to be desired. A very complete exposure of the sophisms of the French Economists on the subject of commerce may be found in the pamphlets of Mill (*Commerce Defended*) and Colonel Torrens (*Economists Refuted*), in answer to Spence's pamphlet entitled *Britain Independent of Commerce*. And ample information on most points relating to the practice, theory, and history of commerce will be found in the *Principles of Political Economy* (4th edition), and in the *Commercial Dictionary*, by the author of this article.

When the division of labour was first introduced, commodities were universally bartered for each other. But as the division of employments was extended, and exchanges became more numerous, it became obvious that it would be highly advantageous to use some one article as a common medium of exchange, as an equivalent for all other articles, and as a standard by which to ascertain their values. It is unnecessary, however, to inquire into this subject. It has been already fully discussed in the article MONEY, in this work, to which the reader is referred for further information with respect to it.

Definition.

Accumulation and Employment of Capital. — Capital may be defined to be "*that portion of the accumulated produce of labour which may be* DIRECTLY *employed to maintain productive labourers, or to facilitate production.*"

The fitness of an article to serve as an instrument of production, or to support those engaged in industrial undertakings, is the only criterion by which to decide whether it is or is not capital. Its employment, on which much stress has been laid, depends entirely on the judgment or caprice of its owner, and affects neither its identity nor its qualities. It is frequently, also, very difficult to distinguish between what are really productive and unproductive employments; so that a definition which depended on such a distinction being made, must be of the class of those that explain *ignotum per ignotius.* But there is never, or but very rarely, any difficulty in learning whether an article may be employed to facilitate labour or maintain labourers; and that is all that is required for its proper classification. A great many articles, including pictures, prints, statues, vases, most sorts of gems, trinkets, and so forth, cannot be employed in either of the ways now referred to, and have therefore no claim to be called capital. But any article that may be so employed is entitled to that designation, however it may be disposed of. Gunpowder, for example, is capital, whether it be expended in fireworks or in the blasting of rocks; and horses have no better claim to be called capital when they are employed in ploughing and harrowing, than when they are racing at Newmarket or Goodwood.

Accumulation and employment of capital.

Having thus seen what capital is and what it is not, we proceed to observe that its accumulation and employment are indispensable to the successful prosecution of almost every branch of industry. Without the capital which chiefly consists of tools and engines, and which has been denominated *fixed*, labour could not be rendered considerably productive; and without the capital which chiefly consists of the food and clothes required for the consumption of the labourer during the time he is employed in production, and which has been denominated *circulating*, he could not engage in any undertaking which did not yield a speedy return. An agricultural labourer, for example, might have an ample supply of carts and ploughs, of oxen and horses, and generally of all the instruments and animals used in his department of industry; but were he destitute of *circulating* capital, or of food and clothes, he would be unable to avail himself of their assistance, and instead of tilling the ground, would have to betake himself to some species of appropriative industry. And, on the other hand, supposing the husbandman to be abundantly supplied with provisions, what could he do without *fixed* capital, or tools? What could the most skilful agriculturist perform without his spade and his plough? a weaver without his loom? or a house-carpenter without his saw, his axe, and his planes? Both sorts of capital are required for the elevation of every nation in the scale of civilization. And it is only by their conjoined and powerful operation that wealth is largely produced.

The division of labour in such societies as are a little advanced is consequent to the accumulation of capital. Before labour can be considerably subdivided, "a stock of goods of different kinds must be stored up somewhere, sufficient to maintain the labourer, and to supply him with the materials and tools of his work. A weaver cannot apply himself entirely to his peculiar business, unless there is beforehand stored up somewhere, either in his own possession or in that of some other person, a stock sufficient to maintain him, and supply him with the materials and tools of his work, till he has not only completed, but sold his web. This accumulation must evidently be previous to his applying his industry for so long a time to such a peculiar business." (*Wealth of Nations*, p. 119.)

As the accumulation of stock must precede all but the earliest division of labour, so its further division is more and more extended as capital is more and more accumulated. Accumulation and division act and re-act on each other. The raw material which the same number of people can work up increases according as labour is more and more subdivided; and when the operations of each workman are reduced to a greater degree of identity and simplicity, he has, as already explained, a greater chance of discovering machines and processes for facilitating and abridging labour. Industry therefore not only increases in every country with the increase of the stock or capital which sets it in motion, but, in consequence of this increase, the division of labour becomes extended, new and more powerful implements and machines are invented, and the same amount of labour produces a much greater quantity of commodities.

Besides enabling labour to be divided, capital contributes to facilitate labour and produce wealth in the three following ways:—

Modes in which t employment of capital f cilitates labour.

First.—It enables work to be executed that could not be executed, or commodities to be produced that could not be produced, without it.

Second.—It saves labour in the production of almost every species of commodities.

Third.—It enables work to be executed better, as well as more expeditiously.

1. It ena bles man produce commodi ties tha could no be prod ed with it.

With regard to the first mode in which we are benefited by the employment of capital, or its *enabling commodities to be produced that could not be produced without it*, we have seen that the production of such commodities as require a considerable period for their completion cannot be attempted until a stock of circulating capital, or of food and clothes, sufficient for the maintenance of the labourers employed on them, has been provided. But the employment of fixed capital in the shape of tools and engines is also in most cases indispensable in production. There are, indeed, very few, if any, arts that may be carried on by the mere agency of the fingers, or rude tools given to us by nature. A pair of stockings could not be produced without the aid of wires; and though the ground may be cultivated without ploughs, it could not be cultivated without spades or hoes. But man is not, like the lower animals, condemned to vegetate for ever in the situation in which he was originally placed. He is always aspiring to something better; and he has a head to contrive, as well as hands to construct the means and instruments required to assist him in his undertakings. And no sooner is one step gained, one difficulty overcome, than he advances to grapple with another. The *curis acuens mortalia corda* never ceases to operate. The spirit which it inspires is neither enervated by success nor dispirited by failure. It is perpetually urging society forward to attempt new discoveries, and to improve and perfect the inventions already made. It is this principle that has made so many natural powers subservient to our will, and armed, if we may so speak, our feeble hands with "the force of all the elements."

2. It sav labour i the production commodi ties.

In the *second* place, while the employment of capital is indispensable to the production of many descriptions of commodities, it enables a large saving of labour to be effected in the production of a still greater number, and by lowering their price, brings them within the reach of a much larger number of consumers. We have been so long accustomed to make use of the most powerful machines, that it requires a considerable effort of abstraction to become fully aware of the extent of the advantages we derive from them. But if we compare the arts practised alike in rude and civilized societies, we cannot fail to be convinced that we owe a very large portion of our superior well-being to the employment of machines of one sort or other. It is by their means that the land is cultivated, clothes manufactured, books and newspapers printed, and the products of industry, with the treasures of art and knowledge, conveyed from one country and hemisphere to another. Those who reflect, how cursorily soever, on the immeasurable distance between slings, or bows and arrows, and muskets and heavy ordnance, between the pen of a copying-clerk and a steam-press, between spindles and distaffs and spinning-mills, between a canoe and a line-of-battle or first-class merchant ship, and on fifty similar contrasts, will be ready to admit that the progress of mankind from their lowest and most abject to their highest and most polished state, has been mainly a consequence of the invention and improvement of tools and engines. Man was defined by Dr Franklin to be a "tool-making animal;" and the definition turns upon one of his distinctive and most valuable faculties, and is really one of the best that has been given.

3. It enables us to xecute ork better, as well s more xpediiously.

In the *third* place, the employment of machinery enables work to be done *better*, as well as more expeditiously, than it could be done without it. Cotton, for example, might be spun by the hand; but the admirable machines invented by Hargreaves, Arkwright, Crompton, and others, have not only enabled a hundred or a thousand times more yarn to be produced than could be spun by means of a common hand-wheel (itself a great invention), but it has also improved its quality, and given it a degree of fineness, and of evenness or equality in its parts, which was never previously attained. It would require a painter months, or it might be years, to paint with a brush the cottons or printed cloths used in the hanging of a single room; and it would be very difficult, if not impossible, for the best artist to give the same perfect identity to his figures that is given to them by the admirable machinery now used for that purpose. Not to mention the other and more important advantages derived from the invention of moveable types and printing, the most perfect manuscript—one on which years of patient and irksome labour have been expended—is unable, in point of delicacy and correctness, to match a well-printed work, executed in the hundredth part of the time, and at a hundredth part of the expense, required to copy the manuscript. The great foreign demand for English manufactured goods results no less from the superiority of their fabric than from their greater cheapness; and for both these advantages we are principally indebted to the excellence of our machinery.

e power employ our dends on amount capital.

There are other considerations which equally illustrate the extreme importance of the accumulation and employment of capital. Setting aside the variations of harvests, the produce of the land and labour of a nation cannot be increased otherwise than by an increase in the number of its labourers or of their productive powers. But without an increase of capital, it is in most cases difficult to employ additional workmen with advantage. If capital be not augmented, and if the food and clothes destined for the support of the labourers, and the tools and machines with which they are to work, be all required for the maintenance and efficient employment of those in existence at this or any other period, there can be no advantageous demand for more. In such circumstances, the rate of wages cannot rise; and if the number of inhabitants be increased, they can hardly fail to be worse provided for. Neither can the productive powers of the labourer be considerably augmented without a previous increase of capital. For it is only by their better education and training, by the greater subdivision of their employments, or by an improvement of machinery, that the productive powers of workmen are ever materially increased. And in almost all these cases additional capital is required. When the work to be done consists of a number of parts, to keep every man constantly employed in a particular part requires a larger stock than where every man is occasionally employed in different parts. "When," says Adam Smith, "we compare the state of a nation at two different periods, and find that the annual produce of its land and labour is evidently greater at the latter than at the former, that its lands are better cultivated, its manufactures more numerous and more flourishing, and its trade more extensive, we may be assured that its capital must have increased during the interval between these two periods, and that more must have been added to it by the good conduct of some, than had been taken from it either by the private misconduct of others or by the public extravagance of government." (*Wealth of Nations*, p. 152.) It is therefore apparent that no country can ever reach the stationary state so long as she continues to add to her capital. While she does this, she will have an increasing demand for labour, and will be constantly augmenting the mass of necessaries, luxuries, and conveniences, and consequently also the numbers of her people. But with every diminution of the rate at which capital may have been accumulating, the demand for labour will decline. When no additions are made to capital, no more labour will be, or at least can be, beneficially employed. And should the national capital be diminished, the condition of the great body of the people would be deteriorated; for the wages of labour would be reduced, and pauperism, with its attendant train of vice, misery, and crime, would begin to spread its ravages throughout the largest portion of society.

Accumulation of capital.

Having thus endeavoured to point out the vast importance of the employment of capital, and the manner in which it co-operates in production, we proceed to explain the circumstances most favourable for its accumulation.

Advantage of high profits.

Now, as capital is nothing but the accumulated produce of bygone industry, it is evident that its increase will, *cæteris paribus*, be greatest where industry is most productive, or, in other words, where *the profits of stock are highest*.[1] A man who produces a bushel of wheat in two days may accumulate twice as fast as a man who, either from a deficiency of skill, or from having to cultivate a bad soil, has to labour four days to produce the same quantity; and capitalists who invest stock so as to yield a profit of ten per cent., have it equally in their power to accumulate twice as fast as those who can only obtain five per cent. on their outlays. Experience, too, shows that while large profits afford greater means of saving, they act as incentives to accumulation. Hence it is found that in the countries which are making the greatest progress, the rate of profit is always comparatively high. In Australia and the United States, for example, it is usually twice as high as in Great Britain or France; and it is to this that the more rapid advancement of the former in wealth and population is mainly to be ascribed. We do not mean to say that high profits are necessarily and in every instance accompanied by a great degree of prosperity. Countries with every other advantage for the profitable employment of industry and stock, may be subjected to revolutionary and arbitrary governments which do not respect the right of property; and the want of security thence resulting may be sufficient to paralyze their exertions, and to hinder them from accumulating capital. But we have no hesitation in laying it down as a principle which holds universally, that if the governments of any two or more countries be about equally liberal, and property in each about equally well secured, their comparative prosperity will depend on the rate of profit. Where profits are high, there is a great demand for labour, and population and riches are rapidly augmented; and where they are low, the demand for labour is proportionally reduced, and the progress of society rendered so much the slower.

---

[1] To avoid all chance of misconception, it is necessary to observe, that this refers to *nett* profit, or to the sum which remains to the capitalist after all his outgoings are compensated, including therein a sum sufficient to insure his capital against risk, and to make up for whatever may be peculiarly disagreeable in his business.

Parsimony necessary to accumulation.

But however high the rate of profit, had men always lived up to their incomes,—that is, had they always consumed them in the gratification of their immediate wants and desires,—there would have been no such thing as capital in the world. High profits are advantageous because they afford the means of amassing capital; but something more is necessary to make us use these means, and that is the desire implanted in the breasts of all, or mostly all individuals, of rising in the world, and improving their condition. This strong desire has prompted them, as already seen, to invent machines and instruments; and it also prompts them to save and accumulate a portion of their incomes or earnings as a fund or capital to be employed in their future undertakings, or invested in loans to others, or retained as a reserve stock on which to fall back in sickness or adversity. Hence it is to the principle of accumulation, or rather to its source, parsimony, which, though one of the most useful, is one of the least popular of the virtues, that we owe that capital without whose assistance and co-operation mankind could have made no considerable progress, and would most likely have continued in a state but little removed from barbarism.

Bacon objects to parsimony, that "it withholdeth men from works of liberality and charity." (*Essays*, No. 34.) But unless a man be born to affluence, which is the lot of few, the exercise of parsimony is required to enable him to be really charitable. Those who spend as fast as they acquire are almost always in difficulties; they live, as the phrase is, from hand to mouth; and are without the means, even if they had the inclination, to act liberally. But it is not necessary to the practice of a proper degree of parsimony that people should submit to painful privations, or that they should behave in a mean or niggardly manner. Parsimony is not to be confounded with the base passion of avarice. It does not regard accumulation as an end, but only as a means to an end; and it should correspond to, and be consistent with, a man's situation and prospects. And, in truth, it is everywhere found that the establishments of those parties, whether in the lower, middle, or upper classes, who are said to be saving or parsimonious, are more distinguished by their good order and the avoidance of waste than by anything else. They do not deny themselves gratifications, but they keep the taste for them within due bounds, and do not allow their means to be made away with (as many do), they know not how. They are careful and economical upon principle, and add to their fortunes that they may be able to live better, and be more hospitable and generous. Cicero says of Rabirius Postumus, "*In augenda re non avaritiæ prædam, sed instrumentum bonitati quærere videretur.*" (Pro Rabirio Postumo, cap. 2.)

It has been wisely ordered that this principle should be as powerful as it is advantageous. "With regard to profusion," says Smith, "the principle which prompts to expense is the passion for present enjoyment; which, though sometimes violent, and very difficult to be restrained, is in general only momentary and occasional. But the principle which prompts to save is the desire of bettering our condition; a desire which, though generally calm and dispassionate, comes with us from the womb, and never leaves us till we go into the grave. In the whole interval which separates these two moments there is scarce perhaps a single instance in which any man is so perfectly and completely satisfied with his situation as to be without any wish of alteration or improvement of any kind. An augmentation of fortune is the means by which the greater part of men propose and wish to better their condition. It is the means the most vulgar and the most obvious; and the most likely way of augmenting their fortune is to save and accumulate some part of what they acquire either regularly and annually, or upon some extraordinary occasion. Though the principle of expense, therefore, prevails in almost all men upon some occasions, and in some men upon almost all occasions, yet in the greater part of men, taking the whole course of their life at an average, the principle of frugality seems not only to predominate, but to predominate very greatly." (*Wealth of Nations*, p. 151.)

It is this principle which carries society forward. The spirit of parsimony, and the efforts which the frugal and industrious classes make to improve their condition, in most instances balance not only the profusion of individuals, but also the more wasteful profusion and extravagance of government. This spirit has been happily compared by Smith to the unknown principle of animal life—the *vis medicatrix naturæ*—which frequently restores health and vigour to the constitution, in spite both of disease and of the mischievous prescriptions of the physician.

But though the principle of accumulation be powerful enough, when its vigorous action is not paralysed by any fear of insecurity, to make good the waste or loss of large amounts of capital, we must not fall into the error of supposing, as very many have done, that its operations are in all cases promoted by a large public expenditure. To a certain extent, indeed, this is true. A moderate increase of taxation has the same effect on the habits and industry of a nation that an increase of his family or of his unavoidable expenses has upon a private individual. Man is not influenced solely by hope; he is also powerfully operated upon by fear. Taxation brings the latter principle into the field. To the desire of rising in the world, an increase of taxation superadds the fear of being cast down to a lower station, of losing consideration, and of being deprived of conveniences and gratifications which habit may have rendered almost indispensable: and the combined influence of the two principles produces efforts that could not be produced by the unassisted agency of either. They stimulate individuals to endeavour, by increased efforts of industry and economy, to repair the breach taxation has made in their fortunes. And it not unfrequently happens that their efforts do more than this, and that, consequently, the national wealth is increased through the increase of taxation. But we must be on our guard against the abuse of this doctrine. To render increased taxation a cause of greater exertion, economy, and invention, the increase should be slow and gradual; and it should never be carried to such a height as to disable individuals from meeting the sacrifices it imposes, by such additional exertion and economy as it may be in their power to make, without requiring any very sudden or violent change in their habits. Difficulties which, though great, are seen to be surmountable, sharpen the inventive powers, and are readily grappled with. But an apparently insurmountable difficulty, or such an excessive increase of taxation as it was deemed impossible to meet, would not stimulate, but destroy exertion. Instead of producing new efforts of ingenuity and economy, it would produce only despair. Whenever taxation becomes so heavy that the produce it takes from individuals cannot be replaced by fresh efforts of economy and invention, these efforts uniformly cease to be made; the population becomes dispirited, industry is paralysed, and the country rapidly declines.

Ambition to rise is, we repeat it, the animating principle of society. Instead of remaining satisfied with the condition of their fathers, the great object of mankind in every age has been to rise above it, to elevate themselves in the scale of consideration and of wealth. To achieve this grand object, they scruple not

> "Certare ingenio, contendere nobilitate
> Noctes atque dies niti præstante labore
> Ad summas emergere opes, rerumque potiri."[1]

To continue stationary, or to retrograde, is not natural to society. Man from youth grows to manhood, then decays and dies; but such is not the destiny of nations. The arts, the scientific discoveries, and the capital of one generation become the patrimony of that which succeeds them; and as the former are imperishable, and will continue to give birth to new arts and new discoveries in all time to come, while the natural tendency of the latter is to increase, it follows that, if not counteracted by the want of security, or by other adventitious causes, the principle of improvement would always operate, and would secure the constant advancement of nations in wealth and population.

Credit.

It may be said perhaps that, however true, the previous statements are incomplete, from no mention being made of *credit*, which, we are assured, plays an important part in all industrial operations. But this is an entire mistake. Credit is not capital, nor even anything real. It is merely the term employed to designate the lending or transfer of capital by one individual to another. The lender is said to give, and the borrower to get or receive credit. No doubt we often hear of this, that, and the other undertaking being carried on by means of credit; but by this is really meant that they are carried on by the agency of borrowed capital. And speaking generally, the giving of credit or the lending of capital may be said to be advantageous, because in most instances the borrowers employ it to better purpose than the lenders. When, however, it is otherwise, and capital is conveyed, as is sometimes the case, from the industrious and frugal to the idle and improvident, the credit that has been given is plainly injurious. And in all cases its influence, whether for good or for evil, depends on the capital being employed more or less advantageously after its transfer than before.

SECT. III.—*Different Employments of Capital and Industry.—Manufactures and Commerce shown to be equally advantageous as Agriculture.—Rate of Profit a true Test of Individual and Public Advantage.*

ifferent nploy- ents of pital and dustry.

In the previous section we endeavoured to show that the increase and diminution of capital is the pivot on which national prosperity principally hinges; that an increase of capital proportionally increases the means of supporting and employing labour, and that any considerable diminution of its amount seldom fails to lessen the comforts and enjoyments, and perhaps also the necessaries of the productive classes, and to spread poverty throughout the land; and we also endeavoured to show that the increase and diminution of the rate of profit is the great cause of the increase and diminution of capital. But if such be the case, it would seem necessarily to follow that those employments which yield the greatest profit, or in which industry is most productive, are the most advantageous. Adam Smith, however, with Malthus and others, have objected to this inference. They allow that if two capitals yield equal profits, the employments in which they are engaged are equally beneficial to their possessors; but they contend that if one of them be employed in agriculture, it will be productive of greater public advantage. We believe, however, notwithstanding the deference due to the authorities referred to, that this opinion rests on no good foundation, and that the average rate of profit is the test by which we should always judge which employment is most and which is least advantageous.

A capital may be employed in *four* different ways,—viz., *first*, In the acquisition of raw products; or, *secondly*, In manufacturing and preparing these raw products for use and consumption; or, *thirdly*, In transporting the raw and manufactured products from one place to another, according to the demand; or, *fourthly*, In dividing either into such small parcels as may suit the public convenience, and supplying them to those by whom they are wanted. The capital of those who undertake the improvement or cultivation of lands, mines, or fisheries, is employed in the first of these ways; that of master manufacturers in the second; that of wholesale merchants in the third; and that of retailers in the fourth. It is difficult to conceive that a capital should be employed in any way which may not be classed under one or other of these heads.

Employment of capital in agriculture.

It is unnecessary to enlarge on the importance of employing capital in the acquisition of raw produce, and especially in the cultivation of the soil. It is from the latter, including therein mines and fisheries, that the matter of all commodities that minister to our necessities, comforts, and enjoyments is originally derived. The industry which appropriates the raw or spontaneous products of the earth preceded every other. But these are always comparatively limited. And it is by agriculture only,—that is, by the united application of immediate labour and capital to the cultivation of the ground,—that large supplies of those species of produce which form the principal part of the food of man can be obtained. It is not quite certain whether any of the principal bread corns, as wheat, barley, rye, oats, &c., have been discovered growing spontaneously. But although this must originally have been the case, their extreme scarcity, and the labour required to raise them in considerable quantities, prove that we are indebted for them almost exclusively to agriculture. The transition from the pastoral to the agricultural mode of life is the most important step in the progress of society. Whenever, indeed, we compare the supplies of food and other raw products obtained from a given surface of a well-cultivated country, with those obtained from the same extent of an equally fertile country occupied by hunters or shepherds, the powers of agricultural industry in increasing useful productions appear so extraordinary, that we cease to feel surprise at the preference which was so early and generally given to agriculture over manufactures and commerce, and are disposed to subscribe without hesitation to the panegyric of Cicero when he says, "*Omnium autem rerum ex quibus aliquid acquiritur, nihil est agricultura melius, nihil uberius, nihil dulcius, nihil homine libero dignius.*"[2]

But are there any really just grounds for this preference? Are not manufactures and commerce as advantageous as agriculture? Without the latter we should never possess any considerable supply of the materials out of which food

---

[1] Lucretius, lib. ii., lin. 14.

[2] Xenophon, in his treatise on the *Science of Good Husbandry*, dwells at considerable length on the superior importance of agricultural industry. He says, "The earth gives us plenty of all things, yet (he judiciously adds) it does not allow us to reap them in sloth and idleness, but excites us to health and strength by the labour it appoints us." And in another place he says, "He was surely a wise man who said that husbandry was the mother and nurse of all other sciences; for if husbandry flourish, all other sciences and faculties fare the better; but whenever the ground lies uncultivated, and brings no crop, all other sciences are at a loss, both by sea and land." (Bradley's trans. of Xenophon's *Œconomics*, London, 1727.)

Employment of capital in manufacturing industry.

and clothes are made; but without a knowledge of the arts by which they are converted into food and clothes the largest supply of these materials would be of little or no service. The industry of the miller and baker is as necessary to the production of bread as that of the husbandman who tills the ground. The agriculturists raise flax and wool; but if the spinners and weavers did not give them additional utility, by fitting them for being made into comfortable dresses, these articles would be nearly, if not entirely, worthless. Without the labour of the miner who extracts the mineral from the bowels of the earth, we should be destitute of the material out of which many of our most useful implements and splendid articles of furniture are made; but those who compare the ore when dug from the mine with the finished articles, will probably be convinced that we do not owe more to the miner than to the purifiers and refiners of the ore, and the artists who afterwards converted it to useful purposes.

Necessity of manufacturing industry to the improvement in agriculture.

Besides being necessary to render most sorts of raw produce of any use, manufacturing industry is further necessary to the acquisition of that produce. The mechanic who fabricates the plough contributes as efficaciously to the production of corn as the husbandman who guides it. But plough-wrights, mill-wrights, smiths, and all those artizans who prepare tools and machines for the husbandman, are really manufacturers, and differ in no respect from those employed to give utility to wool and cotton, except that they work on harder materials. Tools and machines are the products of the tool and engine manufacturer; and without their aid neither agriculture nor any other employment could become considerably productive.

"Distinguer," says the Marquis Garnier, "le travail des ouvriers de l'agriculture d'avec celui des autres ouvriers, est une abstraction presque toujours oiseuse. Toute richesse, dans le sens dans lequel nous la concévons, est nécessairement le résultat de ces deux genres de travail, et la consommation ne peut pas plus se passer de l'un que de l'autre. Sans leur concours simultané il ne peut y avoir de chose consommable, et par conséquent point de richesse. Comment pourrait-on donc comparer leurs produits respectifs, puisque, en séparant des deux espèces de travail, on ne peut plus concévoir de véritable produit, de produit consommable et ayant une valeur réele? La valeur du blé sur pied résulte de l'industrie du moissonneur qui récueillera, du batteur qui le séparera de la paille, du méunier et du boulanger qui le convertiront successivement en farine et en paine, tout comme elle résults du travail du labourer et du sémeur. Sans le travail du tisserand le lin n'aurait pas plus le droit d'être compté au nombre des richesses que l'ortie, ou tout autre végétal inutile. A quoi pourrait-il donc servir de rechercher lequel de ces deux genres de travail contribue le plus à l'avancement de la richesse nationale? N'est-ce pas comme si l'on disputait pour savoir lequel, du pied droit ou du pied gauche, est plus utile dans l'action de marcher?"[1]

No real difference between agricultural and manufacturing industry.

There is not at bottom any real distinction between agricultural and manufacturing industry. It is, as already seen, a vulgar error to suppose that the operations of husbandry add anything to the stock of matter in existence. All that man can do, and all that he ever does, is to give to matter that particular form or shape which fits it for his use. But it was contended by Quesnay and the Economists, and their opinions have in this instance been espoused by Smith, that while the husbandman, in adapting matter to our use, is powerfully assisted by the vegetative powers of nature, the manufacturer has to perform everything himself without any such co-operation. "No equal quantity of productive labour employed in manufactures," says Smith, "can ever occasion so great a reproduction (as if it were employed in agriculture). In them *nature does nothing, man does all;* and the reproduction must always be in proportion to the strength of the agents that occasion it. The capital employed in agriculture, therefore, not only puts into motion a greater quantity of productive labour than any equal capital employed in manufactures, but in proportion, too, to the quantity of productive labour which it employs it adds a much greater value to the annual produce of the land and labour of the country, to the real wealth and revenue of its inhabitants. Of all the ways in which a capital can be employed, it is by far the most advantageous to the society." (*Wealth of Nations*, p. 162.)

Opinion of Smith respecting the superior productiveness of agriculture.

Error of this opinion.

This is perhaps the most objectionable passage in the *Wealth of Nations;* and it is astonishing that so able and sagacious a reasoner as Smith should have maintained a doctrine so manifestly erroneous. It is unquestionably true that nature powerfully assists the husbandman. He prepares the ground for the seed, and deposits it therein; but it is nature that unfolds the germ, that feeds and ripens the growing plant, and brings it to maturity. But does she not do as much for us in every other department of industry? The powers of water and of wind which move our machinery, support our ships, and impel them over the deep,—the pressure of the atmosphere and the elasticity of steam, which enable us to work the most stupendous engines,—are they not spontaneous gifts of nature? Machines are in truth merely contrivances by which we press natural powers into our service, and make them perform the principal part of what would otherwise be wholly the work of man. In navigation, for example, is it possible to doubt that the powers of nature,—the buoyancy of the water, the impulse of the wind, and the polarity of the magnet,—contribute fully as much as the labour of the sailor to waft our ships from one hemisphere to another. In bleaching and fermentation the whole processes are carried on by natural agents. And it is to the influence of heat in softening and melting metals, preparing food, and warming houses, that we owe many of our most powerful and convenient instruments, and that these northern climates have been made to afford a comfortable habitation. So far, indeed, is it from being true that nature does much for man in agriculture and nothing in manufactures, that the fact is more nearly the reverse. There are no limits to her bounty in manufactures, but there are limits, and those not very remote, to her bounty in agriculture. Any amount of capital may be expended in the construction of steam-engines, ships, or other machines, and, however largely they may be multiplied, the last, apart from the improvements which are usually being made, will be as powerful and efficient as the first. But such is not the case with the soil. Lands of the first quality are speedily exhausted; and capital cannot be applied indefinitely, even to the best soils, without obtaining a diminished rate of profit. The rent of the landlord is not, as Smith supposed, the recompense of the work of nature remaining, after all that part of the produce is deducted which may be regarded as a recompense for the work of man. It is, as will hereafter be shown, the excess of produce obtained from the best soils in cultivation over that which is obtained from the worst,—it is a consequence, not of an increase, but of a diminution of the productive power of the labour employed in agriculture.

Nature co-operates with man in manufactures and commerce.

Employment of capital in commercial industry.

Inasmuch as all labour which gives utility to matter is productive, it follows that the labour which is employed in carrying commodities from where they are produced to where they are to be consumed, and in dividing them into minute portions, so as to suit the wants of the consumers, is as much entitled to that designation as if it were employed in agriculture or manufactures. The miner gives utility to matter, to coal, for example, by bringing it from the bowels of the earth to its surface; and the merchant or carrier, who transports this coal from the mine whence it has been dug to the city, or place where it is to be burned, gives it a further and perhaps a more considerable value. We do not owe our fires either to the miner or coal-merchant. They are the result of their conjoined operations, combined with those of the parties who have supplied them with the tools and implements used in their respective employments.

[1] *Discours Préliminaire*, p. 58, 2d ed. of trans. of the *Wealth of Nations.*

dvantage f retail ealers.

Not only, however, must commodities be brought from where they are produced to where they are to be consumed, but it is further necessary that they should be divided into such small and convenient portions that individuals may be able to purchase the quantities they are desirous to obtain. "If," says Smith, "there was no such trade as a butcher, every man would be obliged to purchase a whole ox or a whole sheep at a time. This would generally be inconvenient to the rich, and much more so the poor. If a poor workman was obliged to purchase a month's or six months' provisions at a time, a great part of the stock which he employs as a capital in the instruments of his trade, or in the furniture of his shop, and which yields him a revenue, he would be forced to place in that part of his stock which is reserved for immediate consumption, and which yields him no revenue. Nothing can be more convenient for such a person than to be able to purchase his subsistence from day to day, or even from hour to hour, as he wants it. He is thereby enabled to employ almost his whole stock as a capital. He is thus enabled to furnish work to a greater value, and the profit which he makes by it in this way much more than compensates the additional price which the labour of the retailer imposed upon the goods. The prejudices of some political writers against shopkeepers and tradesmen are altogether without foundation. So far is it from being necessary either to tax them or to restrict their numbers, that they can never be multiplied so as hurt the public interest, though they may so as to hurt one another. The quantity of grocery goods, for example, which can be sold in a particular town is limited by the demand of that town and its neighbourhood. The capital, therefore, which can be employed in the grocery trade cannot exceed what is sufficient to purchase that quantity. If this capital is divided between two different grocers, their competition will obviously tend to make both of them sell cheaper than if it were in the hands of one only; and if it were divided among twenty, their competition would be just so much the greater, and the chance of their combining together in order to raise the price just so much the less. Their competition might perhaps ruin some of themselves; but to take care of this is the business of the parties concerned, and it may safely be trusted to their discretion. It can never hurt either the consumer or the producer; on the contrary, it must tend to make the retailers both sell cheaper and buy dearer than if the whole trade was monopolized by one or two persons. Some of them perhaps may occasionally decoy a weak customer to buy what he has no occasion for. This evil is, however, of too little importance to deserve the public attention, nor would it necessarily be prevented by restricting their numbers." (*Wealth of Nations*, p. 160.)

gricul-re, manu-ctures, d com-erce ually ad-ntageous.

Thus it appears that the various modes in which industry may be exerted, or that the raising of raw produce, the fashioning of that produce, after it is raised, into useful and agreeable articles, the carrying of the raw and manufactured products from one place to another, and the retailing them in such portions as may suit the public demand, are equally advantageous,—meaning thereby, that the capital and labour employed in any one of these departments contributes, equally with that employed in the others, to increase the mass of articles fitted to satisfy our wants or desires. Without a previous supply of raw produce, we should have no manufactures; and without these and commercial industry, the greater part of that produce would be entirely worthless, and would neither minister to our wants or our comforts. Manufacturers and merchants are to the body politic what the digestive powers are to the human body. Food is indispensable to existence; but the largest supplies of food cannot lengthen our days if the machinery by which nature adapts it to our use, and incorporates it with our body, be vitiated and deranged. Nothing, therefore, can be more silly and childish than the estimates so frequently put forth of the comparative advantageousness of agricultural, manufacturing, and commercial industry. They are alike indispensable, and depend upon, and grow out of, each other. "Land and trade," to borrow the just and forcible expressions of Sir Josiah Child, "are twins, and have always, and ever will, wax and wane together. It cannot be ill with trade but lands will fall, nor ill with lands but trade will feel it." This reasoning cannot be controverted; and on its authority we are entitled to condemn every attempt to exalt one species of industry, by giving it factitious advantages, as being both impolitic and pernicious. It must be done at the expense of the others; and no preference can be given to agriculturists over manufacturers and merchants, or to the latter over the former, without having prejudicial results. Wherever industry is free, the interests of individuals and the public always coincide. And those who, in such circumstances, succeed best in increasing their own wealth necessarily also succeed best in increasing the wealth of the state of which they are subjects.

This dependence of the different branches of industry on each other, and the necessity of their co-operation to enable mankind to make any considerable progress in civilization, have been ably illustrated in an early number of the *Edinburgh Review*:—"It may safely be concluded, that all those occupations which tend to supply the necessary wants or to multiply the comforts and pleasures of human life, are equally productive, in the strict sense of the word, and tend to augment the mass of human riches,—meaning by riches all those things which are necessary, or convenient, or delightful to man. The progress of society has been productive of a complete separation of employments originally united. At first every man provided, as well as he could, for his necessities as well as his pleasures, and for *all* his wants as well as *all* his enjoyments. By degrees a division of these cares was introduced; the subsistence of the community became the province of one class, its comforts of another, and its gratifications of a third. The different operations subservient to the attainment of each of these objects were then entrusted to different hands; and the universal establishment of barter connected the whole of these divisions and subdivisions together,—enabled one man to manufacture for all, without danger of starving by not ploughing or hunting, and another to plough or hunt for all, without the risk of wanting tools or clothes by not manufacturing. It has thus become as impossible to say exactly who feeds, clothes, or entertains the community, as it would be to say which of the many workmen employed in the manufacture of pins is the actual pin-maker, or which of the farm-servants produces the crop. All the branches of useful industry work together to the common end, as all the parts of each branch co-operate to its particular object. If you say that the farmer feeds the community, and produces all the raw materials which the other classes work upon, we answer, that unless those other classes worked up the raw materials, and supplied the farmer's necessities, he would be forced to allot part of his labour to this employment, whilst he forced others to assist in raising raw produce. In such a complicated system it is clear that all labour has the same effect, and equally increases the whole mass of wealth. Nor can any attempt be more vain than theirs who would define the particular parts of the machine that produce the motion, which is necessarily the result of the *whole powers combined*, and depends on each particular one of the mutually-connected members." (Vol. iv., p. 362.)

Division of labour does not degrade the labourer.

The extent to which the division of labour is carried in manufacturing establishments, and the exclusive attention which it requires the workman to bestow on one operation, or on some portion thereof, has been supposed to exert a highly pernicious influence over his mental faculties. But we have seen that this is an exceedingly erroneous supposition, and that, in truth and reality, the work-people engaged in manufactures are, speaking generally, more intelligent than the ordinary run of agricultural labourers. (See MANUFACTURES.)

Manufactures not productive of increased mortality.

Much also has been said respecting the extraordinary mortality of large manufacturing establishments. The ready communication of contagion where people are crowded together,—the want of sufficient ventilation,—the confinement of children,—and the positive unhealthiness of some processes,—are circumstances from which most writers have been led to infer that the mortality in manufacturing cities *must* be unusually great, without giving themselves the trouble to inquire whether it really was so. The returns under the population acts have shown the fallacy of these opinions. Great Britain is at present infinitely more of a manufacturing country than in 1780; but, notwithstanding the vast increase during the intermediate period of what we have been in the habit of considering unhealthy employments, the average mortality in England and Wales in 1856 and 1857 was less than one in every forty-seven[1] of the existing population, whereas in 1780 it was probably more than one in every thirty-five. It may perhaps be said that this increased healthiness is mainly owing to improvements in agriculture,—to the drainage of bogs and marshes, the inclosure and cultivation of commons and wastes,—the influence of which has counteracted the increase of manufactures. But suppose this were admitted, we should have to inquire what had occasioned these extraordinary improvements in agriculture. And a moment's reflection would suffice to convince us that they have principally resulted from the improvement and extension of manufactures, and the consequently increased demand of the manufacturing population for the produce of the soil. A good deal, however, of the diminution of mortality is a direct rather than an indirect consequence of the circumstances referred to. Every one knows the vast importance, in respect of health, of people being supplied with comfortable clothes at a cheap rate. And that is one of the many advantages which grow out of improved manufactures. The reduction in the price of cotton goods, to notice one only of innumerable instances, occasioned by the greater facility with which they are produced, enables the poorer classes to clothe themselves in a comfortable and elegant dress, and is productive of an increase of enjoyment, of which it is difficult to estimate the extent.

Eulogium of Malthus on manufactures.

Malthus, whose leanings were all on the side of agriculture, has justly observed that "Most of the effects of manufactures and commerce on the general state of society are in the highest degree beneficial. They infuse fresh life and activity into all classes of the state, afford opportunity for the inferior orders to rise by personal merit and exertion, and stimulate the higher orders to depend for distinction upon other grounds than mere rank and riches. They excite invention, encourage science and the useful arts, spread intelligence and spirit, inspire a taste for conveniences and comforts among the labouring classes, and, above all, give a new and happier structure to society, by increasing the proportion of the *middle classes*,—that body on which the liberty, public spirit, and good government of every country must mainly depend." (*Observations on the Effects of the Corn Laws*, p. 29.)

Hence it would seem that those engaged in the different channels of employment contribute in nearly equal degrees to the general wellbeing; and though some rank higher in the public estimation than others, they are not on that account more indispensable. "The great author of order hath distributed the ranks and offices of men in order to mutual benefit and comfort, that one man should plough, another thresh, another grind, another labour at the forge, another knit or weave, another sail, another trade, another supervise all these, labouring to keep them all in order and peace; that one should work with his hands and feet, another with his head and tongue; all conspiring to the common end—the welfare of the whole, and the supply of what is useful to each particular member; every man so reciprocally obliging and being obliged; the prince being obliged to the husbandman for his bread, to the weaver for his clothes, to the mason for his palace, to the smith for his sword; those being all obliged to him for his vigilant care in protecting them, for their security in pursuing the work, and enjoying the fruit of their industry." (Barrow's Third Sermon on Industry.)

Rate of profit true test of the advantageousness of different employments.

Thus, from whatever point of view we may regard the division and combination of employments, we come to the same result. The inextinguishable passion for gain—the *auri sacra fames*—will always lead individuals to employ themselves and their stocks in those branches of industry in which, all things considered, wages and profits are highest. And we have seen that these are the employments in which it is most for the public interest that capital should be invested. The profits of a particular branch of industry are rarely raised except by an increased demand for its produce. Should the demand for cottons, owing to their being substituted for other articles now in use, be considerably augmented, their price would rise, so as to yield the manufacturers comparatively high profits. But profits in different employments constantly tend to equality; and they can never, unless monopolies interpose, continue either permanently higher or lower in one than in others. Whenever, therefore, the rise in the price of cottons had taken place, the manufacturers engaged in the trade would put forth all their energies and borrow additional capital, at the same time that a number of capitalists engaged in less lucrative employments would contract their engagements, and transfer a portion of their stock to where it would yield a larger return. The equilibrium of profit would thus be again restored. For the additional impetus given to the production of cottons, by proportioning their supply to the increased demand, would infallibly reduce their price to its proper level. Such is the mode in which the interests of individuals are in every case rendered subservient to those of the public. High profits attract capital; but high profits in particular businesses are the effect of high prices; and these are always reduced, and the commodities brought within the command of a greater number of purchasers, as soon as additional capital and work-people have been employed in their production. It is plain, therefore, that that employment is the best which yields the greatest profit; and if two capitals yield equal profits, it is a proof that the departments of industry in which they are respectively invested, how much soever they may differ in many respects, are equally beneficial. Nothing can be more nugatory than to apprehend that, under a free system, capital or work-people will be attracted to a disadvantageous employment. The one is determined by high profits, and the other by high wages; and their subservience to this irresistible influence is not more for their own than for the public advantage.

---

[1] In 1856 the mortality was 1 in 49, and in 1857 it was 1 in 46.

PART III.

DISTRIBUTION OF WEALTH.

Having thus endeavoured to trace the various methods by which that labour which is the only source of wealth may be rendered most productive, and to exhibit the relation and dependence of the different kinds of industry, we proceed to the third division of our subject, or to an investigation of the laws regulating the proportions in which the various products of art and industry are distributed among the different classes of the people.

Sect. I.—*Primary Division of the Produce of Industry.—Value of Commodities measured in the Earliest Stages of Society by the Quantities of Labour expended in their Production.*

'rimary ivision of ne pro- uce of ndustry.

It is evident that only three classes—labourers, capitalists, and owners of land—can be directly concerned in the production of commodities. It is to them, therefore, that all that is derived from the surface of the earth, or from its bowels, by the united application of immediate labour and capital, must primarily belong. The other classes, if such there be, have no revenue except what they derive, either voluntarily or by compulsion, from these three classes.

But although there be no state of society in which any class besides labourers, landlords, and capitalists, participates directly in the produce of industry, there are states of society in which that produce belongs to one only of these classes; and others in which it belongs to two of them, to the exclusion of the third. The reason is, that in the earlier stages of society, little or no capital being accumulated, there is no distinction between labourers and capitalists; and that, in all newly-settled and unappropriated countries, abundance of fertile lands may be obtained without paying any rent.

uantity of ibour the gulating inciple value.

In that remote period which preceded the establishment of property in land, and the accumulation of capital or stock,—when men roamed, without any settled habitations, over the surface of the earth, and existed by the appropriation of its spontaneous productions,—the whole produce of labour belonged to the labourer, and the quantity of it required to procure different articles formed the only standard by which their relative worth or exchangeable value could be estimated. "If among a nation of hunters," says Adam Smith, "it usually costs twice the labour to kill a beaver that it does to kill a deer, one beaver would naturally exchange for or be worth two deer. It is natural that what is usually the produce of two days' or two hours' labour should be worth double of what is usually the produce of one day's or one hour's labour.

"If the one species of labour should be more severe than the other, some allowance will naturally be made for this superior hardship; and the produce of one hour's labour in the one way frequently exchanges for that of two hours' labour in the other.

"Or if the one species of labour requires an uncommon degree of dexterity and ingenuity, the esteem which men have for such talents will naturally give a value to their produce superior to what would be due to the time employed about it. Such talents can seldom be acquired but in consequence of long application; and the superior value of their produce may frequently be no more than a reasonable compensation for the time and labour which must be spent in acquiring them. In the advanced state of society, allowances of this kind, for superior hardship and superior skill, are commonly made in the wages of labour; and something of the same kind must probably have taken place in the earliest and rudest period.

"In this state of things, the whole produce of labour belongs to the labourer; and the quantity of labour commonly employed in acquiring or producing any commodity is the only circumstance which can regulate the quantity of labour (of other commodities) which it commonly ought to purchase, command, or exchange for." (*Wealth of Nations*, p. 22.)

Thus far there is no room for doubt or difference of opinion. Where there are none but labourers, they only can share in its produce; and the quantity of labour required to produce articles or procure services forms the only standard by which their value is estimated. It is at this point, therefore, that the investigation of the laws which regulate the division of the produce of industry among the three great classes of labourers, capitalists, and landlords should properly begin: and we shall commence it by endeavouring, in the first place, to acquire a knowledge of the laws which determine the value of commodities in an advanced period of society, when circulating and fixed capital are employed in their production, and when land is appropriated and rent paid. A previous acquaintance with these laws is necessary to ascertain the principles which regulate their distribution.

Sect. II.—*Preliminary Considerations.—Equality of Wages and Profits.—Inquiry into the Effect of Variations of Demand and Supply on Value and Price.—Cost of Production shown to be their regulating Principle.*

Preliminary considerations.

If the popular opinions on this subject were well founded, the inquiry on which we are about to enter might be disposed of in a few words. The value of commodities, when compared with each other, and their value or price when compared with money, is held almost universally to depend on their abundance or scarcity in the market, compared with the demand. But though this statement has some it has but a very small admixture of truth. And it will be found that the prices of commodities are determined, speaking generally, by the cost of their production,—that is, by the quantities of labour required to produce them and bring them to market. Before, however, we proceed further, it may be proper, the better to facilitate our investigations in this and the following sections, to premise, that wherever industry is free, the rate of wages earned by the labourers in specified departments, and the rate of profit derived from the capital vested in them cannot, for any considerable period, taking everything into account, either fall below or rise above the rates of wages and profits accruing to the labourers and capitalists engaged in other departments.

Equality of the wages earned by the labourers engaged in different branches of industry.

With regard to the *first* of these positions, or the equality of the wages earned by those engaged in different employments, it is not meant to infer that all labourers receive precisely the same sum of money, or the same proportion of the produce of their labour. Such an opinion would be equally at variance with fact and with principle. Wages are a compensation made to the labourer for the exertion of his physical powers, or of his skill or ingenuity. They therefore vary according to the greater intensity of the labour to be performed, and to the degree of skill and ingenuity required. Wages would not be equal if a jeweller or engraver, for example, received no more than a common farm-servant or scavenger. A long course of training is required to instruct a man in the businesses of jewellery and engraving; and if this were not compensated by a higher rate of wages, none would choose to learn such difficult arts, and all persons would addict themselves, in preference, to such employments as hardly require any training. The cost of producing artificers or labourers regulates the wages they obtain, in the same way that the cost of producing commodities regulates their value. Artizans who practise a difficult or nice business lose all the time spent in their apprenticeship, as well as the clothes and provisions consumed during its currency. Hence, in addition to the rate paid to farm-servants and those who get little or no training, their wages should include a payment for the extra time and expense required to learn their business. If they be either more or less than are sufficient to compensate for this greater outlay on their education, work-people will, in the former case, be attracted to their peculiar departments, and in the latter they will leave them to go to others; this influx on the one hand, and efflux on the other, being sure to continue till wages have found their just and true level.

Besides this prominent cause of apparent inequality, wages vary in amount proportionally to the ease and hardship, the agreeableness and disagreeableness, the constancy and inconstancy, of employment. In the greater number of manufactures a journeyman may, except in periods of general distress, usually obtain constant employment. But there are several businesses, such as those of masons and bricklayers, that can neither be carried on in hard frost nor foul weather. Their earnings should therefore be sufficient not only to maintain them while they are employed, but also while they are idle, and to make them some compensation for those anxious and desponding moments which the thought of so precarious a situation must sometimes occasion. Hence, says Smith, "where the computed earnings of the greater part of manufacturers are nearly upon a level with the day-wages of common labourers, those of masons and bricklayers are generally from a half more to double those wages. Where common labourers earn four and five shillings a week, masons and bricklayers frequently earn seven and eight; and where the former earn nine or ten, as in London, the latter commonly earn fifteen and eighteen." (*Wealth of Nations*, p. 47.)

But these variations, instead of being inconsistent with the principle we have been endeavouring to establish, plainly result from it. Wages are not equal when each workman earns the same number of shillings or of pence in a given space of time, but when each is paid in proportion to the severity of the labour he has to perform, the degree of previous education and of skill that it requires, and the other causes of variation. So long, indeed, as competition is allowed to operate without let or hindrance of any kind, or as every one may employ himself as he pleases, the higgling of the market will always adjust the rate of wages, on the principle now mentioned; and it will, in reality, be nearly equal in different employments. If it were depressed in one department below the common level, labourers would leave it to go to others; and if it were raised above it, labourers would be attracted from the departments where wages were lower, until the increased supply had sunk them to their just level. A period of greater or less duration, according to the circumstances of the country at the time, is always required to bring about this equalization. But all theoretical inquiries, and such as have the establishment of principles for their object, either are or should be founded on periods of average duration; and when such is the case, we may always, without occasioning any error of consequence, assume that the wages earned in different employments are, all things considered, about equal.

Equality of the profits of the capital employed in different businesses.

In like manner, the profit accruing to the undertakers of different businesses varies proportionally to the greater or less risk, and other circumstances affecting the capital which is employed in them. It is obvious, indeed, that profits have not attained their proper level until they have been adjusted so as to balance these advantages and disadvantages. None would engage in unusually hazardous undertakings did the capital which they employ only yield the same profit that might be obtained by employing it in more secure businesses. None will voluntarily place their fortunes in situations of comparative danger. Extraordinary risk must be compensated. And hence the well-known distinction between *gross* and *nett* profit. Gross profit varies according to the risk, respectability, and agreeableness of different employments; whereas nett profit is the same, or nearly the same, in them all. A gunpowder manufacturer, for example, must obtain as much profit, over and above that which is obtained from the securest businesses, as will suffice to guarantee or *insure* his capital from the extraordinary risk to which it is exposed in a business of such extreme hazard. Were he to obtain *more* than this amount, additional capital would be attracted to the business; and were he to obtain *less*, capital would be withdrawn from it. The ever-acting principle of competition, or, which is the same thing, the self-interest of every individual, will not permit the wages or profits of any particular set of workmen or capitalists, taking all things into account, to continue either long below or long above the common and average rate of wages and profits obtained by those who are employed or have capital vested in other businesses. It is by this common standard that the wages and profits of particular businesses are always regulated; they never diverge considerably from it; they have a constant tendency to equalization; and may, in theoretical inquiries, be supposed, without occasioning any error of consequence, exactly to coincide.

The equality, or rather the constant tendency to equality, of the wages earned by the labourers, and of the profits derived from the capital employed at the same time in the various branches of industry, was pointed out by Harris, and also by Cantillon in his work entitled *The Analysis of Trade*, &c., published in 1759; but it was first fully demonstrated in the eighth, ninth, and tenth chapters of the first book of the *Wealth of Nations*. The establishment of this principle was one of the greatest services rendered by Adam Smith to the science. Nothing can be more convincing and satisfactory than his reasoning on this subject. The equality of wages and of profits has, since the publication of his work, been always assumed as admitted and incontestible.

Variations of demand and supply exert no permanent influence on price.

The equality of wages and profits once established, it is easy to see that variations in the demand and supply of commodities can exert no lasting influence over price. The cost of production, denominated by Smith and the Marquis Garnier necessary or natural price, is the ultimate regulator of the value of every commodity not subject to a monopoly, of which the quantity may be indefinitely increased by the application of fresh capital and labour to its production. The market price of such commodities and their cost do not always coincide; but they cannot for any considerable period be far separated, and have a constant tendency to equality. Commodities will not continue to be produced if they sell for *less* than the cost of their production; that is, for less than will repay the outlay upon them, including the ordinary rate of profit on the capital employed. This is a limit below which it is plain prices cannot be permanently reduced; and it is equally plain that were they for any considerable period to rise above it, additional capital would be attracted to the advantageous business, and the competition of the producers would lower prices.

A demand, to be effectual, must be such as will cover the expense of production. If it be insufficient to do this, it is insufficient to make commodities be produced and brought to market. A real demander must have the *power*, The will and the power to purchase necessary to constitute demand.

as well as the *will*, to purchase. A person with a sovereign in his pocket may be as anxious—nay, he may be ten times more anxious—to become the purchaser of a coach than of a hat. But while a sovereign will pay the expense of producing a hat, it will not pay the expense of producing a coach; and hence, though he may have the former, he cannot have the latter. Were such an improvement made in the art of coachmaking as should enable coaches to be manufactured as cheaply as hats, then a sovereign would buy a coach as easily as it now buys a hat. The demand for any particular commodity may become ten or twenty times more extensive, or it may decline in the same proportion; but if the cost of its production continue the same, its price will not permanently vary. If, for example, the demand for hats were suddenly doubled, their price would rise, and the hatters would make large profits; but this rise would only be of very limited duration; for the large profits, by attracting additional capital to the hat trade, would make an increased supply of hats be speedily brought to market; and if no variation took place in the cost of their production, their price would sink to its former level. Suppose, on the other hand, that the demand for hats is increased fivefold, and that the cost of their production is diminished in the same proportion: we should, notwithstanding the increased demand, be able in a short while to buy a hat for the fifth part of what it now costs. Again, suppose the demand for hats to decline, and the cost of producing them to increase, the price would, notwithstanding the diminished demand, gradually rise till it had reached the point at which it would yield the hatters the ordinary rate of profit on their capital. It is admitted that variations of demand and supply occasion temporary variations of price. But it is essential to observe that these variations are only temporary. The cost of production is the grand regulator of price—the centre of all those transitory and evanescent oscillations on the one side and the other; and wherever industry is free, the competition of the producers will always elevate or sink prices to this level.

ost of pro- uction the egulating rinciple f price.

In branches of industry, such as agriculture, which are liable to be seriously affected by variations of the seasons, and from which capital cannot be easily withdrawn, there is a longer interval than in others before the market price of produce and the cost of its production are equalized. But such an equalization is sure to be brought about in the end. No farmer, and no producer of any description, will continue to bring corn, cattle, and other products to market, unless they sell for a price sufficient to pay the expense of their production, including the common and average rate of profit on the capital employed.[1] An excess of supply occasionally depresses the prices of corn and other farm produce below this level; and the occupiers of land are in consequence involved in difficulties; but such gluts do not continue. The cultivators of the worst soils are driven from their employment; a smaller supply is in consequence brought to market; and prices are adjusted so as to yield customary profits to the agriculturists who continue to prosecute their business. The interest of the cultivators will not permit prices to be permanently depressed below this level; and the interest of the public will not permit them to be permanently raised above it; for if they were raised above it, the cultivators would gain more than the common and average rate of profit, and capital would of course be attracted to agriculture, and would continue flowing in that direction until the equilibrium of profit had been restored—that is, as will be afterwards seen, until the price of agricultural produce had fallen to such a sum as would yield ordinary profits to the occupiers of the worst soils in cultivation, or the improvers of the best. This is the point at which *average* prices continue stationary, or about which market prices oscillate, until the cost of production increase or diminish. Were any great discovery made in agriculture—such, for instance, as would reduce the cost of cultivation a half, the price of agricultural produce would speedily fall in the same proportion, and it would continue to sell at that reduced rate till the stimulus which this fall would give to population, and the consequently greater demand for supplies of food, forced recourse to soils of less fertility. Whenever this took place, prices would again rise, unless the influence of the decreased fertility of the land were countervailed by some new improvement. Why is the price of corn almost invariably higher in England than in Russia and Poland? Is it not because of the greater cost of its production in this country?

Reason why gold is more valuable than silver.

A pound-weight of gold is at present worth about *fourteen* or *fifteen* pounds of silver. It cannot, however, be said that this is a consequence of the demand for gold being greater than that for silver, the reverse being the fact. Neither can it be said to be occasioned by an absolute scarcity of gold; for those who choose to pay a sufficient price for it may obtain it in any quantity they please. The cause of the difference in the price of the two metals consists entirely in the circumstance of its costing about *fourteen* or *fifteen* times as much to produce a pound of gold as to produce a pound of silver. That this is the case, is plain from the admitted fact, that the producers of gold do not gain any greater profit than the producers of silver, iron, lead, or any other metal. They have no monopoly of the business. Every one may go or send capital to California and Australia, and become a producer of gold; and wherever this is the case, competition will always make the product be sold at such a price as will pay the expenses of its production, and no more. Were a gold-mine discovered of equal productiveness with the silver-mines, the production of gold would immediately become the most advantageous of all businesses; an immense supply of that metal would in consequence be thrown upon the market, and its price would be gradually reduced to the same level as silver.

Reason why cottons have declined in price.

In further illustration of this principle, take the case of cottons. None can deny that the demand for them has been prodigiously augmented within the last ninety or a hundred years; and yet their price, instead of increasing, as it should have done had the popular theory of demand and supply been well founded, has been constantly and rapidly diminishing. If it be said that this is a consequence of the supply of cottons having augmented in a still greater ratio than the demand, we answer that this is not enough to explain the fall of price. The supply would not have been brought to market had not the diminution of prices, which has been constantly going on since the invention of spinning-jennies in 1767, been balanced by an equal diminution of their cost. It is to this principle — to the vastly increased facility of production, occasioned by the stupendous inventions and discoveries of Hargreaves, Watt, Arkwright, Crompton, and others—that the lower price and increased demand for cottons are wholly owing. Their extraordinary cheapness has brought them within reach of all classes; and enabled the poorest individuals to clothe themselves in a dress which, at the accession of George III., was fully as expensive as silk.

A like reduction of price, though seldom to the same extent, has been occasioned by the introduction of improved machinery and processes into most departments of manufacturing industry. And we may take this opportunity of observing, that this circumstance shows the error of those who estimate the condition of the labouring classes by comparing their wages with the price of corn; and who contend, if the former have not increased as much as the latter, that their condition has deteriorated. But this conclusion is not necessarily true, unless these classes subsisted on corn only, which, as everybody knows, is not the case. Other articles as well as bread enter largely into their food; and they must in addition be clothed, housed, and supplied with fuel, while they generally also have some command over luxuries. Hence it is apparent, that though wages should not have done more than preserve their former relation to corn, or should even have declined as compared with it, the condition of the labourers may, notwithstanding, have been very materially improved; inasmuch as what they have not gained or lost in corn, they may have more than gained in their greater command over the many other things required for their subsistence and wellbeing. And it would be easy to show that such has been the case, though not to the extent that might be wished for, here and in most other countries. But to return—

---

[1] Some of the advocates of the agricultural interest have represented this as one of the "dangerous dogmas" of the Scotch Economists! But it can boast of a much more remote origin:—"*Nemo enim sanus*," says Varro, "*debet velle impensam ac sumptum facere in culturam, si videt non posse refici.*" (*De Re Rustica*, lib. i., § 2.)

Competition of the producers in a civilized society will always sink prices to the cost of production.

If a set of men were brought together from various countries, ignorant of each other's wants, and of the labour and expense necessary to produce the commodities which each possesses, these would be bought and sold according to the wants and fancies of the parties. In such circumstances, a pound of gold might be given for a pound of iron, and a gallon of wine for a gallon of small beer. As soon, however, as a commercial intercourse is established, and as the wants of society and the powers of production come to be well and generally known, an end is put to this method of bartering. Thousands of sellers then enter the market; and when such is the case, it is no longer possible to sell a pound of gold for a pound of iron; and why? because the producers of iron will undersell each other until they have, by their competition, reduced its price to such a sum as will suffice to pay the expense of its production. This, in every advanced society, is the pivot on which exchangeable value always turns. A civilized man may obtain articles from a savage, in exchange for toys or trinkets which it cost infinitely less to produce; but if he try to obtain the same advantage over his own countrymen, a very short experience will satisfy him that they are quite as clear-sighted and attentive to their own interests as he is.

Thus, then, it appears that no variation of demand, unaccompanied by a variation in the cost of production, has any lasting influence over price. If the cost of production be diminished, price will equally decline, though the demand should be increased to any conceivable extent. If the cost of production be increased, price will equally rise, though the demand should sink to the lowest possible limit.

Influence of monopolies.

It must always be remembered that this reasoning applies only to those commodities on which competition is allowed to operate without restraint, and whose quantity may be indefinitely increased by the application of fresh capital and industry to their production. When an individual, or class of individuals, obtains the exclusive privilege of manufacturing certain species of goods, the principle of competition is suspended with respect to them, and their price depends on the proportion in which they are brought to market compared with the demand. If monopolists supplied the market liberally, or kept it as fully stocked as it would be under a free system, their commodities would sell at their natural price, and the monopoly would have no disadvantage other than the exclusion of the public from an employment which every one should have leave to carry on. In point of fact, however, the market is never fully supplied with monopolized commodities. Producers universally endeavour to obtain the highest prices for their commodities; and when they are protected by a monopoly against being undersold by others, they either keep the market understocked, or supply it with inferior articles, or both. Under such circumstances, the prices of articles which cannot be easily smuggled from abroad, or clandestinely produced at home, may be elevated to the highest point to which the competition of the buyers can raise them; and may in consequence amount to five, ten, or twenty times the sum they would fetch were competition permitted to operate in their production. The *will* and *power* of the purchasers to offer a high price forms the only limit to the rapacity of monopolists.

Besides the articles produced under artificial monopolies, there is another class whose quantity cannot be increased by human industry, and whose price is not therefore dependent on the cost of production. Ancient statues, vases, and gems, the pictures of the great masters, some species of wines produced in limited quantities from soils of a particular quality and exposure, and a few other articles, come under this description. As their supply cannot be increased, their price varies inversely as the demand, and is totally unaffected by anything else.

It must also be understood, in saying that the cost of production is the regulating principle of value, that the statement applies to those articles only, the demand for which is sufficient to pay this cost, or to make them be produced. When corn falls or rises in price because of a good or a bad harvest, or black cloth or silk rises or falls because of the occurrence of a public mourning or a rejoicing, everybody is aware that the disturbance is temporary only, and that prices will be speedily adjusted to their common and ordinary level. But when, owing to a change of fashion or other cause, the demand for furniture, books, prints, and articles of a durable description, falls considerably off, their price sinks permanently below the cost of their production. The latter, indeed, has no influence over the price of articles which have ceased to be in efficient demand. Some half dozen or dozen individuals may be anxious to procure copies of a book, or of an edition of a book, which has been long out of print. But as the demand of the parties would not suffice to defray the cost of reprinting the work, the stray copies that may occasionally cast up are sold for the highest price the buyers are disposed to offer, without their being affected in any degree by the original cost of the book, of which, indeed, they most probably know nothing. And supposing, on the other hand, that a considerable impression of a book has been thrown off, and that the anticipated demand for it has not been realized, it will in no very lengthened period come to be sold for a third or a fourth part, or less, of its cost. Hence when it is affirmed that, in the long run, the prices of commodities or services are determined by their cost, it is always to be remembered that the principle is limited to those products or services for which there is a demand considerable enough to make them be supplied. If such be not the case, their prices may continue sunk far below, though they cannot exceed, what it would take to bring them to market. Suppose that an article would cost 20s. for its production, but that, from its getting out of fashion, none will give more than some 15s. or 16s. for the quantities of it on hand: in such circumstances, no more of it will be produced, and its price will no longer be dependent in any degree on the sum required to furnish the market with fresh supplies. But articles of this description make a comparatively unimportant class. They have ceased to be produced; and for all practical purposes it is true to say that in periods of average duration the prices of products and services are determined by the cost of their production.

Average price always coincident with cost of production.

When a fall takes place in the price of a commodity which is in efficient demand, it cannot be said whether it be really advantageous until it be learned whether its cost has been equally diminished. If this be the case, the fall of price will not be disadvantageous to the producers, and will be permanent; but if this be not the case,—if the cost of production continue the same, or has not fallen in the same ratio as the price,—the fall must be injurious to the producers, and prices will in no very lengthened period attain to their former level. It is the same with a rise of prices. No rise can be permanent unless the cost of production be proportionally increased. If it remain stationary, or do not increase in a corresponding degree, prices will decline as soon as the ephemeral causes of enhancement have disappeared.

The extreme importance of having correct opinions respecting the regulating principle of price, and the discordant and erroneous opinions so very prevalent with regard to it, will, we hope, be deemed a sufficient apology for the length of the previous remarks, and for the insertion of the following paragraph from the *Histoire de la Monnaie* of the Marquis Garnier, in which the doctrine we have been endeavouring to establish is enforced with equal ability and eloquence.

Opinion of the Marquis Garnier.

"Mais les producteurs tendent continuellement à régler la quantité des productions sur la somme des demandes; ils ne resteront pas au-dessous de ce point, sans être tentés d'accroître la masse de leurs produits; et ils ne peuvent le dépasser sans s'exposer à perdre. Ces deux quantités, celle des produits et celle des demandes, s'efforcent donc à se mettre en équilibre l'une avec l'autre. Il existe donc un point de repos vers lequel elles gravitent chacune de son côté; un point qui est leur niveau, et c'est ce point qui constitue le *prix naturel* de la chose vénale. Quelle est la limite au-délà de laquelle le producteur ne peut porter la quantité de ses produits? C'est le prix naturel; car, s'il ne peut obténir ce prix pour tout son produit, il sera en perte. Quelle est la borne des demandes du consommateur? C'est le prix naturel; car il ne veut pas donner plus que l'équivalent de ce qu'il reçoit. Si, par une découverte, ou par un perfectionnement de l'industrie, le producteur est mis à même d'établir l'article sur lequel il s'exerce à moins de temps et de dépense, alors le prix naturel baissera, mais aussi la somme des demandes accroîtra dans une proportion pareille, parce que plus de consommateurs seront en état de payer ce prix naturel, moins élevé que l'ancien. Le prix naturel sera toujours, pour chaque chose vénale, la limite commune au-délà de laquelle la somme des demandes de cette chose et la quantité de sa production ne devront plus faire de progrès. Quand le prix courant est le prix naturel, le producteur et le consommateur se donnent réciproquement l'équivalent de ce qu'ils reçoivent. Quand le prix courant s'écarte du prix naturel, ou c'est la consommation qui souffre au profit de la production, ou c'est la production qui souffre au profit de la consommation. Cet état de souffrance ne peut durer, et de-là procèdent les variations du prix courant. Ces variations, que Smith a expliquées et analysées avec une si parfaite lucidité, ne sont autre chose que les efforts pour revenir au prix naturel. Tenter d'expliquer ces variations, sans reconnaître l'éxistence d'un prix naturel, ce serait vouloir expliquer les oscillations du pendule sans convenir de sa tendance vers un centre de gravitation; ce serait supposer un effort sans but et sans mobile; ce serait admettre le mouvement et nier le repos; enfin, en voyant les phénomènes du cours des fluides et de l'équilibre des solides, ce serait contester les lois du niveau et de la pesanteur. Si les choses vénales n'ont point de prix naturel, alors les mouvements de la circulation seront dirigés par une force aveugle et inconnue; les prix moyens ne seront plus que le résultat de chances purement fortuites; il n'y aura plus d'équivalent réel; les valeurs n'auront plus de mesure naturelle; l'économie politique ne pourra plus aspirer à être au rang des sciences, puisqu'elle manquera du caractère essentiel qui les constitue telles, et que les faits dont elle traite ne seront plus fondés sur les lois immuables de la nature." (Tome i., Introduction, p. 62.)

Having thus shown that the *cost of production* is the regulating principle of price, we shall now proceed to investigate the elements which enter into and constitute this cost in an advanced state of society, when rent is paid for land, and circulating and fixed capital employed to assist the labour of workmen. This is, of all others, the most important, as it is the most radical inquiry in that part of the science which treats of the distribution of wealth; and it is indeed impossible, without possessing accurate notions on this subject, to advance a single step without falling into errors. We shall begin by endeavouring to ascertain whether rent enters into the cost of production.

SECT. III.—*Nature, Origin, and Progress of Rent.—Not a Cause, but a Consequence, of the High Value of Raw Produce.—Does not enter into Price.—Distinction between Agriculture and Manufactures.—Practical Considerations.*[1]

Definition of rent.

Rent is properly "that portion of the produce of the earth which is paid by the occupier to the landlord for the use of the *natural and inherent* powers of the soil." If buildings have been erected on a farm, or if it have been inclosed, drained, or in any way improved, the sum which a farmer will pay to the landlord for its use will be composed not only of what is properly rent, but also of a remuneration for the use of the capital laid out on its improvement. In common language, these two sums are always confounded under the name of rent; but in an inquiry of this nature it is necessary to consider them as perfectly distinct. The laws by which rent and profits are regulated being totally different, those which govern the one cannot be ascertained if it be not considered separately from the other.

No rent paid on the first settling of any country.

On the first settling of any country abounding in large tracts of unappropriated land, no rent is paid; and for the obvious reason, that no person will pay rent for what may be procured in unlimited quantities for nothing. Thus, in New Zealand, where there is an ample supply of unappropriated land, it is certain that, until the best lands are cultivated, no such thing as rent will ever be heard of. Suppose, however, that tillage has been carried to this point, and that the increasing demand can, in the actual state of agriculture, be no longer supplied by the best lands; it is plain that either the increase of population must cease, or the inhabitants consent to pay such an additional price for raw produce as will enable the *second* quality of land to be cultivated. No advance short of this will procure them another bushel of corn; and competition will not, as will be immediately seen, allow them to pay more for it. They have therefore but one alternative. If they choose to pay a price sufficient to cover the expense of cultivating land of the second quality, they will obtain additional supplies; if they do not, they must want them.

---

[1] The theory of rent explained in this chapter was first promulgated and satisfactorily established in a tract on the Corn Laws, Edinburgh, 1777 (see pp. 45–47). The author of this original and most important theory, Dr James Anderson, was a native of Hermandston in Mid-Lothian, and subsequently editor of the *Bee* and other publications; in one of which (*Observations on Agriculture and Natural History*, &c., v., pp. 401–405) he gave a new exposition of his theory. But notwithstanding the clear and able manner in which he explained his doctrines, and their ingenuity and importance, they do not appear to have attracted the least attention, and seem to have been completely forgotten. So much so was this the case, that when Mr Malthus (*An Inquiry into the Nature and Progress of Rent*) and Sir Edward West (*Essay on the Application of Capital to Land*, by a Fellow of University College, Oxford) published tracts in 1815 explaining the nature and origin of rent, they were universally believed to be the authors of the theory. There is, we believe, no doubt as to their originality. Still, however, they were merely expositors of what had been clearly and ably explained about forty years previously to the publication of their pamphlets.

Origin of rent.

Suppose, now, that the consumers offer such a price as will pay the expense of producing corn on soils which, in return for the same expenditure as would have produced 100 quarters on lands of the *first quality*, will only yield 90 quarters; it is plain it will then be indifferent to a farmer whether he pay a rent of ten quarters for the first quality of land, or farms the second quality, which is unappropriated and open to him without paying any rent.

Progress of rent.

If the population went on increasing, lands which would yield only 80, 70, 60, 50, &c. quarters in return for the same expenditure that had obtained 100 quarters from the best lands, might be successively brought under cultivation. And when recourse had been had to these inferior lands, the rent of the higher qualities would plainly be equal to the difference, or the value of the difference, between their produce and the produce of the worst quality under cultivation. Suppose, for example, that the worst quality under cultivation yields 60 quarters, then the rent of the *first* quality will be 40 quarters, or $100 - 60$; the rent of the *second* quality would, in like manner, be equal to the difference between 90 and 60, or 30 quarters; the rent of the third quality to $80 - 60$, or 20 quarters, and so on. But it is material to remark, that the produce raised on the land last cultivated, or with the capital last applied to the soil, is always sold at its *necessary price*, or at that price which is just sufficient to yield the cultivators the common and average rate of profit, or, which is the same thing, to cover the cost of its production. If the price were above this level, then agriculture would be the best of all businesses, and tillage would be immediately extended; while, on the other hand, if the price were below it, capital would be withdrawn from the soil, and the poorer lands thrown out of cultivation. Under such circumstances, it is clear that no rent would enter into the price of the produce raised by means of the capital last applied to the soil. It is entirely made up of wages and profits. The proprietors of the superior lands obtain rent; but this is the result of their greater fertility. The demand cannot be supplied without cultivating inferior soils; and, to enable them to be cultivated, their produce must fetch such a price as will afford the ordinary rate of profit to their cultivators. This price will, however, yield a surplus, over and above the ordinary rate of profit, to the cultivators of the more fertile lands, and *this surplus is rent.*

An increase of rent is not, therefore, as is very generally supposed, occasioned by improvements in agriculture, or by an increase in the fertility of the soil. It results from the necessity of resorting, as population increases, to soils of a *decreasing* degree of fertility, and from the inability to apply capital indefinitely to the best land without a diminished return. Rent varies inversely as the amount of produce; that is, it increases when the produce of agricultural labour diminishes, and diminishes when the produce increases. That labour is best rewarded in countries like New Zealand, Indiana, and Minnesota, and generally in all situations in which no rent is paid, and the best lands only are cultivated.

A quarter of wheat may be raised in the Vale of Gloucester or the Carse of Gowrie, for perhaps a *fourth* or a *fifth* part of the expense necessary to raise it on the worst soils in cultivation in other parts of the kingdom. There cannot, however, be at the same time two or more prices for the same article in the same market. And it is hardly necessary to say, that unless the price of wheat be such as will indemnify the producers of the portion of the crop which is raised on the worst soils, they will cease bringing it to market, and the required supplies will not be obtained; and it is equally plain, that if its price exceed this sum, fresh capital will be applied to its production, and competition will eventually sink prices to their natural level,—that is, to a sum sufficient to afford ordinary profits to the growers of that portion of the required supply which is raised in the most unfavourable circumstances, and at the greatest expense. The cost of producing this portion determines the price of the rest. And hence it is indifferent to the consumers whether, in an advanced stage of society, the excess of return over the cost of production on the best lands belong to a non-resident landlord or an occupier. It must belong to the one or the other. Corn is not high because a rent is paid, but a rent is paid because corn is high—because the demand is such that it cannot be supplied without cultivating soils of a diminished degree of fertility as compared with the best. Suppose there is an effectual demand for ten millions of quarters, of which *one* million must be raised on lands that yield nothing but the ordinary rate of profit to their cultivators: it is clear that, though the rents payable by the cultivators of the superior lands were relinquished, that would be no boon to the cultivators of the inferior lands. It would not lessen their expenses; that is, it would not lessen the amount of capital and labour required to produce that portion of the necessary supply that is raised under the most unfavourable circumstances; and, unless it did this, it is impossible, supposing the demand not to decline, that it should lower prices. Although, therefore, landlords were to give up the whole of their rents, their ill-judged liberality would not cheapen anything. It would turn farmers into landlords, and landlords into beggars; but there its effect would stop. But the case is altogether different when the cost of production varies. If it be diminished, the competition of the producers never fails to sink prices in an equal degree; while, if it be increased, supplies will cease to be brought to market, unless the price rise to a corresponding level. In no case, therefore, whether the demand be great or small,—whether for a million or ten million quarters,—can the price of raw produce permanently exceed or fall below the cost of producing that portion of the necessary supply which is raised on the worst land, or with the last capital laid out on the soil.

Objections to this theory.

Various objections have been made to this theory. In the *first* place, it has been said that, though it may hold in a country like Australia, where land is not appropriated, yet that the worst land in civilized and appropriated countries, like England, always yields some small rent to the proprietor; and that therefore it cannot be said that the price of produce is, in such countries, determined by the cost of raising it on that quality of land which pays no rent.

It has been justly observed of this objection, that even were it well founded, it would not practically affect any of the conclusions we have endeavoured to establish. There are in England and Scotland thousands of acres of land which do not let for L.100; but to cultivate them would require an outlay of many thousands, and the rent would consequently bear so small a proportion to the expenses of production as to become altogether evanescent and inappreciable.

Land in every extensive country which yields no rent.

There can be no doubt, however, that there is in this, and most other extensive countries, a great deal of land which yields no rent. In the United States and Russia this is unquestionably the case; and yet no one presumes to say that the laws which regulate rent in these countries are different from those which regulate it in England and France. The poorest lands are always let in immense tracts. If it were attempted to let particular portions of these tracts separately, they would bring no rent; but they appear to yield rent, because, though rent is not paid for

Payment of rent on all soils not inconsistent with the principle that rent does not enter into price.

them, it is paid for the more fertile spots intermixed with them. But though it were true that every rood of land in Britain paid rent, it is easy to see that that payment would not affect the price of raw produce. The rent of a country consists of the difference, or the value of the difference, between the produce obtained from the capital first applied to the land and that which is last applied to it. It would, as already seen, be exactly the same thing to a cultivator whether he paid a rent of ten quarters for land yielding, with a certain outlay, a hundred quarters of corn, or employed the same capital in cultivating inferior land yielding only ninety quarters, for which he paid no rent. Were it possible always to obtain the same amount of produce for every equal additional capital applied to the superior soils, those of an inferior quality would never be cultivated. But the fact that, in the progress of society, new and less fertile land is always brought into cultivation, demonstrates that additional capital and labour cannot be indefinitely applied with the same advantage to the old land. The population of a particular country may be so dense, and the demand for agricultural produce so great, that every quality of land may actually yield rent; but it is indifferent if capital be employed on land which yields only the return of stock with its ordinary profits, whether it is employed on old or new land. Now, that there is a very large amount of capital employed in such a manner in this and every other country is abundantly certain. A farmer who rents a farm, besides employing on it as much capital as will, at the current prices, enable him to pay his rent, obtain average profits, and replace his stock previously to the expiration of his lease, will employ additional capital, if it will only replace itself, and afford ordinary profits. His employing this additional capital depends entirely on prices being such as will repay his expenses and profits; for he knows he will have no additional rent to pay. The true and universal theorem is, that if the last capital carried to agriculture yield more than the ordinary rate of profit, it will be increased till prices sink so as to yield that rate only; and that, in the event of their sinking so as to yield a less rate, the outlay of capital on the land will cease, and portions of it engaged in farming will be carried to other businesses, till prices and profits have been raised to their proper level. Hence, speaking generally, it appears that in every case, whether the last quality of land taken into cultivation yield rent or not, the last capital applied to the soil yields only ordinary profits; and consequently, the price of the produce which it yields, and which regulates the price of the rest, is totally unaffected by rent.

oes not

hat land-
ords will
llow far-
ers to oc-
py their
nds with-
t paying
nt.

It has, in the *second* place, been objected to this account of the nature and causes of rent, that it takes for granted that landlords in extensive countries permit the farmers of the worst lands to occupy them without paying any rent. But it is easy to see that this is a mistake. Raw produce is kept down to its necessary price by the competition of farmers, and not by that of landlords. Though there is a very wide difference, in extensive countries, between the best and worst soils, the gradation from the one to the other is gradual, and almost imperceptible. The best differ but little from those immediately inferior to them, and the worst from those immediately above them. And hence it is as impossible to show where the first quality ends and the second begins, or where the second ends and the third begins, as it is to point out the line of demarcation between the contiguous colours of the rainbow. Now, suppose that the numbers 1, 2, 3, 4, 5, 6, 7, &c., designate the different qualities of soil in an extensive country, and suppose that the effectual demand for raw produce is such as will afford the common and average rate of profit to those who cultivate land of the *fifth* degree of fertility, or that represented by No. 5: when such is the case, there can be no doubt that No. 5 will be cultivated; for, besides the peculiar attractions which agriculture possesses, it would be quite as advantageous to cultivate it as to engage in any other business. It would not, however, be more advantageous; for its produce would yield no surplus in the shape of rent. But suppose that a combination took place among the proprietors of Nos. 1, 2, 3, 4, and 5, to withhold a portion of their produce from market; and that, in consequence of this or any other cause, the price of corn is raised a little above the expense of its production on No. 5; in that case it is obvious that soils of the *very next* degree of fertility, or that portion of No. 6 which, in point of productive power, differs extremely little from No. 5, would be brought under cultivation, and the increased supply would infallibly sink prices to the level that would afford the average rate of profit, and no more, to the cultivators of No. 5, or of the poorest soils which the supply of the effectual demand renders it necessary to cultivate. It is quite the same, therefore, in so far as price is concerned, whether a country be appropriated or not. When it is appropriated, prices are kept down to their lowest limit by the competition of the landlords. And it is by the same principle,—the cost of producing the portion of the necessary supply which is raised under the most unfavourable circumstances,—that the price of raw produce is determined in England and France, and in New Holland and Minnesota.

Does not account both for a rise and fall of price in the same way.

But then it is said that this reasoning involves a contradiction; that it accounts for a rise and a fall of price in the same way, or by an extension of cultivation! In truth and reality, however, it does no such thing. The market price of corn will always be low where it is cheaply produced, as in Poland; and it will occasionally be low where it costs a great deal to produce it, when a redundant supply is brought to market. Suppose, as before, that the effectual demand for corn in Great Britain is such as will enable lands of the *fifth* degree of fertility to be cultivated; but that, owing to variable harvests, to injudicious encouragement held out by the legislature, the ardour of speculation, the miscalculation of farmers, or any other cause, lands of the *sixth* degree of fertility have been cultivated; the increased quantity of produce that must thus be thrown on the market will plainly depress prices to such an extent that, instead of yielding average profits to the cultivators of No. 6, they will not yield them to the cultivators of No. 5. But they will yield *more* to them than to the cultivators of No. 6. The latter, therefore, will be first driven from their business; and when they have retired, prices will rise, not indeed to such a height as to enable No. 6 to be cultivated, but so high as to enable the cultivators of No. 5 to continue their business; that is, as has been already shown, to such a sum as will enable the raisers of the last portion of the necessary supply to obtain the common and average rate of profit. Should the demand, instead of continuing stationary, increase so that it could not be supplied without cultivating Nos. 6 and 7, the price will rise in proportion to the increased expense of their cultivation. But to whatever extent the demand might increase, still, were such an improvement made in agriculture, or in the art of raising corn, as would enable the supply to be raised from No. 1 only, the price would infallibly fall to the sum that paid the expenses of its cultivators, and rent would entirely disappear.

Answer to the objection, that the best lands are not always first cultivated.

The intelligent trader will easily perceive, when it is said that superior lands are the first to be brought into cultivation, that the statement is not made absolutely, but with reference to the capacities of the cultivators. Lands endowed with a high degree of natural fertility are often, in thinly-peopled countries, either heavily timbered or so very wet as to be totally unfit for tillage; and wherever this is the case, cultivation is confined at first to open, dry, or down lands. The latter are, in fact, the most fertile which it is in the power of the inhabitants to cultivate. After population has become denser, and capital been accumulated, the neglected lands will most likely be cleared, drained, and brought into tillage. But it by no means follows, though they may yield a greater amount of produce per acre, that they are therefore more fertile than those first cultivated. The presumption, indeed, is all the other way. Fertility, it is to be remembered, does not depend merely on quantities of produce, but on the quantities compared with the outlay required for their production; so that, if an acre of a certain description of land produce 50 bushels of wheat to an outlay of L.100, and an acre of a different description produce 35 or 40 bushels to an outlay of L.50, the latter is by far the more fertile of the two; and when both qualities of land are cultivated, the last will bring a large rent. It is, indeed, absurd to suppose that men will resort in preference to what is really inferior land. Whatever Mr Carey[1] or any one else may say to the contrary, such folly must be of rare occurrence, and it may be safely laid down that those lands which, all things considered, are the most fertile, will be first brought into cultivation.

Distinction between agriculture and manufactures and commerce.

Tendency of manufactured products to fall in price.

This analysis of the nature and causes of rent discovers a fundamental distinction between agricultural and commercial and manufacturing industry. In manufactures, the worst machinery is first set in motion; its powers are progressively improved by new inventions; and it is rendered capable of yielding a greater amount of produce with the same expense. And as no limits can be assigned to the quantity of improved machinery that may be introduced; as a million of steam-engines may be constructed for the same, or rather for a less, proportional expense than would be required for the construction of one; the competition of capitalists never fails to reduce the price of manufactured commodities to the sum which the least expensive method of production necessarily requires for their production.

Tendency of agricultural products to rise in price.

In agriculture, on the contrary, the best machinery, that is, the *best soils*, are first brought under cultivation, and recourse is afterwards had to inferior soils, requiring a greater expenditure of capital and labour to produce the same supplies. The improvements in the construction of farming implements, and the meliorations in agricultural management, which occasionally occur, countervail to a greater or less extent the decreasing fertility of the soil. But the fall of price, which is permanent in manufactures, is only temporary in agriculture. A fall in the price of raw produce, by enabling every class to obtain greater quantities than before for their products or their labour, raises the rate of profit, and leads of course to an increased accumulation of capital; and this necessarily leads to a greater demand for labour, to higher wages, to an increased population, and consequently to a further demand for raw produce and an extended cultivation. Agricultural improvements check for a while the necessity of having recourse to inferior soils and the rise of rents; but the check cannot be lasting. The stimulus which they at the same time give to improvement and population is sure in the end to raise prices, and, by forcing recourse to poor lands, to raise rents.

Earth compared by Malthus to a series of machines endowed with different productive powers.

Malthus, in illustrating this important distinction between agricultural and manufacturing industry, set the doctrine of rent in a striking point of view. "The earth," he observes, "has been sometimes compared to a vast machine, presented by nature to man for the production of food and raw materials; but to make the resemblance more just, as far as they admit of comparison, we should consider the soil as a present to man of a great number of machines, all susceptible of continued improvement by the application of capital to them, but yet of very different original qualities and powers.

"This great inequality in the powers of the machinery employed in procuring raw produce, forms one of the most remarkable features which distinguishes the machinery of the land from the machinery employed in manufactures.

"When a machine in manufactures is invented which will produce more finished work with less labour and capital than before, if there be no patent, or as soon as the patent is over, a sufficient number of such machines may be made to supply the whole demand, and to supersede entirely the use of all the old machinery. The natural consequence is, that the price is reduced to the price of production from the best machinery; and if the price were to be depressed lower, the whole of the commodity would be withdrawn from the market.

"The machines which produce corn and raw materials, on the contrary, are the gifts of nature, not the works of man; and we find by experience that these gifts have very different qualities and powers. The most fertile lands of a country, those which, like the best machinery in manufactures, yield the greatest products with the least labour and capital, are never found sufficient to supply the effective demand of an increasing population. The price of raw produce, therefore, naturally rises till it becomes sufficiently high to pay the cost of raising it with inferior machines, and by a more expensive process; and as there cannot be two prices for corn of the same quality, all the other machines, the working of which requires less capital compared with the produce, must *yield rents in proportion to their goodness.*

"Every extensive country may thus be considered as possessing a gradation of machines for the production of corn and raw materials, including in this gradation not only all the various qualities of poor land, of which every large territory has generally an abundance, but the inferior machinery which may be said to be employed when good land is further and further forced for additional produce. As the price of raw produce continues to rise, these inferior machines are successively called into action; and as the price of raw produce continues to fall, they are successively thrown out of action. The illustration here used serves to show at once the necessity of the actual price of corn to the actual produce, and the different effect which would attend a great reduction in the price of any particular manufacture, and a great reduction in the price of raw produce.

"I have no hesitation, then, in affirming, that the reason why the real price of corn is higher, and continually rising, in countries which are already rich, and still advancing in prosperity and population, is to be found in the necessity of resorting constantly to poorer land,—to machines which require a greater expenditure to work them,—and which consequently occasion each fresh addition to the raw produce of the country to be purchased at a greater cost:—in short, it is to be found in the important truth, that corn is sold at the price necessary to yield the actual supply; and that, as the production of this supply becomes more and more difficult, the price rises in proportion.

"I hope to be excused for having dwelt so long, and presented to the reader in various forms, the doctrine that corn, in reference to the *quantity actually produced*, is sold at its necessary price, like manufactures, because I consider it as a truth of the highest importance, which has been entirely overlooked by the economists, by Dr Smith, and all those writers who have represented raw produce as selling always at a monopoly price." (*Inquiry into the Nature and Progress of Rent*, p. 37.)

It appears, therefore, that in the earliest stages of society, and when only the best lands are cultivated, no rent is paid. The landlords, as such, do not begin to share in the produce of the soil until it becomes necessary to cultivate lands of an inferior degree of fertility, or to apply capital to the superior lands with a diminished return. Whenever this is the case, rent begins to be paid; and it continues to increase according as cultivation is extended over poorer soils, and diminishes according as they are thrown out of cultivation. Rent therefore depends exclusively on the extension of tillage. It is high where tillage is widely extended over inferior lands, and low where it is confined to the superior descriptions only. But in no case does rent enter into price; for the price of that portion of the required produce which is raised on the poorest lands, or with the capital last applied to the soil, determines the price of the whole, and that portion yields no surplus above the common and average rate of profit.

---

[1] An American, the author of a great many crude and indigested economical works.

nfluence f situation n rent.

In estimating rent, difference of situation has in many cases an influence similar to difference of fertility. Lands that are situated in the immediate vicinity of a large town uniformly bring higher rents than those that are situated some twelve, twenty, or thirty miles off, provided the latter have no other market. The town affords a ready outlet for a great variety of articles for which there is little or no demand in the country; and though each of these may be trifling, yet their aggregate amount is usually considerable. Inasmuch, too, as the cost of conveying articles varies with the distance and difficulty of the roads along which they have to be carried, the less charge on those raised in the vicinity of markets enables their growers to pay a proportionally greater amount of rent. To preserve this advantage, the landlords of the counties contiguous to the metropolis opposed in 1767 the extension of turnpike roads to those situated at greater distances. But though their selfish policy had been in so far successful, it would not have gained their object unless they had been able to get obstructions laid on the navigation of the Thames. And had these also been imposed, the result would have been, that by checking or preventing the growth of the city, they would not have realized a tenth part of the advantage from their monopoly that they now reap from the all but boundless market which it affords for all the products, whether of the nearest or most distant parts of the empire.

nstituent rts of nt, popu- ly so led.

To prevent misapprehensions, it may be as well, perhaps, to repeat that the theory of rent which has now been explained refers only to the sums paid for the use of the soil, without including those which are also paid under the name of rent for the services rendered by the capital that has been expended upon the soil. But in all tillage farms this latter portion makes a part, and often a very large part, of what is popularly called rent. Even in the best farms the payments on account of houses, fences, and roads are usually far from being an inconsiderable portion of the rent; while the rent of such naturally inferior farms as have been highly improved, consists almost entirely of the profit of the outlay upon them. Hence the necessity, if we would avoid falling into the most serious errors, of distinguishing between the different constituents of the gross rent paid for lands. It may be supposed, perhaps, that if two farms let for the same sum—as L.500 or L.1000 a year each—that they are therefore of the same value; and this would be the case if they were of the same or nearly the same quality. But if they be of different qualities, the one consisting of fine and the other of poor but highly-improved land, they would, if offered for sale, bring very different prices. For, as the rent of the superior farm consists mainly of a payment for the use of the natural powers of the soil, it may be considered as a perennial source of income; whereas the rent of the inferior farm, being derived from improvements which wear out and require to be renewed, is of comparatively transient duration, and worth so much less.

The circumstances now mentioned ought always to be taken into account when taxes and other burdens are imposed on land. And the all but insuperable difficulty of making proper allowances for their influence has been a main cause of the unjust and pernicious operation of such taxes.

It may further be observed, that the theory of rent now explained is practically applicable only to countries in something like the same condition as England; that is, to countries in which the tenants and occupiers of land farm it to realize ordinary profits on their capital, under a system of free competition. But in many countries of Europe the occupiers have little or no capital except what is furnished to them by the landlords, the produce being divided between them in certain proportions, of which the least generally goes to the tenant. In India and the greater number of eastern countries the sovereign is held to be the proprietor of all the lands of the empire; and the exorbitant amount of the land-tax or rent imposed on the cultivators, added to the impossibility of its being fairly assessed, make it a powerful obstacle to improvement, and a fruitful source of barbarism. But it is enough to have indicated the nature and importance of some of the practical questions connected with the theory of rent; to enter further into their enumeration or discussion would be inconsistent with the objects and limits of this article.

It being thus established that the circumstance of land being appropriated, and rent paid to the landlords, does not affect the price of commodities, or the principle which determined their exchangeable value in the earliest stages of society, we have next to inquire into the effects of the accumulation and employment of capital, and of the rise and fall of wages on the value of commodities.

Sect. IV.—*Influence of the Accumulation and Employment of Capital, and of Fluctuations in the Rate of Wages on Exchangeable Value.*

Value of commodities regulated by the amount of immediate labour and capital expended in their production.

It will be remembered that the quantity of labour required to produce commodities and bring them to market, formed, in the earliest stages of society, and before capital was accumulated, the standard by which their exchangeable value was regulated. But capital is merely the accumulated produce of *anterior labour;* and when it is employed in the production of commodities, their value is not determined by the quantity of immediate labour only, but by the total quantity of immediate and accumulated labour or capital necessarily laid out on them. Suppose that an individual can by a day's labour, without the assistance of capital, kill a deer; but that it requires a day's labour to construct the weapons necessary to enable him to kill a beaver, and another day's labour to kill it; it is evident, supposing the weapons to have been rendered useless in killing the beaver, that it took as much labour to kill the latter as was required to kill two deer, and the beaver would therefore be worth the two deer. The durability of the weapons, or capital of the beaver hunter, is obviously an element of the greatest importance in estimating the value of the animals he has killed. Had the weapons been more durable than has been supposed,—had they served, for example, to kill twenty beavers instead of one, then it is plain the quantity of labour required to kill a beaver would only have been one twentieth part, or five per cent., more than that required to kill a deer, and the animals would of course have been exchanged in that proportion. With every extension of the duration of the weapons, the value of the deer and the beaver would be brought still nearer to equality.

It appears, therefore, inasmuch as capital is nothing but the produce of anterior labour, that its accumulation and employment is consistent with, or rather is embodied in, the proposition, that the value of commodities depends on the labour required for their production. A commodity may be altogether produced by capital, without the co-operation of any immediate labour; and if so, its value will be determined by the quantity of capital, that is, of antecedent labour expended on its production: or it may be partly produced by capital, and partly by immediate labour, and then its value will be proportioned to the sum of the two; or, which is the same thing, to the total amount of labour bestowed upon it. The principles now laid down are almost self-evident, and have been generally assented to; but a considerable difference of opinion is entertained respecting the influence which the employment of workmen by capitalists, and the fluctuations in their wages, have over value.

The employment of workmen by capitalists does not raise the price of commodities.

It does not, however, seem that there is much room for these differences. Suppose that a certain quantity of goods, say twenty pairs of stockings, manufactured by independent workmen, freely exchange for forty pairs of gloves, also manufactured by independent workmen: they would continue to be exchanged on this footing, provided the quantity of labour required for their production continued unchanged, though the workmen should be employed by master manufacturers. In the first case, it is true, as Adam Smith has observed, that the goods produced by the workmen belong wholly to themselves; and that, in the second case, they have to share them with others. But it must be recollected, that in the first case the capital made use of in their production also belonged to the workmen, and that in the latter case it has been supplied to them by others. The question then comes to be,—Does the circumstance of labourers voluntarily agreeing to give a portion of the commodities produced by them as an *equivalent* or compensation for the use of capital supplied to them by others, afford any ground for raising the price of such commodities? It is evident it does not. The profits of stock are only another name for the wages of accumulated labour. They enter into the price of every commodity in the production of which any portion of capital has been expended. But whether the capital belong to the labourer, or is furnished to him by another, is obviously of no consequence. When the capital does not belong to the labourer, the commodities he produces are divided into *two* portions, whereof one is the return for the immediate labour, and the other for the capital or accumulated labour required for their production. But the value of the produce is the same, into how many portions soever it may be divided. A shoemaker who manufactures shoes on his own account obtains the same profits on their sale that would accrue to the master-shoemaker who should employ him as a workman. He must have capital to maintain himself and his family until his shoes are disposed of, to provide himself with a workshop and tools, to advance money to the tanner to pay his leather, and to meet other outgoings. If he did not, exclusive of the ordinary wages of labour, realise a profit or a return for his capital equal to the profit obtained by the master-shoemaker, it would be for his advantage to lend his capital to the latter, and to work on his account: and it is plain, inasmuch as his shoes would not sell for a higher price than those of the capitalist, that he could not realise a greater profit. It is immaterial, therefore, whether the accumulated labour or capital, and the immediate labour employed in the production of commodities, be furnished by the same or by different parties. It is by the total quantity of labour necessarily expended upon them, and not by the channels through which it is supplied, that their value is determined.

It now only remains to trace the influence of fluctuations of wages on price. When this is done, the subject will be exhausted.

To simplify this inquiry, we shall divide it into two branches. We shall inquire, *first*, whether fluctuations of wages have any, and if any, what effects, on the value of commodities produced by the aid of capitals of equal degrees of durability; and *second*, whether these fluctuations have any, and if any, what effects, when the capitals employed are of unequal degrees of durability.

Effect of fluctuations in the rate of wages on exchangeable value:—1. Effect of these fluctuations when the capitals employed in production are of the *same* degree of durability.

I. When all classes of producers employ fixed or circulating capitals of the same degree of durability, they must be all equally affected by a rise or fall of wages. This principle is admitted by every one, and is indeed self-evident. But when such is the case, it is plainly impossible that a rise or fall of wages should occasion any variation in the value of commodities. To revert to our former example: let it be supposed that wages, at the rate of a shilling a day, were paid by the stocking manufacturer, a pair of whose stockings exchanged for two pairs of gloves, and that, from some cause or other, the wages of his workpeople have been doubled, or raised to two shillings; the question is, will he now obtain a greater quantity of gloves for his stockings? It is obvious he will not. He cannot urge the fact of his having to pay higher wages as a reason why the glove manufacturer should give him more gloves in exchange for stockings; for the latter would have it in his power to reply, that the same rise of wages affected him to precisely the same extent! If, therefore, one pair of stockings were previously worth two pairs of gloves, they would continue to preserve that relation so long as the quantities of labour required for their production did not vary, whatever might be the fluctuation of wages,—whether they fell to a sixpence, or rose to five shillings a day. Even if the price of commodities rose, which it does not, when wages rise, that would be no advantage to the producers. Commodities are always bought by commodities or by labour. Of what consequence, then, would it be to a capitalist to sell, when wages rose, his commodities at an equal advance, seeing that he, in his turn, would be obliged to give so much more for every article which he has to purchase? Were wages to rise ten per cent., a producer—a hatter for example—would be in precisely the same condition whether he sold his hats for ten per cent. advance, and gave an additional ten per cent., as he would be obliged to do, for his food, shoes, clothes, &c., &c., or sold his hats at their former price, and bought the articles for which he has occasion at the prices he formerly paid for them.

In order farther to illustrate this principle, we may be allowed to make a supposition, which, though it cannot actually take place, will serve to set this doctrine in a clearer point of view. Should the quantities of labour required for the production of all sorts of commodities be increased in exactly the same proportion, their exchangeable values would plainly remain unaltered. Their cost would, however, be augmented. A bushel of corn would not then exchange for a greater quantity of muslins or of broad cloth than it did before the increased expense of its production; but each would be the produce of more than the former quantity of labour. Under such circumstances, the prices of commodities would remain stationary, while the wealth and comforts of the society would be materially diminished. Every person would have to make greater exertions to obtain a given supply of any one commodity; but as the expense of producing *all* commodities is, by the supposition, equally increased, it would not be necessary to make any greater exertions to obtain one than another, and their values, as compared with each other, would be totally unaffected.

In these statements it is taken for granted that the value of money has been invariable. But if it become either more or less valuable, then undoubtedly the rate of wages and the prices of commodities will both vary. They will do so, however, not because the labourer gets a greater or less amount of wages, but because the value of the commodity or standard in which wages and prices are estimated has varied. Wages, though most commonly paid in money, really consist of a portion of the produce of industry. And hence, to avoid falling into endless mistakes, it is best, in theoretical investigations with respect to value, to consider wages as constituting a certain share of the produce of industry; as being really invariable, so long as this share continues unchanged; and as having really risen when it is increased, and really fallen when it is diminished.

The mistaking of fluctuations in the rate of money wages for fluctuations in the rate of real wages, has been the source of much error and misapprehension. A man whose wages are one shilling a day, must get two shillings to keep them at the same level, should the value of money decline a half; and the hat which now sells for ten shillings must then, for the same reason, sell for twenty shillings. It is obviously wrong to call this a real rise, either of wages or prices; this, however, is what is generally done. The manufacturer who gives sixpence a day more to his men, and who sells his goods at a proportionally higher price because of a fall in the value of money, rarely suspects that there has been any such fall, and generally concludes that the rise of wages has been the cause of the rise of prices, overlooking entirely the real cause of the rise of both—the decline in the value of the money or commodity in which wages and prices are rated.

It has been seen that a general and equal increase of the labour required for the production of commodities does not alter their relation to one another; and it is consequently obvious that this relation cannot be altered by a general and equal increase of the wages paid for that labour. Fluctuations in the rate of wages affect the proportion in which the produce of industry, under deduction of rent, is divided between capitalists and labourers—diminishing the proportion belonging to the capitalists when they rise, and increasing it when they fall. But as these changes in the distribution of commodities neither add to nor take from the quantity of labour required to produce them and bring them to market, they neither affect their real nor exchangeable value.

. Effect of hese fluctuations hen the apitals mployed n production are of *ifferent* degrees of urability.

II. We have seen by the investigation under the preceding head, that, where the capitals employed in production are of *equal* degrees of durability, fluctuations of wages affect all classes of producers to the same extent, and have, therefore, no influence on the value or price of commodities. But when the capitals employed are of *different* degrees of durability, this is not the case. Fluctuations in the rate of wages do not, in such cases, equally affect all producers, and the natural equilibrium of profit cannot be maintained without a variation in the value of their products. To illustrate this, let it be supposed that a quantity of goods, the produce of fixed capital or machinery fitted to last many years, freely exchanges for a quantity of other goods entirely produced by manual labour. It is plain they would not be exchanged on this footing after a rise or fall of wages; for the proprietor of the machinery would be very little affected by such fluctuations, whereas they would very seriously affect the proprietor of the goods produced by manual labour. And, therefore, when wages fluctuate, the values of the goods produced by capitals of different degrees of durability must also fluctuate —that is, they must be adjusted so that they may continue to yield the same average rate of profit. Let us endeavour to trace the mode in which this adjustment is effected.

The arguments now brought forward, to show that fluctuations in the rate of wages do not affect the value of commodities produced by capitals of the same durability, were first advanced by Mr Ricardo. He, too, was the first who endeavoured to analyse and discover the influence of fluctuations in the rate of wages on commodities, when the capitals employed in their production were *not* of the same degree of durability. The results of his researches in this more difficult branch of the science were still more important, and more at variance with the previously received opinions of economists. Ricardo not only showed that it was impossible for any rise of wages to raise the price of *all* commodities; but he also showed, that in many cases a rise of wages led to a *fall* of prices, and a fall of wages to a *rise* of prices! The novelty of these opinions, and the talent and ingenuity with which they were supported, immediately recommended them to general notice, and the repeated examinations to which they have since been subjected have confirmed their truth, and set them in a clearer point of view.

If a rise of wages lowers profits, it must lower the value of goods chiefly produced by fixed capital or machinery.

Suppose a manufacturer has a machine worth L.20,000, of a high degree of durability, and which can, without any, or with but little, manual labour, produce commodities: If profits were at ten per cent., the commodities annually produced by this machine would sell for L.2000, together with a small addition to replace its wear and tear.[1] Now, it is clear, that when profits either rise or fall, the price of the goods produced by this machine will also rise or fall. If profits were to rise to fifteen per cent., the goods produced by the machine would, in order that its owner may obtain the same profit with other capitalists, rise to L.3000; and if, on the other hand, profits fell to five per cent., the goods would, for the same reason, fall to L.1000. If, therefore, it be true that a rise of wages reduces the rate of profits, it will also reduce the price of such commodities as are chiefly produced by machinery, or fixed capital of a considerable degree of durability, or by circulating capital returnable at distant periods, and *vice versa.* And it is not difficult to see that this is really the case, and that, in point of fact, profits, supposing other things to continue the same, fall when wages rise, and rise when wages fall.

It results from what has been previously stated, that to whatever extent wages might rise, no class of producers, whether their capitals were returnable in a day, a week, or any other period, would obtain any larger share of the commodities produced by others of the *same class,*—that is, whose capitals were returnable in *equal periods* with their own. Suppose wages rise ten or twenty per cent., that would not enable a manufacturer whose capital was returnable in a month, or in twelve months, to obtain in exchange for his goods, any greater portion of the goods of such manufacturers as were affected to the same extent as himself by the rise of wages,—that is, whose capitals were returnable in the same period as his own. This is as impossible as it is to change the relation of numbers by multiplying or dividing them by the same number; and therefore it is not true that a rise of wages will raise the price of any one commodity, as compared with all other commodities.

But if a rise of wages cannot do this, it is demonstrably certain it must lower profits. Suppose that the numbers 1, 2, 3, 4, 5, 6, 7, 8, 9, and 10, represent capitals of corresponding degrees of durability. When wages fluctuate, the proprietors of the least durable capitals, numbers 1, 2, 3, 4, and 5, are plainly more affected thereby than the proprietors of the more durable capitals, numbers 6, 7, 8, 9, and 10. Suppose, now, that wages rise, and let us endeavour to discover what would be the effect of this rise on the holder of a capital of the *tenth* degree of durability. It has been already seen that, whatever might be the amount of the rise—whether it were one, ten, or a hundred per cent.—the holder of such capital would not get any additional quantity of the commodities belonging to other producers whose capitals were also of the *tenth* degree of durability; and in so far, therefore, as this class of commodities is concerned, profits will be reduced to the precise extent that wages have risen. But the holders of the other capitals are all of them *more* affected by the rise of wages than the holders of No. 10; and if we took any one of them as a standard by which to measure profits, they would appear to have fallen in a still greater proportion.

---

[1] So small a sum as two shillings and elevenpence would be sufficient for this purpose if the machine would last for 100 years; for an annuity of two shillings and elevenpence, accumulating for 100 years at ten per cent., would at the end of that period amount to L.20,000.

Profits vary inversely as wages.

Hence it is plain, that while other things remain the same, profits vary inversely as wages—that is, they fall when wages really rise, and rise when wages really fall. But, owing to the different and ever-varying proportions in which fixed and circulating capital and immediate labour are employed in the production of commodities, it is extremely difficult to discover the precise extent to which any given fluctuation in the rate of wages affects profits. We shall, however, state three different cases, which will briefly, and, it is hoped, satisfactorily, elucidate the manner in which fluctuations in the rate of wages always operate, and the method to be followed in estimating their influence on profits.

Method of estimating the effects of fluctuations in the rate of wages on profits.

1. If all commodities were produced by immediate labour, or by capital employed in the payment of wages, it is obvious that every rise of wages would cause an equal fall of profits. A capitalist who employed L.1000 in the payment of wages must, if profits were at ten per cent., sell the commodities at L.1100. But when wages rise five per cent., or to L.1050, he would not be able to sell his commodities for more than L.1100; for money is itself a commodity, and as, by the supposition, all commodities are produced by immediate labour, the rise of wages would affect the producers of money in the same degree that it affects other producers. In this case, therefore, it is plain that a rise of wages will equally sink profits, and that a fall of wages will equally raise them.

2. If all commodities were produced, *half* by immediate labour, and the *other half* by capital, profits would only fall to half the extent that wages rose. Suppose a capitalist employs L.500 in the payment of wages, and L.500 as a fixed capital, when profits are at ten per cent., the commodities produced must, as before, sell for L.1100. If wages rose five per cent., the capitalist would have to pay L.525 as wages, and would, consequently, retain only L.75 as profit. In this case, therefore, a rise of wages to the extent of five per cent. would, because of equal quantities of capital and immediate labour being employed in the production of commodities, only sink profits two and half per cent.

3. If *all* commodities were produced by capital of a high degree of durability, capitalists, it is obvious, would not be at all affected by a rise of wages, and profits would, of course, continue as before.

Now, suppose that commodities, instead of being wholly produced by immediate labour, as in the first case, or wholly by equal quantities of immediate labour and of capital, as in the second, or wholly by fixed capital, as in the third, are partly produced in the one mode and partly in the other, and let us see what effect an increase of five per cent. in the rate of wages would have on their relative values. To facilitate this inquiry, we shall distinguish these three descriptions of commodities by the Nos. 1, 2, and 3. Now, it is quite evident that the rise of wages has affected No. 1 two and a half per cent. more than it has affected No. 2, and five per cent. more than it has affected No. 3. No. 1 must, therefore, as compared with No 2, have risen two and a half per cent. in value, and, as compared with No. 3, it must have risen five per cent.; No. 2 must have fallen two and a half per cent. as compared with No. 1, and risen two and a half per cent. as compared with No. 3; and No. 3 must have fallen five per cent. as compared with No. 1, and two and a half per cent. as compared with No. 2. If wages, instead of rising, had fallen, the same effects would obviously have been produced, but in a reverse order. The proprietors of the commodities of the class No. 1 would gain five per cent. by the fall, those of No. 2 would gain two and a half per cent., and those of No. 3 nothing; and the relative values of their commodities would be adjusted accordingly.[1]

General rule on the subject of all fluctuations.

Thus, then, it appears, inasmuch as a commodity taken for a standard by which to estimate the values of other commodities must itself be produced by capital returnable in a certain period, that when wages rise those commodities which are produced by less durable capitals than those which produce the standard will rise in exchangeable value, and those produced by more durable capitals will fall; and conversely when wages are reduced. Suppose, as before, that the Nos. 1, 2, 3, 4, 5, 6, 7, 8, 9, and 10, represent capitals of corresponding degrees of durability: If a commodity produced by the least durable capital No. 1, which may be supposed to be wholly employed in the payment of wages, be taken for a standard, all commodities produced by the other and more durable capitals would fall in value when wages rose; and if we suppose those produced by No. 2 to decline one per cent., those produced by No. 3 would decline two per cent., those produced by No. 4 three per cent., and so on until we arrive at No. 10, which will have fallen nine per cent. If, on the other hand, a commodity produced by the most durable capital No. 10, which may be supposed to consist wholly of highly durable machinery, be made the standard, all the commodities produced by the other and less durable capitals would rise when wages rise; and if those produced by No. 9 rose one per cent., those produced by No. 8 would rise two per cent., and those produced by No. 1 nine per cent. If a commodity produced by capital of a medium degree of durability, as No. 5, which may be supposed to consist half of circulating capital employed in the payment of wages, and half of fixed capital or machinery, be taken as a standard, the commodities produced by the less durable capitals, Nos. 4, 3, 2, and 1, will rise with a rise of wages, on the former hypothesis,—the first, or No. 4, one per cent., the second, or No. 3, two per cent., &c.; while those produced by the more durable capitals, Nos. 6, 7, 8, 9, and 10, will fall,—the first, or No. 6, one per cent., the second, or No. 7, two per cent., &c., exactly the reverse of the other.

Hence it is obvious that the influence which variations in the rate of wages have on price will principally depend on the nature of the capital employed in the production of gold and silver. Whatever may be the proportions of circulating and fixed capital employed in the production of money, all commodities produced by the agency of a greater quantity of manual labour, and with less fixed capital and machinery, will rise when wages rise, and fall when wages fall; but those that are produced by the agency of a less quantity of manual labour, and with more fixed capital or machinery, will fall when wages rise, and rise when wages fall. Those that are produced in nearly the same circumstances, or by the agency of the same quantities of circulating and fixed capital as money, will not be affected by fluctuations of wages.

It should be observed, however, that variations in the values of most commodities, caused by variations in the

---

[1] These examples are substantially the same with those given by Mr James Mill. See *Elements of Political Economy*, p. 77.

Variations of exchangeable value caused by fluctuations in the rate of wages confined within narrow limits.

rate of proportional wages, are confined within comparatively narrow limits. It has been seen that were all commodities produced wholly by immediate labour, or wholly by capital, or wholly by equal quantities of both, variations of wages would have no influence on their value. But a very large class of commodities are produced by means of nearly equal portions of fixed and circulating capital; and as every rise of real wages that may take place under such circumstances will be balanced by a fall in the rate of profit, or by a proportional increase in the productiveness of industry, it is evident that the value of the commodities in question, as compared with each other, would remain nearly stationary. Although, therefore, a rise of wages has a necessary tendency to raise the exchangeable value of one class of commodities, and consequently to lower that of another, the fall of profits, which inevitably follows every rise of wages that is not accompanied by an increased productiveness of industry, has a contrary effect, and tends to sink the value of the commodities which the increased rate of wages would raise, and to elevate the value of those which the same increased rate would sink. And it is only in extreme cases, or in the case of commodities produced almost wholly by direct manual labour on the one hand, or in that of those produced almost wholly by the aid of fixed capital or machinery on the other, that a variation in the rate of wages occasions a considerable variation in their values.

It must also be observed, that though fluctuations in the rate of wages may occasion variations in the values of particular commodities, they neither add to nor take from the total value of the entire mass. If they increase the value of those produced by the least durable capitals, they equally diminish the value of those produced by the more durable capitals. Their aggregate value continues, therefore, the same after a rise or fall of wages as before. And though it may not be strictly true of a particular commodity, that its exchangeable value is directly as its cost or real value, or as the quantity of labour required to produce it and bring it to market, it is most true to affirm this of the mass of commodities taken together.

In thus endeavouring to trace the cost of all descriptions of non-monopolized commodities to the quantity of labour required for their production, it is not meant to deny that a very large portion of the useful or desirable qualities of such commodities may be the result of the action or influence of natural agents. But it is, as was previously seen, the peculiar and distinguishing feature of natural agents or powers, that they render their services gratuitously. Whatever they do is done without fee or reward. And hence, though their co-operation be necessary to the production of all things that are either useful or desirable, they add nothing to their value. This is a quality that can be communicated only by the labour of man, or by the capital appropriated or accumulated by his labour. In estimating, for example, the cost or value of a quantity of corn, we include only the wages paid to the individuals employed in raising it, as ploughmen, reapers, thrashers, &c., with the value of the corn used as seed, and that of the services rendered by the horses and instruments made use of in the different operations. The influence of the vegetative powers of nature, and of the sun and showers, is ignored, or goes for nothing; for though without their powerful assistance the crop could not be obtained, and our utmost exertions would be altogether fruitless, yet, as they are the free gift of Providence, they add nothing to the value of the produce,—that is, they add nothing to its power of exchanging for or buying labour, or other things procured by the intervention of labour.

It may be thought, perhaps, that this principle is at variance with what is observed to take place in the production of certain descriptions of commodities. Thus, if a cask of new wine be kept for a definite period, or till it arrive at maturity, it will acquire a higher value: now, as the change produced on the wine is entirely brought about by the operation of natural agents, and as without the change the wine would have no higher value, it has been contended that this is a case in which the labour of natural agents is plainly productive of an increased value. It is easy, however, to see that this is a mistake. The cask of wine is a capital, being the result of the labour employed in cultivating, gathering, pressing, and otherwise preparing the grapes from which it was made. But the processes of fermentation, decomposition, &c., do not act instantaneously; and to enable them to effect the changes in the wine, it is necessary that it should be laid aside until they are completed. The merchant would not, however, employ his capital in this way, unless it were to yield the same return as other businesses. And hence, though the processes carried on inside the cask render the wine more desirable without adding anything to its value, the latter is increased by the amount of profit accruing on the capital subjected to the processes.

In estimating the cost of grinding corn, or spinning cotton, or forging anchors by the agency of wind or water-wheels, nothing is set down to the account of the wind or water. And such is invariably the case. Natural powers, however efficient and indispensable, are always left out of view in estimating the value of the products or results of undertakings. That is wholly dependent on the labour, including capital necessarily expended in bringing them about.[1]

Sect. V.—*Division of the Produce of Industry, under deduction of Rent, between Capitalists and Workmen.—Definition of Profits.—Mr Ricardo's Theory of Profits; Sense in which it is true.—Causes which occasion a Rise or a Fall of Profits.—Influence of the Decreasing Fertility of the Soil and of Taxation on Profits.*

Division of the produce of industry between capitalists and workmen.

Before attempting to investigate the circumstances which determine the rate of profit, it is necessary to be aware of those which determine the proportions in which the whole produce of industry, under deduction of rent, is divided between labourers and capitalists.

This preliminary inquiry may be disposed of in a few words. We have seen that the whole produce of the land and labour of every civilized society is always divided, in the first instance, into three, and not more than three, portions; the first of which goes to the labourers, the second to the capitalists or proprietors of stock, and the third to the landlords; and we have also seen that the portion of the produce of industry, or the rent, which belongs to the landlords, as proprietors of the soil, and not as capitalists, is altogether extrinsic to the cost of production; and that, though the landlords were to give it up, such self-immolation on their part would not occasion any change in the productiveness of industry, or any reduction in the price of raw produce. Supposing, then, that rent is deducted or set aside, it is obvious that the remaining produce of the land and labour of every country must be primarily divided between the two great classes of labourers and capitalists. And it is further obvious that were there no taxes in a country, or were the rate of taxation invariable, the proportion of the entire produce of industry, under deduction of rent, falling to the share of the labourers, could not be increased except by an equivalent reduction in the proportion falling to the share of the capitalists, and *vice versa*. Suppose, still better to illustrate this proposition, that the whole produce of industry in Great Britain is represented by the number 1000; suppose, farther, that the landlords get 200 of this sum as rent, and that the remaining 800 is divided in equal portions between labourers and capitalists. Under these circumstances, it is obvious that nothing could be added to the proportion of the produce, or to the 400, falling to the labourers, except at the expense of the capitalists; nor to the proportion, or 400, falling to the latter, except at the expense of the former.

---

[1] Sir William Petty stated, so early as 1667, that the value of commodities is always regulated by the quantity of labour required to produce them; there is, however, the same difference between his statements and the analysis and investigations of Mr Ricardo, whom we have principally followed in this section, that there is between the conjectures of Pythagoras respecting the true system of the world, and the demonstrations of Newton. But as the statement of Petty is curious, we subjoin it:—"If," says he, "a man can bring to London an ounce of silver out of the earth in Peru in the same time that he can produce a bushel of corn, then one is the natural price of the other; now, if, by reason of new and more easy mines, a man can get two ounces of silver as easily as formerly he did one, then corn will be as cheap at 10s. the bushel as it was before at 5s., *cæteris paribus*." (*Treatise of Taxes and Contributions*, ed. 1679, p. 31.)

Whether the 800 were increased to 1600, or reduced to 400, so long as those between whom it must be divided receive each a half, their relative condition must continue the same. And hence the propriety of distinguishing between proportional and real wages, that is, between wages estimated in parts of the produce raised by the labourer, and those estimated in definite quantities of money or produce. If the productiveness of industry were to diminish, proportional wages might rise, notwithstanding that real wages, or the amount of the produce of industry received by the labourer, might be diminished; and if, on the other hand, the productiveness of industry were to increase, proportional wages might be diminished, while real wages might at the same time be increased.

Hence it follows that, were taxation unknown or constant, the whole produce of industry, under deduction of rent, would be divided between capitalists and labourers; and that the proportion thereof falling to either party would vary inversely as the proportion falling to the other—that is, the proportion falling to the capitalists would be increased when that falling to the labourers was diminished, and diminished when it was increased.

Definition of profits.

Profits must not, however, be confounded with the produce of industry primarily received by capitalists. They really consist of that produce, or its value, which remains to the capitalists, after their necessary payments to others have been deducted, and after the capital wasted or used in industrial undertakings has been replaced. If the produce derived from an undertaking, after defraying the necessary outlay, be insufficient to replace the capital expended, a loss will have been incurred; if the capital be merely replaced, and there is no surplus, there will be neither loss nor profit; and the greater the surplus, the greater of course will be the profit. Profits are not measured by the proportion which they bear to the rate of wages, but by the proportion which they bear to the capital by the agency of which they have been produced. Suppose an individual employs a capital equivalent to 1000 quarters of corn in the cultivation of a farm, that he expends 700 quarters in the payment of wages and 300 in seed and other outgoings, and that the return to this capital is 1200 quarters. Under these circumstances, the proportion of the produce falling to the labourers as wages will be to that falling to the capitalists as seven to two; for of the 1200 quarters that go in the first instance to the capitalist, 200 only are profits, 1000 being required to replace the capital he has expended. In this case, therefore, the rate of profit would be said to be twenty per cent., meaning that the excess of produce belonging to the cultivator, after the capital employed in its production was fully replaced, amounted to twenty per cent. upon that capital.

Mr Ricardo's theory of profits.

We have been thus particular with respect to the definition of profits, because, from not keeping it sufficiently in view, Mr Ricardo has been led to contend that a rise of profits cannot be brought about except by a fall of wages, nor a fall of profits except by a corresponding rise of wages. It is evident, however, that this theory is true only in the event of our attaching a radically different sense to the term profit from what is usually attached to it, and supposing it to mean the proportion of the produce which goes to the share of the capitalist, without reference to the ratio which it bears to the capital employed in its production. If we understand the terms in this sense, Ricardo's theory will hold universally; and it may be affirmed that so long as the proportion in which the produce of industry, under deduction of rent, is divided between capitalists and labourers, continues the same, no increase or diminution of the amount of that produce, or of the powers of production, will occasion any variation in the rate of profit. But if we consider profits in the light in which they are invariably considered in the real business of life—as the produce accruing to the capitalists after the capital expended by them in payments and outgoings of all sorts is fully replaced—it will immediately be seen that there are innumerable exceptions to Ricardo's theory.

Profits in agriculture.

It will facilitate the acquisition of precise ideas respecting the circumstances which determine the rate of profit in different employments, as that term is commonly understood, if we confine our attention, in the first place, to those which determine profits in agriculture,—both because the latter admit of being accurately measured, and because they may be taken as representing profits in other businesses. Agriculture is a branch of industry that must be carried on at all times, and under all circumstances; but it would not be carried on unless it did, at an average, yield as great a return to the capital vested in it as other businesses; nor would the latter be carried on if they yielded a less return than is derived from agriculture. Hence it follows that the returns obtained from agricultural industry or agricultural profits may, in ordinary cases, be considered as identical with the returns or profits obtained from other businesses. Whenever, for example, the average return to an outlay of capital or labour worth 100 quarters of wheat, employed in the cultivation of the soil, amounts to 110 quarters, we may safely infer that L.100 employed in manufactures is also yielding L.110; for a regard to their own interest will not permit those engaged in such departments to prosecute them for less profit than is obtained in agriculture, and the competition of the agriculturists will not permit them to obtain more.

Circumstances which occasion a rise or fall of profits.

Taking, then, as we are entitled to do, agricultural profits as a standard for profits in general, let us suppose that a landlord employs a capital equivalent to 10,000 quarters, or L.10,000, in the cultivation of an estate; that he expends 5000 quarters, or L.5000, of this capital in seed, in the keep of horses, and in defraying the wear and tear of implements and machines; and 5000 quarters, or L.5000, in paying the wages of labourers. Suppose, now, that the return obtained by this landlord is 12,000 quarters, or L.12,000; of which 10,000 quarters, or L.10,000, go to replace his capital, and 1000 quarters, or L.1000, to pay his taxes,—leaving 1000 quarters, or L.1000, as profits, being ten per cent. on the capital employed: it is plain from this case (and this case is, in point of principle, the actual case of all cultivators) that the rate of profit may be increased in three, but only in one or other of three, ways, —viz., 1, by a fall of wages; 2, by a fall of taxes; or, 3, by an increased productiveness of industry.

Thus it is obvious (1.), that if wages were reduced from 5000 to 4000 quarters, profits, supposing other things to continue the same, would be increased from 1000 to 2000 quarters, or from ten to twenty per cent.: if (2.) the burden of taxation were reduced from 1000 to 500 quarters, profits would be increased from 1000 to 1500 quarters, or from ten to fifteen per cent.: and if (3.), owing to the introduction of an improved system of agriculture, the return to a capital of 10,000 quarters were increased from 12,000 to 13,000 quarters, profits, supposing wages still to amount to 5000 and taxes to 1000 quarters, would be increased to 2000 quarters, or to twenty per cent.: And though, in this case, after the productiveness of industry had been increased, wages form a less proportion of the whole produce than they did previously, it is to be observed, that this less proportion is the consequence, and not the cause, of profits having risen; and, therefore, in such cases as this, and they are of very frequent occurrence, it is true to say, that proportional wages fall because profits rise: but the converse of the proposition is not true; for the rise of profits was occasioned by causes that had nothing whatever to do with wages, and which were, in fact, totally independent of them.

It is indeed true, inasmuch as the rise of profits is the result of an increased productiveness of industry, that the real value of the 13,000 quarters will not exceed the real value of the 12,000 previously obtained by the same quantity of labour; but profits, in the sense in which they are practically understood, and as we understand them, do not depend on real values, but on the excess of the commodities produced above the capital expended in their production; and whenever this excess is augmented, without any previous depression of the rate of wages, the rate of profit is evidently increased by the operation of causes extrinsic to variations in that rate.

Nor is this all. The rate of profit may remain stationary, or rise, though the proportion of the produce of industry falling to the share of the labourer be actually increased. Suppose, to exemplify this, that a landlord employs 1000 quarters of wheat as a capital, 500 of which are expended in seed, keep of horses, &c., and 500 in paying wages; if the produce be 1200 quarters, and the taxes to which he is subjected 100, his profits will amount to 100 quarters, or ten per cent.: suppose now that, owing to the introduction of improved machinery, or improved methods of culture, he only requires to expend 400 quarters in seed, keep of horses, &c., but that wages rise from 500 to 550 quarters, and that the same return is obtained; in this case, supposing taxation to be constant, the profits of the landlord will be increased from ten to fifteen three-fourths per cent., though proportional wages have risen from five-twelfths to five and a half twelfths of the whole produce.

If this increased productiveness were confined to agriculture, without extending to other important businesses, the price of agricultural produce would fall, while that of other produce would remain stationary; and, in such a case, it may be said that the profits of the agriculturists, if estimated in money, or in any commodity other than corn, would be diminished in consequence of the rise of wages. This is true; but Ricardo made no exception, in laying down his theory, in favour of those possible, and indeed frequently occurring cases, when, from any single circumstance, or combination of various circumstances, industry becomes generally more productive, and when, consequently, profits generally rise, without that rise being occasioned by a fall of wages. And it is also true, that an increased productiveness of agriculture, whether caused by improvements made in it, or by the repeal of restrictions on the importation of corn, most commonly extends itself to other businesses, and has the effect of bringing about an universal rise of profits; for, as farm produce forms the principal part of the labourer's subsistence, and as he obtains a larger quantity thereof in exchange for the same amount of money after it has fallen in price, his condition is in so far improved; and a stimulus being, in this way, given to population, the supply of labour is increased, and wages being reduced, the rate of profit is universally raised.

When industry, instead of becoming more becomes less productive, the opposite effects follow. Profits then fall, without any fall having previously taken place in the rate of wages. It is evident, therefore, that the proposition that a rise of profits cannot be brought about otherwise than by a fall of wages, nor a fall of profits otherwise than by a rise of wages, is true only in those cases in which the productiveness of industry and the burden of taxation remain constant. So long as this is the case, or, which is the same thing, so long as the same capital is employed, and the same quantity of produce has to be divided between capitalists and labourers, the share of the one cannot be increased without that of the other being equally diminished: and, it is also true, that if profits depended on the division of the produce of industry between capitalists and labourers, they could not be affected by variations in its productiveness, but would be determined wholly by the proportion of the produce set apart as wages. But profits depend, as has been already seen, on none of these things, but on the proportion which they bear to the capital by which they are produced. Suppose an individual employs a capital of 1000 quarters, or L.1000, in cultivation; that he lays out half this capital in the payment of wages, and obtains a return of 1200 quarters, or L.1200; in this case, assuming he is not affected by taxation, his profits will amount to 200 quarters, or L.200, being at the rate of twenty per cent., and will be to wages in the proportion of two to five. Suppose, now, that the productiveness of industry is universally doubled, and let it be farther supposed, that the additional 1200 quarters, or L.1200, is divided between the capitalist and his labourers in the former proportion of two to five, or that the capitalist gets 343 quarters, or L.343, of additional profits, and the labourers 857 quarters, or L.857, of additional wages: in this case, both parties will still obtain the same proportions of the produce of industry as before; and if we look only to them, we must say that neither profits nor wages have risen. But when we compare, as is invariably done in estimating profits, the return obtained by the capitalist with the capital he employs, it will be found, notwithstanding the constancy of proportional wages, that the rate of profit has really increased from twenty to fifty-four per cent.

Thus, then, it appears, as was previously stated, that profits rise in one or other of the three following ways, viz.,—(1.), from a fall of wages; (2.) from a fall of taxes, directly or indirectly affecting capitalists; or (3.), from an increased productiveness of industry: and they fall (1.), from a rise of wages; or (2.), from an increase of taxes; or (3.), from a diminished productiveness of industry. But they can neither rise nor fall, except from the operation of one or more of the causes now stated.

Extra profits—on what they depend.

In the previous observations we have, to simplify the subject, considered profits as arising from the employment of capital by persons of ordinary skill and intelligence in the usual pursuits of industry. But, in addition to these, very considerable amounts of capital are employed by parties who possess superior knowledge and ability in the callings in which they engage, and who, in consequence, obtain proportionally large returns. It has been disputed whether these extraordinary returns should be considered as profits or wages. And we are disposed to think that, in as far as they result from the better training and instruction of those who superintend the employment of the capital, they should be considered as the profit upon, or return to, the extra outlay on their education. But in cases where the parties possess, as they sometimes do, any peculiar talent or genius, by which they are enabled to strike out new and better methods of production, the results must be considered as the fruit of natural gifts of which they are the exclusive possessors. The profits realized by such parties are not subject to any ordinary rule or law. Everything depends on the peculiar genius and intelligence with which they are endowed. If it be far above the common level, and applicable to the production of articles or services for which there is a great demand, their gains will be proportionally great, and may far exceed, even when the things they supply have little intrinsic worth, those realized by ordinary people.

But though these extra profits are always being made, and amount in the aggregate to a very great sum, yet there are no good grounds for thinking that they bear any very large proportion to the vast amount of profits produced in businesses and professions conducted in the ordinary way, and with ordinary talent and attention. And it is also to be borne in mind that if there be, on the one hand, individuals who, by dint of superior skill and ability, make large profits and accumulate fortunes, there are, on the other hand, a great number of individuals who, from want of the requisite capacity or care, make little or no profit, and not unfrequently sink into the abyss of bankruptcy. The losses incurred by the latter class go far to balance, if they do not exceed, the extraordinary gains of the other. And though fortunes made, like those of Arkwright and Watt, by the exertion of genius and invention, attract and fix the public attention ; yet there can be no manner of doubt that the great bulk of the public wealth is the result of ordinary skill and industry, backed up and assisted by the general disposition to save and amass. For one fortune that owes its existence to superior talent, ten owe theirs to a long-continued course of economy. But having already seen that parsimony is the main source of national riches, it is needless to enlarge further on this topic.

Influence of the decreasing fertility of the soil on profits.
